In 1943–44 there was an epidemic of a mild kind of encephalitis, from which the majority recovered. Scarlet fever and diphtheria occurred, and followed a normal course; there was a plentiful supply of serum for treating the latter, but postdiphtheritic paralysis appeared to be a more frequent complication than usual. Mumps was common, with frequent orchitis; whooping-cough was rare. Pneumonia, said to have been mainly bronchopneumonic with few physical signs, was responsible for a large morbidity; recurrences were common, but the number of deaths "not as great as expected." Tuberculosis was very prevalent, usually with an insidious onset and rapid course; effusions were frequent and the spread was most often miliary. Many cases were not diagnosed until necropsy, as was also the case at Belsen.

In the final month of the war there came the inevitable consignment of about 1000 emaciated, verminous, and typhus-ridden prisoners who, as at Belsen, were simply turned loose in the camp. An epidemic followed, with about 30 new cases a day; but before the liberation, the number had dropped to 4–5 daily. As elsewhere in Europe where typhus appeared in 1945, the disease carried a much lower mortality than the epidemics of 1918; despite the evident poor resistance of the inmates and absence of previous immunisation, the mortality was only 15–20%.

DEATHS

The author gives some official statistics for the number of deaths between January, 1942, and April, 1944; these are illustrated by the following round figures, derived from his tables, which relate to a population of 30,000–60,000 in the twelve months between August, 1942, and July, 1943:

	No. of deaths
"Old age"	5400
"Enteritis"	7800
Pneumonia	4000
Tuberculosis	500
Total from all causes	23,200

"Old age" of course included many nutritional deaths, and "enteritis" included deaths from both enteric fever and famine diarrhœa.

NATURE OF NUTRITIONAL DISORDERS

In discussing the ætiology of the nutritional disorders he observed, Wolff-Eisner introduces a number of concepts that will seem strange to those accustomed to the recent Anglo-American literature, with which, understandably enough, he appears to be unfamiliar. He revives an old German idea that deficiency of fat is an important factor in the ætiology of famine œdema, and he does not indicate that reduced plasma-albumin, resulting from insufficient protein intake, may itself be a cause of œdema. He believes that some disturbance of the reticulo-endothelial system affects the albumin-globulin ratio and is responsible for the formation of tissue exudates and the rapid erythrocyte-sedimentation rate in starving people. He insists that simple lack of calories was not a significant factor in the mortality and that vitamin deficiencies were much more important—despite the fact that his descriptions provide no certain evidence of such deficiencies except for hemeralopia and the mention of cases of pellagra. He admits that yeast was distributed in the camp without effect on morbidity, but argues that this showed how very great was the deficiency of vitamin B.

Translated into practical terms, he feels that what the prisoners needed most was not more carbohydrate but more meat, fish, fat, fruit, and vegetables. With this conclusion there can be no quarrel; such protective foods would certainly be the best remedy for a starvation diet, as sources of both calories and essential nutrients. But his reasons for the conclusion are less convincing. General experience is that vitamin deficiencies are rare with severe under-feeding, probably because the need for most vitamins diminishes as the calorie intake lessens.

PHYSICAL ANTHROPOLOGY

FROM A CORRESPONDENT IN NEW YORK

THE Viking Fund, of New York City, under the direction of Dr. Paul Fejos, has been supporting anthropological research for a good many years, but it is only recently that its efforts at stimulating physical as well as cultural anthropology have brought its activities to the attention of those in the medical field.

This summer, for the third year in succession, the Fund has financed a seminar, which discussed two subjects, each for five days; the first was Growth, and the second Evolution. The official discussants, whose expenses are paid by the Fund, included one British expert in each field: Dr. J. M. Tanner on growth, and Prof. W. E. Le Gros Clark, F.R.S., on evolution.

in the interest of health; or (4) have undergone double amputation and need an invalid chair for indoor use to afford relief from the wearing of artificial limbs.

Replacements and repairs (except of artificial limbs, and invalid chairs and tricycles, for which the Ministry of Pensions is responsible) will be done through a hospital. But to relieve hospitals, minor defects not affecting function will be referred by the patient to the Ministry of Pensions regional office or sub-office, which will arrange for the repair to be done and the appliance returned to the patient. The liability of the patient to pay for replacements or repairs occasioned by carelessness will be decided by hospital management committees or boards of governors; and the patient will have the right to appear before the committee or board. Patients under treatment in private blocks will be entitled to the free issue of appliances; and it will be for regional boards to ensure that hospitals outside the service with whom they have contractual arrangements for the treatment of patients are able to obtain any necessary appliances for these patients.

LIFE AND DEATH IN A CONCENTRATION CAMP

THE clinical consequences of famine have been well described by several British doctors released from Japanese prison camps.[1] But in Europe, where starvation diets have usually consisted of black bread (baked from wheat or rye and often adulterated with barley, potato flour, or even sawdust), bean soup, and variable amounts of potatoes and other root vegetables, the pattern of deficiency disease differs from the pattern in the Far East, where polished rice is preponderant. Since famine is rare in Europe, and the doctors on the spot have seldom had the time or experience to make careful records, good clinical observations are scarce, and those made by Dr. Wolff-Eisner[2] while a prisoner in Theresienstadt concentration camp are correspondingly valuable.

Wolff-Eisner is well known in Germany for his work in clinical serology. Born in 1877, he was a professor of internal medicine in the University of Berlin, and sub-chief of the Robert Koch Institute, until his imprisonment by the Nazis. Since his release he has become medical director of the Schwabinger Hospital for Displaced Persons in Munich and director of the serological laboratory of the Munich University clinic for nervous diseases.

DESCRIPTION OF THE CAMP

Theresienstadt, an old fortress near Vienna, was a "privileged" concentration camp intended primarily for elderly Jews. The inmates, increasing from 30,000 to 60,000 between 1942 and 1945, came mainly from Germany but also from Denmark and Holland. In addition there were some, of all ages, from Czechoslovakia. It seems that at first conditions were reasonably humane. The buildings, though antiquated (mainly 18th century) and poorly ventilated, were adequate. The inmates had a certain degree of self-government; small food parcels were occasionally received from relatives outside Germany, and the camp was inspected by observers from neutral countries. A little smuggled money was in circulation. The medical service, staffed by imprisoned university teachers, had a hospital of 5000 beds with good X-ray and routine laboratory facilities, except that, significantly, no bacteriology was permitted.

Gradually, however, the typical story unfolded. More and more prisoners arrived, often in a dreadful condition after appalling journeys in cattle-trucks from various transit camps. (Wolff-Eisner quotes a heartrending account by Dr. Roland, who accompanied Paul Ehrlich's son on one such journey.) The camp became overcrowded; the food deteriorated; disease increased; and fleas, lice, and bedbugs swarmed everywhere, so that many preferred to sleep in the cold out of doors. As prisoners died they were rapidly replaced by new arrivals. Large numbers, estimated by Wolff-Eisner at more than 80,000, were taken off to Birkenau and Auschwitz for extermination. Last of all came the typhus. The end-result must sound very familiar to those who saw Belsen at the time of its liberation—people crowded into 3-tier bunks, those on the upper levels often too weak to move, with intractable diarrhœa, covered with vermin, and out of reach of medical care.

THE CAMP DIET

The official diet of those "over age" provided 330 g. of bread daily, with only 50–60 g. of fat and sugar weekly. The daily allowance of potatoes was 180–250 g., but these were often unwholesome. A "lentil extract" soup, of doubtful nutritional value, was especially dreaded for its laxative properties. Small quantities of other foods brought the official calorie-value of the rations up to 1650 a head daily, but there must have been very many who got nothing like this amount, especially as the leaders among the prisoners saw to it that children and workers had more than their official share. Then there was the inevitable black market around the kitchen, and the potato-peelers were often found stealing potatoes or eating them raw, with subsequent diarrhœa in retribution. When it is considered that many of the prisoners had undergone much privation before arrival, it is not surprising that nutritional disorders soon began to appear.

Most of the prisoners became thin, losing up to 30–40% of their original weight. This, probably aided by frequent coughs, resulted in a high incidence of new hernias. Nocturia (4–5 times in a night) Wolff-Eisner puts down to "irritable bladder," but it was more probably part of the polyuria which precedes famine œdema. "Socially unpleasant" flatulence, ascribed to the high-carbohydrate diet, was always troublesome and persisted for months after liberation and return to a good diet. Hemeralopia, attributed primarily to the low fat intake, was very common and is said to have responded "fairly well" to the administration of vitamin-A concentrates. Curiously enough, glaucoma also appears to have been common, even among young people, and a number of cases were successfully treated by operation. At times the majority of inmates suffered from an intractable conjunctivitis which sometimes left permanent damage to the cornea. Skin infections such as impetigo, furunculosis, and carbuncles, were very troublesome; and therapeutic injections often caused abscesses. Scabies is not recorded (it was also uncommon in Belsen). Frequent bedsores, atrophy of the skin, loss of hair and of its natural gloss, brittle nails, dysphagia, and loose teeth are other conditions mentioned.

INTESTINAL DISORDERS

Among the "special diseases" of Theresienstadt, enteritis was the most dreaded. The onset was usually a simple attack of diarrhœa, often with some fever and perhaps the result of a simple infection; but the diarrhœa might persist and the patient sometimes died. The stools were bulky, paler than usual, foamy and highly acid, but (naturally, in view of the diet) contained little fat; blood or mucus were rarely seen. Wolff-Eisner is undoubtedly right in thinking that this condition was due to nutritional deficiency rather than any specific dysenteric infection. It seems to have been identical with the "famine diarrhœa" with which workers at Belsen and in the Bengal famine became so familiar. He remarks on the frequency of osteoporosis and spontaneous

Disabilities

10. THE ALCOHOLIC *

A person who has lost the sight of an eye, or who has had a leg amputated, is forced to face the fact that he must adjust his life to suit his disability. It is the same with an alcoholic, who must also learn to accept his disability. Leaving aside the question of any higher power, nothing stands between him and the ravages of his disease but his own will. No-one can cure an alcoholic: he is incurable. No-one but himself can reclaim him, and the first step in his reclamation must be the realisation that he is suffering from an incurable disease. Unlike his fellow men, the heavy drinkers and the light drinkers, he alone can ensure (in the words of Alcoholics Anonymous) that he " never takes the first drink."

What is an alcoholic ? To me, as a layman, he is a person who has no control over himself where alcohol is concerned. Give him one drink and he will drown his body, his mind, and his reputation in alcohol and will go down for the third time still drinking. A drunk may drink until he passes out, but he will learn his lesson. An alcoholic can never learn his lesson, as long as he drinks.

How does one become an alcoholic ? I suppose there are many ways, just as there are many degrees of alcoholism. I can only give my own experience. An alcoholic will always find something other than himself to blame, and I was no exception to the rule—the war (1914–18) ; the peace ; prohibition in America ; business worries ; an unfortunate love affair ; and again the war. I started drinking whisky as a young soldier at the age of 16½. It was fun to get drunk, and what did it matter ? One might be dead tomorrow. By the time the war ended I was used to drinking. It was still fun, and in the London of the 'twenties there were always parties, so why not get drunk ? During prohibition in America everybody drank all they could get. So again, why not ? The fact remains that, though I did not know it at the time, I was an alcoholic from the moment I took my first drink.

It took a good many years for the thing to creep up on me, and a good many more for me to realise it. From the enjoyment of a party, with a good deal to drink and a reasonably clear head the next day, came the foregone conclusion that I would get drunk, and pay for it with a monumental hangover. It was a short step from there to the morning drink (the hair of the dog) to cure the hangover and eventually to lead to the next one.

I began to dread parties. I knew that my friends bore with me only because of affection for my wife, a great tolerance, and the fact that I usually passed out quietly without particularly bothering anyone. In the mornings I remembered nothing. It was only by artful games of cross questions and crooked answers with my wife that I found out what had happened—what gaffes I had committed, what decantings into taxis, what fallings down stairs, what hundred and one shaming episodes which still did not build up into one warning big enough for me to see.

By this time I was in a pretty bad state physically. I was either not sleeping at all or sleeping for a few hours and waking with a jerk, to lie shaking with nerves for the rest of the night. I had become antisocial, avoiding my friends and the company of people who knew me. When actually drinking I would talk to anyone who would talk to me, but I usually chose someone of a lower social level, probably because it gave me a much-needed feeling of superiority. I was intolerant of criticism, my attitude in general being " If you don't approve of my behaviour it shows what a fool *you* are."

As to why I was drinking, I don't really know. To escape from situations which I did not like and which I knew, inwardly, were of my own making. My home life, such as it was, was unhappy. My wife nagged, because she was frightened and I was practically impotent sexually. I had a continuous craving for excitement, emotional experiences, and friendships. I longed to escape from the boredom and worries of everyday life and the dissatisfaction with my job, which was in turn caused by my drinking. The more I drank the less I found what I wanted or was capable of responding to it if I found it. I was in a vicious cage, from which the only escape seemed to be drink.

Finally, to use a cinema cliché, " came the dawn." I woke one morning feeling worse than ever before. I remembered nothing. I didn't know where I was and I had no money in my pockets. I knew, not for the first time, that I was playing ducks and drakes with my future and was likely to lose my job at any minute. I swore I would never take another drink—but what was the use ? I had done that before. Maybe I wouldn't drink for a while, but sooner or later, at the most unlikely moment (probably) I would take the first drink. The merry-go-round would start, and I should be a passenger until such time as it chose to stop.

It was then that I sought out Alcoholics Anonymous (A.A. to its members) and learnt the two slogans which were to be—which are to be, please God—my salvation. The first is, " Never take the first drink," but the second is the more important : " I won't have a drink *today* " —not for a week, not for a month, not never, but just today.

Most alcoholics are by nature convivial. They like the fun of social intercourse, of parties, of people, and by the very nature of their disease these things lead to the indulgence in alcohol which is, to them, fatal.

How then does an alcoholic who does not drink carry on with his normal life ? I was in the habit of going to a pub or a club in the evenings. Some of my fellow members of A.A. had, I knew, given up their drinking friends, resigned from their golf clubs, cut themselves off from all their normal outlets for relaxation. They had, in general, behaved like startled hermit crabs. I made up my mind that I would do no such thing. If I did, I would inevitably start drinking again from sheer boredom, which was about the one excuse I had never used.

I continued to see my friends, drunk and sober, but I didn't drink. If my friends bored me rather, when they were drunk, it was a useful yardstick to measure how boring I must have been to them.

At first I drank tomato juice, until I found that over-indulgence in that beverage had an effect different from but almost as uncomfortable as over-indulgence in alcohol. Thereafter I varied my temperance tipples —ginger beer if it was hot ; tomato juice if it was cold ; and as a standby gin and tonic without the gin. In bars where I am known, and where the double whisky used to be set up as I came through the door, I now order a double gin and tonic. This is an accepted joke, but if I tried to get the gin into it I would find myself involved in an embarrassing explanation with the barman, who knows and approves of what I am doing.

My friends, with one or two exceptions (who are not perhaps as good friends as I thought), are delighted. I know that, even if I begged for it, I wouldn't get a drink in their houses or in their company, and I'm proud of it. I am not, as I feared, a bore ; on the contrary, I was a bore before, but didn't know it.

There are, I have discovered, worse deprivations than that of alcohol, and freedom from it brings many and unexpected benefits. I now know that what can't be cured can be endured far more easily than I had thought. For the first time in years I feel well. My hand is steady

GROWTH

Human and animal growth has long been neglected by anatomists, physical anthropologists, and physiologists alike, despite the advantages inherent in studying anatomical structure or physiological function through its developmental phases, in biological time as well as space. In consequence, the first half of the seminar was essentially non-technical minutiæ. Set papers were given by Prof. H. C. Stuart on differential growth from the pædiatric viewpoint, Dr. F. E. Randall on the termination of growth in young males, Dr. Pauline Mack on diet and growth, and Dr. W. M. Krogman on general organisation and objectives of growth studies.

Professor Stuart described his own growth study in the school of public health at Harvard University. He gave it as his opinion that predominantly endomorphic or fat adults are plump as babies, and thin adults thin as babies, despite regular variations in the average fatness of the entire group during the growing period; and he remarked that the only sane way of diagnosing malnutrition in a child that he was aware of was the therapeutic test of response to a known optimal diet and environment over a period of about a month.

Dr. Randall, in measuring U.S. Army personnel, had found no increase in stature or sitting height after age 18, and none in chest girth, waist girth, bideltoid diameter, and weight after 28, in an under-40 group. In the following discussion it emerged that head length similarly ceased growth at 18, but head breadth or circumference, which included muscle and fat, continued growing into the twenties.

Dr. Mack gave some preliminary results from a most extensive study of growth and nutrition made in Philadelphia. She found that in orphanages weight and stature gains could be increased somewhat by dietary means even though the orphans were getting the, to us, high rations recommended by the National Research Council: the important factor was high-class animal protein. Family studies had also shown, amusingly enough, that when economic factors were held constant the best-nourished children next to old Americans were those with a German mother and an Irish father, and conversely the worst-nourished those with an Irish mother and a German father.

In the discussion following Dr. Krogman's paper the use of indices such as the cephalic index or height/weight index was attacked on biometric grounds by Dr. Tanner, who pointed out that such indices failed to do exactly that which they were supposed to—namely, rule out of consideration the aspect of general largeness in comparing two or more animals for build differences. There emerged a very general agreement on the undesirability of indices, in particular the cephalic index, and a strong interest in the methods of factor analysis as applied both to the classification of human physique and in relation to the classificatory problems of the taxonamist. There was unanimous condemnation as downright vicious of the use of simple height/weight tables for assessing the growth, build, or nutrition of children.

In the final summarising speech of this part of the conference, Dr. Tanner stressed the need for publication of the raw data of human growth studies: such data took twenty or thirty years and enormous amounts of money to collect, and yet in several instances had been reported in such a fragmentary way (owing on at least one occasion to the death of the collector) that only a fraction of the possible information had become available.

EVOLUTION

Evolution occupied five sessions, two of which were devoted to discussion of the recent fossil finds in South Africa and Kenya. This material was described by Professor Le Gros Clark, and the members of the seminar sent messages of thanks to the two anthropologists, Dr. Broom and Dr. Leakey, who were responsible for digging up these most valuable finds. It was most unfortunate that Prof. F. Weidenreich, one of the chief discussants, was prevented from attending by illness.

The ape status and erect posture of Australopithecus appeared to be a less disputable subject than on some previous occasions, and though Dr. Strauss, of Johns Hopkins University, still expressed a waning doubt that the hip-bone and the others were from the same animal, the majority were convinced.

Dr. A. H. Schultz gave a paper on evolutionary trends amongst the primates, in which again the question of relative growth as expressed by indices—the arm-length/trunk-length and similar ones this time—was raised, Dr. Erickson, of Harvard University, feeling this was an insufficient way to adjust for size differences between species. A factorial-analysis approach by pooling related species' measurements and using the factors to define new sets of species was adumbrated.

CENTRAL HEALTH SERVICES COUNCIL

The council held its first meeting on July 27, when Mr. F. Messer, M.P., was elected chairman and Prof. Henry Cohen vice-chairman. The members are:

EX OFFICIO

Lord Moran, M.C., M.D., president of Royal College of Physicians of London. Lord Webb-Johnson, K.C.V.O., C.B.E., D.S.O., president of Royal College of Surgeons of England. Sir William Gilliatt, C.V.O., M.D., M.S., president of Royal College of Obstetricians and Gynæcologists. Dr. H. G. Dain, chairman of council, British Medical Association. Sir Herbert Eason, C.B., C.M.G., M.D., M.S., president of General Medical Council. Dr. G. F. Buchan, F.R.C.P., chairman of council, Society of Medical Officers of Health.

MEDICAL PRACTITIONERS

Miss Janet Aitken, M.D., F.R.C.P., senior physician to Elizabeth Garrett Anderson Hospital. Prof. W. G. Barnard, F.R.C.P., dean of St. Thomas's Hospital medical school Mr. Aleck Bourne, F.R.C.S., F.R.C.O.G., gynæcologist to St. Mary's Hospital. Dr. J. A. Brown, general practitioner in Birmingham and vice-chairman of representative body, B.M.A. Sir Ernest Rock Carling, F.R.C.S., F.R.C.P., consulting surgeon to Westminster Hospital. Prof. Henry Cohen, F.R.C.P., physician to Liverpool Royal Infirmary. Dr. E. A. Gregg, general practitioner in London and chairman of representative body, B.M.A. Dr. W. V. Howells, anæsthetist to Swansea Hospital and member of council, B.M.A. Dr. Horace Joules, F.R.C.P., medical director of Central Middlesex Hospital. Prof. A. J. Lewis, F.R.C.P., director of clinical psychiatry, Maudsley Hospital. Dr. W. G. Masefield, C.B.E., formerly medical superintendent of Brentwood Mental Hospital. Dr. W. N. Pickles, M.R.C.P., general practitioner at Aysgarth, Yorks. Sir Harry Platt, M.S., M.D., professor of orthopædic surgery in University of Manchester. Prof. J. C. Spence, M.C., F.R.C.P., physician to Royal Victoria Infirmary, Newcastle-on-Tyne. Dr. C. W. Walker, general practitioner in Cambridge.

PERSONS WITH EXPERIENCE IN HOSPITAL MANAGEMENT

Mr. F. J. Cable, F.H.A. Mr. Clayton Fryers, C.B.E., F.H.A. The Hon. A. J. P. Howard, C.V.O., M.P. Sir Owen Morshead, K.C.V.O., D.S.O., M.C. Major-General Sir Harold Wernher, K.C.V.O.

PERSONS WITH EXPERIENCE IN LOCAL GOVERNMENT

Alderman A. F. Bradbeer. Sir Wynne Cemlyn Jones. Mr. Fred Messer, M.P., J.P. Mrs. Dorothy Turtle. Alderman W. E. Yorks, J.P.

DENTAL PRACTITIONERS

Mr. F. J. Ballard. Mr. Joseph Lauer, L.D.S., R.C.S. Mr. H. T. Roper-Hall, M.B., M.D.S.

PERSONS WITH EXPERIENCE IN MENTAL HEALTH SERVICES

Sir Cecil Oakes, C.B.E.

REGISTERED NURSES

Miss Eleanor J. Merry, S.R.N., S.C.M. Miss Mary E. G. Milne, O.B.E., S.R.N., S.C.M.

CERTIFIED MIDWIFE

Miss Nora B. Deane, M.B.E., S.R.N., S.C.M.

REGISTERED PHARMACISTS

Mr. R. H. Henriksen, A.R.I.C., M.P.S. Alderman W. J. Tristram, J.P., M.P.S.

There is one further appointment to be made. The secretary is Mr. E. J. S. Clarke of the Ministry of Health.

Disabilities

10. THE ALCOHOLIC *

A person who has lost the sight of an eye, or who has had a leg amputated, is forced to face the fact that he must adjust his life to suit his disability. It is the same with an alcoholic, who must also learn to accept his disability. Leaving aside the question of any higher power, nothing stands between him and the ravages of his disease but his own will. No-one can cure an alcoholic: he is incurable. No-one but himself can reclaim him, and the first step in his reclamation must be the realisation that he is suffering from an incurable disease. Unlike his fellow men, the heavy drinkers and the light drinkers, he alone can ensure (in the words of Alcoholics Anonymous) that he " never takes the first drink."

What is an alcoholic ? To me, as a layman, he is a person who has no control over himself where alcohol is concerned. Give him one drink and he will drown his body, his mind, and his reputation in alcohol and will go down for the third time still drinking. A drunk may drink until he passes out, but he will learn his lesson. An alcoholic can never learn his lesson, as long as he drinks.

How does one become an alcoholic ? I suppose there are many ways, just as there are many degrees of alcoholism. I can only give my own experience. An alcoholic will always find something other than himself to blame, and I was no exception to the rule—the war (1914–18); the peace ; prohibition in America ; business worries ; an unfortunate love affair ; and again the war. I started drinking whisky as a young soldier at the age of 16½. It was fun to get drunk, and what did it matter ? One might be dead tomorrow. By the time the war ended I was used to drinking. It was still fun, and in the London of the 'twenties there were always parties, so why not get drunk ? During prohibition in America everybody drank all they could get. So again, why not ? The fact remains that, though I did not know it at the time, I was an alcoholic from the moment I took my first drink.

It took a good many years for the thing to creep up on me, and a good many more for me to realise it. From the enjoyment of a party, with a good deal to drink and a reasonably clear head the next day, came the foregone conclusion that I would get drunk, and pay for it with a monumental hangover. It was a short step from there to the morning drink (the hair of the dog) to cure the hangover and eventually to lead to the next one.

I began to dread parties. I knew that my friends bore with me only because of affection for my wife, a great tolerance, and the fact that I usually passed out quietly without particularly bothering anyone. In the mornings I remembered nothing. It was only by artful games of cross questions and crooked answers with my wife that I found out what had happened—what gaffes I had committed, what decantings into taxis, what fallings down stairs, what hundred and one shaming episodes which still did not build up into one warning big enough for me to see.

By this time I was in a pretty bad state physically. I was either not sleeping at all or sleeping for a few hours and waking with a jerk, to lie shaking with nerves for the rest of the night. I had become antisocial, avoiding my friends and the company of people who knew me. When actually drinking I would talk to anyone who would talk to me, but I usually chose someone of a lower social level, probably because it gave me a much-needed feeling of superiority. I was intolerant of criticism, my attitude in general being " If you don't approve of my behaviour it shows what a *fool you* are."

As to why I was drinking, I don't really know. To escape from situations which I did not like and which I knew, inwardly, were of my own making. My home life, such as it was, was unhappy. My wife nagged, because she was frightened and I was practically impotent sexually. I had a continuous craving for excitement, emotional experiences, and friendships. I longed to escape from the boredom and worries of everyday life and the dissatisfaction with my job, which was in turn caused by my drinking. The more I drank the less I found what I wanted or was capable of responding to it if I found it. I was in a vicious cage, from which the only escape seemed to be drink.

Finally, to use a cinema cliché, " came the dawn." I woke one morning feeling worse than ever before. I remembered nothing. I didn't know where I was and I had no money in my pockets. I knew, not for the first time, that I was *playing* ducks and drakes with my future and was likely to lose my job at any minute. I swore I would never take another drink—but what was the use ? I had done that before. Maybe I wouldn't drink for a while, but sooner or later, at the most unlikely moment (probably) I would take the first drink. The merry-go-round would start, and I should be a passenger until such time as it chose to stop.

It was then that I sought out Alcoholics Anonymous (A.A. to its members) and learnt the two slogans which were to be—which are to be, please God—my salvation. The first is, " Never take the first drink," but the second is the more important : " I won't have a drink *today* " —not for a week, not for a month, not never, but just today.

Most alcoholics are by nature convivial. They like the fun of social intercourse, of parties, of people, and by the very nature of their disease these things lead to the indulgence in alcohol which is, to them, fatal.

How then does an alcoholic who does not drink carry on with his normal life ? I was in the habit of going to a pub or a club in the evenings. Some of my fellow members of A.A. had, I knew, given up their drinking friends, resigned from their golf clubs, cut themselves off from all their normal outlets for relaxation. They had, in general, behaved like startled hermit crabs. I made up my mind that I would do no such thing. If I did, I would inevitably start drinking again from sheer boredom, which was about the one excuse I had never used.

I continued to see my friends, drunk and sober, but I didn't drink. If my friends bored me rather, when they were drunk, it was a useful yardstick to measure how boring I must have been to them.

At first I drank tomato juice, until I found that over-indulgence in that beverage had an effect different from but almost as uncomfortable as over-indulgence in alcohol. Thereafter I varied my temperance tipples —ginger beer if it was hot ; tomato juice if it was cold ; and as a standby gin and tonic without the gin. In bars where I am known, and where the double whisky used to be set up as I came through the door, I now order a double gin and tonic. This is an accepted joke, but if I tried to get the gin into it I would find myself involved in an embarrassing explanation with the barman, who knows and approves of what I am doing.

My friends, with one or two exceptions (who are not perhaps as good friends as I thought), are delighted. I know that, even if I begged for it, I wouldn't get a drink in their houses or in their company, and I'm proud of it. I am not, as I feared, a bore ; on the contrary, I was a bore before, but didn't know it.

There are, I have discovered, worse deprivations than that of alcohol, and freedom from it brings many and unexpected benefits. I now know that what can't be cured can be endured far more easily than I had thought. For the first time in years I feel well. My hand is steady and my brain functions as it ought. I take pleasure in many activities, mental and physical, which had long been closed books to me. My home life is normal and happy.

---

* By a Member of Alcoholics Anonymous, BM/AAL, London, W.C.1.

There are, of course, moments of depression, moments of temptation—times when things go wrong and it seems that nothing but a good stiff drink will ease the situation. There always seems to be, though, another fellow who needs help over the stiles far more than I need a drink, and in helping him the moment passes.

There lies the strength of A.A. You would be a pretty poor sport if you refused to help someone because you wanted a drink yourself, and you would be a pretty good hypocrite if you had a drink first and didn't admit it. And anyway, you can't fool an alcoholic on alcohol. He knows more answers than you can think up.

I no longer say, "I will never drink again." I know that it is always possible that I may take a drink tomorrow, but I say, with ever increasing confidence, "I won't have a drink today." And so it adds up. One day without a drink added to another soon makes a week; a month. Every person helped is another prop to one's own defences, and every alcoholic reclaimed is another member of A.A., and so it goes on.

A diabetic does not voluntarily take sugar. He certainly wouldn't if he knew that having had one spoonful he would inevitably finish the bowl. Alcohol, to the alcoholic, is like that. And this is why an alcoholic can never drink. He must adjust his life rationally to his incurable disability and make the most of the great deal which is left.

Medicine and the Law

Mistaken Diagnosis of Cancer

Mr. Justice Birkett's decision in Whiteford *v.* Hunter and Gleed is disquieting to the medical profession. A 70-year-old plaintiff sued a surgeon and a general practitioner for damages on the ground of their negligence in wrongly diagnosing his condition. They had told him, he said, that he was suffering from cancer and had only nine months to live. He had thereupon given up a business in London which brought him in £1600 a year, and a company directorship worth another £150, had sold his books and furniture, and had gone off to America (his wife's native country) to die. An American surgeon had then operated upon him for a bladder complaint which he declared to be the sole and the obvious cause of his condition. This operation had established that there was no cancer and had restored him to health. The plaintiff claimed that he had suffered pecuniary loss and mental agony as a result of the defendant's mistake. The allegations of negligence by way of mistaken diagnosis were made against both defendants without distinction, but, as Mr. Justice Birkett observed during the course of the hearing, the defendants pleaded that the diagnosis was made by the surgeon (Mr. J. B. Hunter) and not by the general practitioner (Dr. S. R. Gleed) and that the latter had been acting under the former's instructions.

In the course of the hearing the judge asked the defendant's counsel if there had ever been a case in which a court had assessed damages for the mental distress of a man who had been told that he was going to die. There has, of course, been considerable discussion in legal journals of "shock" cases, including those where a mother has claimed for mental distress on seeing her child placed in danger. The defendants naturally insisted that no practitioner guarantees his opinion to the extent of insuring the consequences to the patient. Mr. Whiteford had to show that no surgeon exercising reasonable care and skill could have come to the conclusion reached by Mr. Hunter. Unless this was proved, the plaintiff failed to establish any lack of care and skill on the part of the defendants.

Mr. Justice Birkett's considered judgment, reported in the *Times* of July 30, stated that the plaintiff, when he saw Mr. Hunter, was suffering from acute urinary retention. Mr. Hunter formed the view that this was due to enlargement of the prostate; he advised immediate draining of the bladder and removal of the prostate gland later. The bladder was drained and the plaintiff subsequently attended hospital on April 5, 1942, for the operation. Mr. Hunter examined the bladder manually and visually; he found an indurated mass in the bladder about the size of the palm of a man's hand; there was no ulceration. After considering this condition for from 20 to 25 minutes, he came to the conclusion that it was a carcinoma which had not yet ulcerated, and that it was inoperable. He made no examination with a cystoscope and took no specimen of the growth for microscopic examination. In the following September, when in New York, the patient came under the care of Dr. Benjamin Barringer who examined him with a cystoscope under a spinal anæsthetic and took a sample of the growth for pathological examination. This revealed cystitis but no cancer. Dr. Barringer operated for removal of portions of the prostate gland; he found the bladder inflamed and a diverticulum filled with calcareous matter.

The learned judge held that no negligence could be attributed to Dr. Gleed. During Mr. Hunter's examination of the patient in April, Dr. Gleed had a partial view of the bladder but it was Mr. Hunter who had charge of the operation. There was no obligation upon Dr. Gleed as a general practitioner either to have or to use a cystoscope. Mr. Whiteford's action against him failed.

As regards the claim against Mr. Hunter, everything turned upon the mistaken diagnosis of inoperable cancer which determined him to do nothing more and which occasioned the patient's loss and damage. "It was," said the judge, "a virtual sentence of death." It was now admitted that the diagnosis was wrong. Mr. Hunter had done nothing afterwards to confirm or verify it. He had given evidence of his reasons for not using a cystoscope and for not making a microscopic pathological examination. There had been medical evidence of the close resemblance between true and simulated cancer. His Lordship said he was clearly of opinion that Mr. Hunter was negligent in not making the microscopic examination; he was lacking in his duty in taking no step to check or verify his diagnosis and also in not making a cystoscopic examination. Judgment was entered against Mr. Hunter for £6300—namely, £2000 general damages for the patient's pain and suffering, and £4300 for special damages claimed, such as his loss of income, his out-of-pocket expenses in departing to America, and his loss on sale of books and furniture. A stay of execution was granted with a view to appeal.

The importance of the decision is obvious. To omit to use all proper and accustomed aids to diagnosis is obviously a breach of professional duty, but Mr. Hunter had given the court his reasons for not having taken other steps. Neither specialists nor general practitioners can guarantee their opinions to be infallible. An honest error of judgment can fall far short of legal negligence. Distressing as they were to Mr. Whiteford, the mental consequences of Mr. Hunter's diagnosis (the "virtual death sentence"), though they made sensational headlines in the lay press, do not alter the principles of law. It is so easy to be wise after the event. If courts receive authoritative professional testimony that an opinion, although ultimately proved to be wrong, was neither impossible nor unreasonable at the time and in the circumstances of the particular case, nothing but overwhelming expert evidence to the contrary should justify a finding of negligence.

Public Health

Poliomyelitis

IN the week ended July 24, 39 cases were notified in England and Wales. In the weeks ended July 3, 10, and 17, notifications numbered respectively 36, 23, and 30.

Paratyphoid Fever at Eastbourne

Paratyphoid fever has been reported from Eastbourne, where up to last Monday 35 suspected cases had been found, of which 24 had been confirmed. Most of the patients are children; in all the illness began about the same time, suggesting a common source of infection. None is seriously ill.

In England Now

A Running Commentary by Peripatetic Correspondents

OUR Torch-bearer was due at the Cob Tree at 4.17 A.M., and we were lucky, because it was still dark. Much of the effect must be lost in daylight. Fred, who brought the torch 2½ miles from the next village to the pub at the bottom of our lane, is a local lad in the building trade. He qualified for this job by winning a special 8-mile race in the village sports. Why 8 miles I don't know; perhaps to allow for the 2 lb. weight of the Torch, the possibility of bad weather, and the lowered metabolism of 4 A.M. He finished the 8 miles with remarkable sangfroid, and we noticed the same on the great day, when he arrived, smiling happily, without a hair out of place, at our pub.

We had set the alarm clock for 3.50, but we were only just in time. As we came down the lane we saw a procession of car and bicycle lamps coming slowly along the main road. "It's him!" we cried, throwing grammar to the winds and breaking into a trot. It was Fred sure enough, preceded by an A.A. motor-cyclist, accompanied by bicyclists, and followed by a couple of motor coaches and a small string of private cars. There was no question which was the more out of breath—we after galloping a hundred yards downhill, or Fred after his long run.

Half the village had got up to greet him, including all those in the lower age-groups, and there was a sprinkling of strangers in cars. Everyone was talking at once, pressing round Fred, smacking him on the back, cracking jokes, demanding a light for cigarettes from the torch; one woman stood lighting them for people on the outskirts of the crowd. There was a little wait, because Fred had run his distance in under the allotted time; so all the children had a chance to hold the torch and read the inscription—"Olympia to London, with thanks to the Bearer," I think. In the end the next man emerged from one of the coaches, bald-headed and singlet-clad, with his unlit torch. While a photographer flashed his magnesium Fred formally handed on his flame, and we at last remembered to cheer when the new torch blazed up in fine style. Then, while Fred doused his torch in the saloon bar, aided by his admirers, the next man started off up the hill, and we watched his flame getting smaller among the trees until it passed round the bend. Within a couple of minutes it was light, and, like the audience emerging from a cinema, we noticed for the first time the details of our fellow-spectators; some of the aristocracy with cars were clad in variegated dressing-gowns, and there were some flowing nighties showing under overcoats.

"Well," said one of the fathers carrying a little boy on his shoulders, "if you live to be a hundred you won't see the Cob Tree open again at four in the morning."

* * *

Some years ago I noticed that one of the main differences between a specialist and a general practitioner was the thoroughness with which the specialist examined cases. Had the general practitioner been nearly as thorough, he could not have failed to have reached the correct diagnosis. There are other important points of difference, such as experience and training, but this question of thoroughness seemed to me fundamental; so I set out to become a specialist, and have now achieved that status. During the last few years I have served in the Army in various capacities, done locums in general practice, and had quite a wide experience of hospital outpatient departments, teaching and otherwise. Most of the errors I have seen committed by myself and others have been due to lack of thoroughness, but the remedy does not lie wholly in ourselves; the place where the patient is examined is also important. Proper examination is impossible in many surgeries, especially branch ones, and the conditions of work in many outpatient departments, with particular regard to noise and excessive numbers, are well known. If only many doctors had better facilities for examining patients the standard of medical practice would rise considerably. Let it be hoped that our planners will concentrate on providing conditions for thorough clinical examination before increasing the facilities for ancillary investigations such as X-ray and laboratory services, many of which might be rendered unnecessary by clinical thoroughness.

* * *

Why can't we use simple words like normal, all right, or nothing wrong, in our case-notes? It always has to be something like negative or N.A.D.—I would almost prefer O.K. Our American colleagues are even better—or worse—at this little game. The following summary may not have appeared in its entirety in any American hospital chart (case-record), but the terminology is genuine:

> This was the first gastro-enterology visit of this thirty-two-year-old married white female, looking her stated age, and in no apparent distress.
>
> *History:* She had a case of diarrhœa two weeks ago but has been asymptomatic since L.M.D. (local doctor) prescribed bismuth. Colitis of banal or ulcerative origin was suspected.
>
> *Examination:* Mouth: unremarkable. Teeth: in good repair. Pharynx: clear. Abdomen: non-contributory. Gastric analysis: physiological. X-ray work-up: no pathology. Other systems: benign.
>
> *Diagnosis:* ? Psychosomatic.
>
> ℞: Close case in gastro-enterology.
> Refer to psychiatry for opinion and treatment.

* * *

Opposite the big white modern hotel is the Savannah, a huge flat stretch, with its racecourse, playing-fields, and huge samman trees around its periphery, where the single-decked, open-sided trams run. Right across the Savannah are the Botanic Gardens. As I went in I was approached by a little Indian man, or as we call them in the West Indies, an *East* Indian. I thought I was going to be pestered to buy beaten "silver" bangles or "Luckies," but he announced himself as one of the gardeners and offered to show me round. When I told him I was a doctor he concentrated mainly on medicinal plants. I saw a large tree, with gum smelling of real friar's balsam oozing from its bark, *Myrospermum peruiferum*; a *Strychnos nux vomica* tree, with fruit the size of small oranges; a Coca plant (*Erythroxylon coca*), rather like a blackthorn bush, with vivid green tapering leaves and small red berries. "Over there," said my guide, "you get another tree that gives you dope—the kola nut. You get Coca-Cola from that." We came to a large tree with dark green foliage and big red pæony-like flowers stuck all over it. He sank his voice to a whisper: "This is the Venezuela mountain rose, most useful tree of all. You know when a woman gets a chill—the menstruation stops? Well, the flower of this tree brings it back again. One flower, one dose." I tried to look knowing too.

* * *

My daily maid turned up the other day all smiles and happiness. A long-forgotten relative in Australia had sent a food parcel, and she and her sister had enjoyed the first meal. The parcel had been badly knocked about and one cardboard box seemed to have no label. It contained a brownish powder, and since there were other packages of dried beef and the like they assumed the powder was some Australian kind of Bisto. So they sprinkled it on the dried beef and cooked it. They thought the flavour was fine. But the letter which arrived later produced nausea, anorexia, and other psychosomatic symptoms. It said they should take great care of the little brown box as Aunt Matilda had recently died and they were sending along a third share of the ashes.

* * *

I do not know where I am with my face, and my photograph is even worse. I admit to a slight myopathic *rire en travers* grafted on an acromegalic background, possibly also to a flabby fissured tongue and a touch of oxycephaly here and there; but the photograph gives me not only lid-lag, a depressed nasal bridge, and risus sardonicus, but complete baldness as well. Can one wonder therefore at my horror when I saw that I was expected to submit a photograph with my application for a recent job; can one wonder that I sent a portrait of Mr. James Mason instead; can one wonder that I was then immediately short-listed but was thrown out on the point of my oxycephalus when they saw me?

Letters to the Editor

BEDS FOR PULMONARY TUBERCULOSIS

SIR,—Dr. Bentley's article and the correspondence arising from it are most stimulating. Excluding the beds which a chest physician requires for observation and diagnostic investigations, and also the beds required for major thoracic surgery, the bed needs of two groups of patients must be clearly appreciated: those needing medical treatment, and those needing nursing care.

First there are patients who have some prospect of recovery, who require definite therapeutic procedures such as are usually carried out by physicians, and who ought to receive such treatment more or less as soon as a diagnosis of phthisis is established. The treatment of such cases often need not occupy a sanatorium or hospital bed for longer than about three months at a time, since many can follow a regimen of protracted rest in their own home, if they have learned the principles of bed rest in hospital.

During the last three years, in this town with a population of 110,000, and a tuberculosis death-rate of 60–70 per 100,000, the effective number of beds at my disposal has varied from about 15 to 25, and discrimination has been needed to use them to best advantage. It has been my policy to see that first and foremost, cases requiring medical treatment as distinct from nursing care do not forgo this on account of the nursing shortage; and therefore a candidate for collapse measures has always been admitted as soon as possible, to the exclusion of less hopeful more advanced cases. During the last couple of years such patients have been admitted after an average delay of a fortnight on the waiting-list.

The justification for this policy is illustrated by the short-term-sputum-conversion-rate of the 95 sputum-positive cases diagnosed in 1947: 22 of these patients were dead by the end of the year, and it is reasonable to assume that treatment would have been of little benefit to them. Of the remainder, however, by June, 1948, 40 had had appropriate collapse measures, sputum conversion being attained in 32 instances—i.e., 30% of the total infectious cases had become "safe" within a year. Their ultimate fate is undetermined, but suffice it for the present argument that their period of infectivity has been reduced and their prospects of recovery unhampered by delay in treatment.

What of the poignant cases left among their families? These are a great source of heartache and distress to all who seek to help them; but can the physician be blamed who avoids blocking beds with such cases? With inadequate facilities it is all the more important to make optimum use of such beds as remain. On humane grounds I admit that one occasionally has to relieve the home situation by admitting such a patient. Without debating the importance of segregation, I would argue, as many others have done, that if a bed can be used to achieve sputum conversion in several patients as against the segregation of one patient, there can be no question as to its more effective use.

Let us treat the treatable cases as speedily as possible in institutions, and arrange protracted spells of rest at the patient's home. Let institutional facilities aim at attaining sputum conversion as the immediate objective. Such a programme is scarcely practicable if waiting-lists are handled by a central administration, or even by the superintendent of an institution. The closest collaboration between the chest physician, who knows the waiting patient, and the superintendent, who knows his bed limitations, is necessary.

For less favourable cases, let everything possible be done to help the family with the care of the patient, by home domestic help, district nursing, boarding-out of children, and financial aid in every possible way; but let us not be misguided by our natural sympathy for these patients into allowing their nursing requirements to jeopardise another patient's prospects of recovery.

W. H. TATTERSALL
Chest Physician.

Chest Clinic, Reading.

OPERATIONS FOR HERNIA

SIR,—In his letter published in your issue of July 17, Professor Pannett raised a point of great interest to those who are concerned with the repair of large hernias. He suggests that unabsorbable sutures are of value in these repairs not because they remain unabsorbed but because they interfere less than catgut with the processes of repair.

There is little doubt that this is the case, but there is another aspect of the subject which should be brought to your notice: the ability of a lattice of unabsorbable material, anchored to healthy tissue at many points, to prevent stretching of young fibrous tissue. The distraction strains to which a recent hernial repair is submitted can thus be distributed diffusely over many different points; the amount of strain to which any individual point is subjected is thereby much reduced. No doubt eventually fibrous tissue will contribute the chief strength to the repair, but there is a good case for providing some form of inextensible support during the critical first six months.

Edinburgh. D. M. DOUGLAS.

SIR,—In his letter Professor Pannett made some adverse comments on a point of theory I advanced in the article on July 10 on the treatment of hernia by a darn of nylon.

I agree with Professor Pannett's generalisations on tissue repair, and also with the common observation that tight sutures cut through the tissues by pressure necrosis. Should he care to try the nylon darn type of repair I suggest he be sure to place the sutures without tension but with no slackness, to make them numerous, and to anchor them to sound surrounding tissues. The effect of this is to distribute a strong strain, when it comes, to many points and to curb it, as Gulliver was held by the threads of the Lilliputians. Unlike the continuous pressure of a tight suture, that of a suture in a darn is intermittent and the tissues do not necessarily undergo a process of necrosis in such circumstances. The same contrast is seen, on the one hand in a plaster sore due to continuous pressure, and on the other in the survival from intermittent pressure of the skin tube in a cineplastic amputation.

Professor Pannett's point about the tissues being alive is also commonly observed. Some fibrous reaction is bound to occur where and when they take strain. This fibrous tissue and the block of it formed to fill the mesh of the darn will deal adequately with many strains, but I believe that the darn itself is the factor which enables high strains of short duration to be contained successfully, repeatedly, and permanently. Fibrous tissue alone is fickle and liable to tear if not reinforced by a darn into structures strong enough to take high strain. Thus sepsis in catgut or fascial darns provides ample amounts of laudable fibrous tissue, but such cases are prone to early and late recurrence.

Though Professor Pannett finds the theory unacceptable, I hope he will condone it if he should try the nylon darn technique and find it giving satisfactory results.

Oxford. G. E. MOLONEY.

MEDICAL RECORDS

SIR,—The attention which some lay officers in hospitals are giving to the care of medical records is bringing to light difficulties that are removable. At a recent tuition course of the Hospital Record Officers Association held in Manchester the difficulty of finding a good medical stenographer was acknowledged. On the other hand, the stenographer's work would be aided, and the standard thereby improved, if the medical staff, and especially the younger generation, could dictate with fair ability. The basis of a good medical report is a thorough grasp of the information to be conveyed in it, and the capacity to express this in clear English. Medical records would certainly benefit if medical students were disciplined, as proposed by the B.M.A. medical curriculum committee, "in the proper meaning and use of words and the relationship of names and words to ideas and things."[1] The discussions during the course provided evidence that the absence of this ability has to be made good by the medical record officers. This dependence upon the lay staff, while testifying to their zeal and efficiency, seems in some cases to have reached a point where the main responsibility for the accuracy of records is placed upon the layman. In these medical record officers the medical staff may find valuable auxiliaries, but nothing will be gained by a confusion of functions. Distasteful as paper work may often be to the medical man, these records provide essential material for medical education and the efficient working of the National Health Service.

OBSERVER.

CHARMS

SIR,—One can but wholeheartedly agree with Dr. Dillon that psychology on a scientific basis ought to be our ideal, and we must all share fully his aversion to procedures resembling—or imitating—the methods of superstition. But we must admit the "metaphysical" aspect of the human personality: that is, the deep-rooted desire for the belief in the supernatural and unexplainable, for the ceremonial and magical. Whether we like this aspect of personality, or deplore it as atavism and superstition, we cannot afford to ignore it. In some people an approach on these lines—whether in the cause *of morality or health—promises better and* speedier results than the employment of logical and scientific concepts. In most people, indeed, this "metaphysical" aspect is strong, and may be stronger than the capacity for the "intelligible"; and in these the psychosomatic function responds better to magical than to scientific approaches. This has been abundantly illustrated by the appeal—and even therapeutic efficiency —of sacred wells, spiritual healings, and the less dignified activities of various quacks and therapeutic eccentrics. If we wish to be sincere we cannot ignore the large number of cures, where scientific medicine had previously failed, by these healers and methods. As a psychiatrist with twenty years' experience I find more people fit for magical methods than for modern psychotherapy. We may regret that this is so, especially since we average psychiatrists cannot perform such miracles; our training has made us unfit to use them, and our reputation as "scientific psychiatrists" inhibits the patient's belief in our magical powers. But I doubt whether any real harm is done by practitioners who feel able to apply them in selected cases. People helped by such primitive means may be more superstitious than intellectual, but they are not necessarily less happy or less reliable and humane. It is unlikely that pure science and logic will ever dominate human and social life. While regretting this, we must be content to fight prejudice and superstition where it is obviously antisocial, and tacitly accept the "metaphysical" aspect of the human personality where it brings advantages. I hope Dr. Dillon will forgive my spirit of compromise.

Harley Street, W.1. S. LOWY.

ATOMIC DEFENCE

SIR,—Your admirable summing up, on July 24, of the implications of accepting the inevitability of atomic warfare constitutes a challenge to medical men which is both urgent and grave.

It is clear that unless there is firm determination to grasp the opportunities which still exist to ensure the peace, we must abandon all our cherished hopes and plans for improving the health and wellbeing of the nation; for once we allow ourselves to accept the idea of war, all our energies must be bent to making what provision we can to limit the effects of the disaster. How little can be achieved by way of medical relief for the victims of atomic warfare, and at what enormous cost in organisation, manpower, and material, is clearly to be seen from the articles you quote.

But the choice which confronts us is not one between "making defence henceforward the chief end and aim of our existence" and neglect of the necessary measures of defence. Mercifully, the choice still lies between the path to war and a return to the path of peace. So long as such a choice exists—and time is short—surely the answer of our profession must be to take our stand for peace.

Pontyclun, Glam. JOHN B. ATKINS.

M.R.C.P. EXAMINATION

SIR,—I think the time has come for the Royal College of Physicians to devise a method of assessing the clinical acumen of candidates for the M.R.C.P. in some better and fairer way than at present. Everybody is aware that the "luck of the case" is practically 70% of the examination. There is an element of luck in every examination; and surely a time will soon come when examinations will be superseded by some other method of testing. Till then examinations are necessary.

In the membership examination the cases shown are varied in type. Some are quite simple, and some are made very simple by the kindliness of the patient; but others are complicated and bristle with difficulties, especially when the time allotted is hardly sufficient to take a history, examine all the systems, and do the necessary urine tests. No candidate sitting this examination will ever grudge getting a difficult case, but he will certainly have a grudge when his friend, who is perhaps *only* half prepared for the examination, gets away with it merely because of the simplicity of his cases or because he has heard about the cases from someone who has been asked to examine them the day before. The cases are often repeated from day to day and from examination to examination, though perhaps there is no remedy to this. But then why attach such importance to this qualification?

I suggest some better method of clinical testing should be devised. If the final pass percentage is 16%, about 60% of the candidates should be weeded out by stiff papers which should be corrected before the clinical examination; and the balance of 30% (which will amount to 180 if 600 enter) should be given a very searching clinical test. Several cases should be shown, and the censors should watch how the candidates tackle the cases. Of course, the same number of examiners and hospitals as at present should be utilised to enable this type of clinical examination to be conducted. The pruning to the required percentage could be done in this and the next two rounds.

M.R.C.P.

MOVEMENT OF THE DIAPHRAGM AFTER OPERATION

SIR,—Mr. Howkins says in his Hunterian lecture, published in your issue of July 17, that postoperative diaphragmatic inhibition does not necessarily occur on the same side as the abdominal incision, as found by Rees Jones.

An investigation which is now proceeding, tends to show that the postoperative pulmonary changes occur on the same side as the subdiaphragmatic air-bubble. The changes are usually most pronounced where the quantity of intraperitoneal air is large. The right hemidiaphragm being higher than the left is a reason for the air to collect on the right. Added to this, of course, is the fact that the majority of incisions are on the right. In midline gynæcological incisions the intraperitoneal air appears to be held under the omentum and in many cases does not reach the subdiaphragmatic area.

It is unfortunate that Mr. Howkins's X-ray plates have not been reproduced more clearly.

Charing Cross Hospital, London. ANGUS SMITH
Hon. Anæsthetist.

A TAX ON KNOWLEDGE

SIR,—I noted with interest the leading article in your issue of July 10. I have been carrying on a correspondence with the Departmental Claims Branch on this subject since April, though I am still not clear on some points.

I find that the British Medical Association library is unable to supply quite a proportion of the original literature that I require, and I wished to apply for fellowship of the Royal Society of Medicine. I did not consider, however, that I could really afford yet another subscription, and I therefore inquired as to the possibility of claiming for this and various other subscriptions—e.g., to *The Lancet, British Medical Journal*, and Lewis's Library. Mr. Justice Rowlatt's judgment makes it clear that these are not admissible under the present wording of Schedule E. From the wording of Schedule D, however, I take it that they are admissible for civilian practitioners. This is surely an unjustifiable anomaly and one which every effort should be made to alter. Although it is not essential to subscribe to various journals in order to obtain or retain one's commission, it *is* essential to subscribe in order to keep reasonably up to date, which any self-respecting doctor must do. Moreover, in many appointments in the Services, as in my present one, there is comparative professional isolation, the stimulating effect of discussion with colleagues is sadly missed, and it is more than ever necessary to attempt to redress the balance with additional reading.

I hope that you will not allow this matter to rest.

SURGEON LIEUTENANT.

CARS FOR DOCTORS

SIR,—The present unsatisfactory situation in respect of doctors' cars can well be illustrated by my own case.

To save myself five hours' daily in buses, I bought a pre-war car early this summer at an inflated price, having had it expertly examined first. However, it is an old car and the parts are inevitably worn; so far I have had to replace the crown wheel and pinion, the front springs, and the battery, as well as many smaller repairs over three months. It is more than I can afford, but there is no alternative.

I live in a wealthy area where new cars are commoner on the roads than old ones, and I often wonder how the priority system makes this possible. The other day I went to view another second-hand car which the owner was selling, having just acquired a new Austin A 40 Devon Saloon—the very car I have on order with a B.M.A. priority. The man explained that he had no priority, being an ordinary business-man, but that he had waited "a long time—over 18 months."

INDIGNANT.

EMETINE FOR VARIOUS INFECTIONS

SIR,—Emetine has long been known as an effective agent for amœbic abscess of the liver. It has also been used for pulmonary abscesses; and where improvement has been achieved, this has been accepted as proof of an amœbic origin. But I found that emetine can also be very effective against non-amœbic liver abscesses, and this led me to try it against many other septic infections. My results, of which only a small part has hitherto been published,[1] have been very satisfactory and often rather surprising.

In each of 9 cases of virulent furuncle of the lip, most of them very severe, which were treated with emetine, prompt recovery ensued. In 4 cases of traumatic purulent meningitis the cerebrospinal fluid became sterile after a few days' treatment; 3 cases were definitely cured, while 1 died six weeks afterwards in consequence of a brain abscess. All of 20 cases of severe biliary infection responded to emetine; in some no other treatment was used, while in others surgical treatment had been undertaken and had proved insufficient. In many cases of severe purulent peritonitis (mostly of appendicular or traumatic origin) and of gaseous gangrene, and in some cases of brain abscess, very good results were obtained.

Emetine is sometimes highly effective against infections due to penicillin-resistant organisms—notably, *Bact. coli* and *Pseudomonas pyocyanea*—particularly where penicillin cannot be applied directly or when its action is impeded by thick abscess membrane or much necrotic tissue.[2]

With infected mice Bernoulli[3] has experimentally confirmed my clinical results. Of 10 animals infected with *Staphylococcus aureus* and treated with emetine, 6 were still alive ten days afterwards, whereas of the untreated animals none survived more than five days. In vitro the bactericidal action of emetine was observed to be slight, but the bacteriostatic action was long-continued. Fischer and Almasy[4] have lately studied the effect of emetine on the metabolism of *Oidium albicans*. Further experimental and clinical investigations are desirable.

NEGOTIATING BODY FOR PUBLIC-HEALTH MEDICAL OFFICERS

SIR,—I refer to the advertisement in your is of July 24 in connexion with the appointment of medi officer of health for the county borough of Read' It states that the appointment is subject to the conditi of service promulgated by the National Joint Coun for Local Authorities' Administrative, Profession Technical, and Clerical Services. This gives t impression that the National Joint Council, which is t negotiating machinery for certain categories of loc government officer, includes local-authority medi officers within its purview. This is not so, and I sho be glad if you would permit me, through your colum to correct any such impression which may have form in the minds of your readers. The British Medic Association is recognised by the Ministry of Health a the Associations of Local Authorities as the negotiati body for public-health medical officers, and until the ne salary scales and conditions of service are negotiated, t Askwith Memorandum, as revised, is the only agreeme which applies to medical officers.

Furthermore, the Association is not represented the National Joint Council and was not consulted in t formulation of the latter's scheme.

British Medical Association,
Tavistock Square, London, W.C.1.

CHARLES HILL
Secretary.

*** We published the advertisement, without omi sions, so that possible applicants should be aware the attitude of the Reading corporation. Dr. Hill i of course, entirely right in holding that conditions o service for doctors in public health, as in other branche of the National Health Service, should be negotiat with representative medical organisations. So far a the medical profession is concerned, conditions of servic promulgated by the National Joint Council have n validity.—ED. L.

AN OBSTETRIC EMERGENCY SERVICE

SIR,—It is with particular interest and pleasure th I have read your article (July 24) on the Ayrshi Emergency Domiciliary Service.

Mention is made in it of the attempt to replace th amount of blood or plasma transfused by encouragin the relatives of recipients to donate blood. This schem has been developed by Dr. de Soldenhoff, not only i the emergency service, but in his hospital work at th Ayrshire Central Hospital, Irvine. During the pa nine months Ayrshire Central Hospital has used bloo and plasma equivalent to 325 blood donations; in th same period 182 donations have been made under th replacement scheme, representing 56% replacement.

This work has been carried out by the medical an nursing staff of a busy obstetric hospital, and reflec great credit on all concerned. It shows how muc can be achieved in replacing blood used; and th scheme might well be developed in all large hospital Such contributions are of great value to the region transfusion service, not only by keeping the blood ban adequately stocked, but also by showing how much th hospital appreciates any help which is given by th transfusion service.

DOROTHY NELSON
Organising Secretary, Glasgow and West of Scotland Blood Transfusion Service.

15, North Portland Street,
Glasgow, C.1.

DAME AGNES HUNT

IN supplement to our annotation last week J. M. writes: "Dame Agnes Hunt wrote a delightful litt book called *This is My Life* in which she records her ow victory over pain and recurring disability, and th steps that led up to the founding of Baschurch Home i 1900. This brave story, which appeared in 1938, oug to be republished, 'No splendid vision prompted th open-air hospital,' she says with simple truth; and thes words serve to remind us of her two greatest qualitie The first was genius for improvisation. Agnes Hu did not bother much about the distant scene, but sh knew with unerring intuition the next step. Th cond was her remarkable technical skill in nursing, devising apparatus, and in doing what was necessary make the patient well. She has taken a leading part the advance of non-operative orthopædics. In addi-on, she felt the inly touch of love for cripples and she ew how to make them happy."

Parliament

Rural Water-supplies

In the House of Commons on July 27 Mr. JOHN DWARDS, parliamentary secretary to the Ministry of ealth, said that the Government would have to consider hat further provision for rural water-supplies should made when the £15 million voted for grants in 1944 as exhausted. He did not think that it would prove iough. The Government had put forward a great fort to improve rural water-supplies, and local thorities had been encouraged to submit schemes, d the estimated cost of such proposals submitted to ie Ministry exceeded £35 million. Permission for ork to start had been given to schemes costing about 5 million. In addition, schemes to a total of about 3 million had been approved in principle, and the overnment had promised grants under the 1944 Act r schemes costing nearly £9 million.

Parliament adjourned on July 30 for the summer cess until Sept. 13.

The Royal Assent was given to the Veterinary Surgeons ct, the Nurseries and Child-minders Regulation Act, he Factories Act, the Criminal Justice Act, and the tatute Law Revision Act.

QUESTION TIME

Hospital Accommodation for Private Patients

Mr. G. M. SHARP asked the Minister of Health what structions he had given to regional hospital boards about he amount of hospital accommodation which might be served for doctors' private patients; who decided to which atients this should be allocated; how the charges made ould be determined; and for what purposes the receipts ould be used.—Mr. ANEURIN BEVAN replied: As an interim neasure, I have approved the continued use for this purpose f any accommodation so used immediately before the ppointed day until regional boards can review the position nd draw up considered proposals. The hospital manage-ment committee concerned is responsible for the admission rrangements. Hospital charges will be determined by that ommittee in accordance with the National Health Service Pay-bed Accommodation in Hospitals, &c.) Regulations,[1] hich also prescribe maximum fees recoverable by the medical ractitioner for professional services. The receipts from ospital charges will be paid into the Exchequer.

Employment of Assistants under N.H.S.

Sir ERNEST GRAHAM-LITTLE asked the Minister whether e was aware of hardship to many doctors resulting from the hange-over in health services; and whether he would make an interim regulation allowing those doctors who had employed assistants for a minimum period of six months prior to July 5 to continue to employ them as of right for a further period of six months under the terms set out in the Minister's circular dealing with the remuneration of general practitioners.—Mr. BEVAN replied: Executive councils have been asked to consent without question to the continued employment in the National Health Service of assistants employed before the appointed day. The remuneration of such assistants is a matter for their principals. The arrangements for grants for training assistants without previous experience are under discussion with the profession.

Excessive Prescribing

Mr. H. E. RANDALL asked the Minister of Health if he was aware that the regulations issued in connexion with the National Health Service concerning the procedure to be adopted for he investigation of excessive prescribing had created considerable feeling among the medical profession, and whether he ould give an assurance that, whilst such procedure might e necessary to prevent extravagance, it would not be used to estrict the doctors.—Mr. BEVAN replied: This procedure is on similar lines to that which has been in operation for many years under the old National Health Insurance Scheme. It is aimed exclusively at extravagant prescribing and will certainly not be used to restrict any prescribing necessary for the treatment of the patient.

Sir THOMAS MOORE asked the Minister what authority had been delegated to local medical committees to prevent a medical practitioner from prescribing any drug or medicine which he considered necessary for the treatment of an insured patient.—Mr. BEVAN replied: I should like it to be quite clear that patients are entitled to all drugs necessary for their proper treatment. Local medical committees have only power to investigate excessive prescribing.

Remuneration of Junior Specialists

Sir ERNEST GRAHAM-LITTLE asked the Minister whether he was aware that a large class of younger specialists, including holders of grants under the various grades of the health scheme, had not been offered even interim contracts under the Act, and that they were receiving approximately half the salary which they might expect from the Spens report recommendations, and as many of them, as in an example submitted, had been qualified 10 years, were married, had families and were suffering from financial strain, whether he would give an assurance to them that the adjustments would be retrospective and would be made quickly.—Mr. BEVAN replied: No interim contracts are necessary where, as was usual, holders of junior hospital appointments immediately before July 5 were whole-time officers, because they passed as transferred officers automatically into the employment of the appropriate hospital management committee or board of governors. Any adjustment of their present remuneration (which, I am aware, is often less than that recommended by the Spens Committee) must await the drawing up of agreed rates with the profession, as in the case of specialists; as soon as agreed rates are evolved I shall do my best to see that retrospective adjustments from July 5 are carried out quickly.

Distribution of Hearing-aids

Mr. ELLIS SMITH asked the Minister when the Medresco hearing-aid would be available for all who required it; and if he would give an assurance that supplies, as they became available, would be distributed evenly between all industrial centres.—Mr. BEVAN replied: I cannot foretell the exact date on which every patient who would benefit from a hearing-aid will be able to obtain one. The number of distribution centres will, however, as the supply position improves, be steadily increased until there is one reasonably accessible in every part of the country.

Lieut.-Colonel MARCUS LIPTON asked how many of the Government's deaf-aid appliances had been manufactured and issued.—Mr. BEVAN replied: 1680 Medresco aids had been delivered from the manufacturers up to July 26, and 1200 had been issued in hospitals in England and Wales.

Spa Treatment

Sir WALDRON SMITHERS asked the Minister of Health if, in view of the resignation of Dr. Mackenna of Droitwich, he would make a statement as to spa treatment under National Health Service.—Mr. BEVAN replied: I think the doctor may have been under a misapprehension. For patients of the appropriate hospitals in the National Health Service requiring treatment of the spa type, it is open to a regional hospital board to arrange for convenient facilities for this treatment to be used, at the discretion of the medical staff of the hospital, to supplement the hospital's own resources. It is not a responsibility of the hospital service to provide treatment at spa establishments otherwise than in this way.

Financial Interest in Patent Medicines

Mr. PETER FREEMAN asked the Minister whether his regulations allowed doctors or dentists employed in the National Health Service to hold financial interests in patent medicines or other proprietary articles of a medical nature.—Mr. BEVAN replied: There is no power in the National Health Service Act to make regulations on this point.

Hearing-aids

Sir ROBERT YOUNG asked the Minister whether, during the shortage of supply of hearing-aids to those prescribed them, there would be any system of priority laid down for men and women employed in essential industries when their impairment would cause an otherwise unnecessary withdrawal of practitioners. This is surely an unjustifiable anomaly and one which every effort should be made to alter. Although it is not essential to subscribe to various journals in order to obtain or retain one's commission, it *is* essential to subscribe in order to keep reasonably *up to date, which any self-respecting doctor must do.* Moreover, in many appointments in the Services, as in my present one, there is comparative professional isolation, the stimulating effect of discussion with colleagues is sadly missed, and it is more than ever necessary to attempt to redress the balance with additional reading.

---

[1] *Lancet*, July 31, p. 193.

I hope that you will not allow this matter to rest.

SURGEON LIEUTENANT.

CARS FOR DOCTORS

SIR,—The present unsatisfactory situation in respect of doctors' cars can well be illustrated by my own case.

To save myself five hours' daily in buses, I bought a pre-war car early this summer at an inflated price, having had it expertly examined first. However, it is an old car and the parts are inevitably worn; so far I have had to replace the crown wheel and pinion, the front springs, and the battery, as well as many smaller repairs over three months. It is more than I can afford, but there is no alternative.

I *live in a wealthy area where new cars are commoner on* the roads than old ones, and I often wonder how the priority system makes this possible. The other day I went to view another second-hand car which the owner was selling, having just acquired a new Austin A 40 Devon Saloon—the very car I have on order with a B.M.A. priority. The man explained that he had no priority, being an ordinary businessman, but that he had waited "a long time—over 18 months."

INDIGNANT.

EMETINE FOR VARIOUS INFECTIONS

SIR,—Emetine has long been known as an effective agent for amœbic abscess of the liver. It has also been used for pulmonary abscesses; and where improvement has been achieved, this has been accepted as proof of an amœbic origin. But I found that emetine can also be very effective against non-amœbic liver abscesses, and this led me to try it against many other septic infections. My results, of which only a small part has hitherto been published,[1] have been very satisfactory and often rather surprising.

In each of 9 cases of virulent furuncle of the lip, most of them very severe, which were treated with emetine, prompt recovery ensued. In 4 cases of traumatic purulent meningitis the cerebrospinal fluid became sterile after a few days' treatment; 3 cases were definitely cured, while 1 died six weeks afterwards in consequence of a brain abscess. All of 20 cases of severe biliary infection responded to emetine; in some no other treatment was used, while in others surgical treatment had been undertaken and had proved insufficient. In many cases of severe purulent peritonitis (mostly of appendicular or traumatic origin) and of gaseous gangrene, and in some cases of brain abscess, very good results were obtained.

Emetine is sometimes highly effective against infections due to penicillin-resistant organisms—notably, *Bact. coli* and *Pseudomonas pyocyanea*—particularly where penicillin cannot be applied directly or when its action is impeded by thick abscess membrane or much necrotic tissue.[2]

With infected mice Bernoulli[3] has experimentally confirmed my clinical results. Of 10 animals infected with *Staphylococcus aureus* and treated with emetine, 6 were still alive ten days afterwards, whereas of the untreated animals none survived more than five days. In vitro the bactericidal action of emetine was observed to be slight, but the bacteriostatic action was long-continued. Fischer and Almasy[4] have lately studied the effect of emetine on the metabolism of *Oidium albicans*. Further experimental and clinical investigations are desirable.

Notes and News

REPRESENTATION OF SPECIALISTS

A CONFERENCE of representatives of the Royal Colleges, two of the Royal Scottish Corporations, and the British Medical Association was held at the Royal College of Surgeons on July 28, to discuss the general question of the organisation to represent consultants in the future. Sir Lionel Whitby, president of the British Medical Association, presided. After discussion it was decided to submit to the bodies invited to the conference the following propositions:

(i) That a Joint Committee of the Royal Colleges, the Royal Scottish Corporations and the British Medical Association be established to advise the Minister of Health on all matters concerning consultants and specialists.

(ii) That the existing Committee of the Colleges and Corporations, and the Central Consultants and Specialists Committee established by the British Medical Association, continue in existence to brief the Joint Committee.

(iii) That the Joint Committee be requested to allocate, as soon as practicable, fields in which their constituent bodies are free to take independent action and to deal with governmental bodies direct.

It was agreed to establish an exploratory committee of nine members with Sir Lionel Whitby as chairman.

University of Oxford

At a convocation on July 21, the honorary degree of D.C.L. was conferred on Sir Arcot Lakshmanaswami Mudaliar, F.R.C.O.G., vice-chancellor of the University of Madras.

Dr. D. S. Hayton-Williams has passed the examination for B.A. (honours jurisprudence).

University of Cambridge

On July 26 a doctorate of law was conferred on Dr. T. B. Davie, who has lately been appointed vice-chancellor of the University of Cape Town.

The Copeman medal for medical or biological research has been awarded to Dr. David Vérel.

University of London

Dr. E. P. Sharpey-Schafer has been appointed to the chair of medicine at St. Thomas's Hospital medical school, from Oct. 1.

Mr. D. S. Bertram, PH.D., has been appointed to the readership in entomology at the London School of Hygiene and Tropical Medicine, and Mr. F. L. Warren, D.SC., to the readership in biochemistry at University College.

The title of professor emeritus has been conferred on Dr. A. B. Appleton and Dr. O. L. V. de Wesselow, on their retirement from the chairs of anatomy and medicine at St. Thomas's Hospital medical school; on Dr. D. T. Harris on his retirement from the chair of physiology at the London Hospital medical college; and on Dr. T. Baillie Johnston on his retirement from the chair of anatomy at Guy's Hospital medical school.

University of St. Andrews

Dr. R. B. Hunter has been appointed to the chair of materia medica in succession to Prof. F. J. Charteris.

Dr. Hunter graduated M.B. in 1938 at Edinburgh University, where he was president of the Royal Medical Society. Later he held house-appointments and a clinical tutorship at the Edinburgh Royal Infirmary. During the war, while serving in the R.A.M.C. with the rank of major, he acted as personal physician to Field-Marshal Montgomery; and he was appointed M.B.E. Since his return to Edinburgh he has become lecturer in therapeutics in the university and assistant director of the Edinburgh Post-Graduate Board for Medicine. He has published papers on the clinical use of anti-histamine substances.

Royal College of Physicians of London

At a comitia held on July 29, with Lord Moran, the president, in the chair, the following fellows were elected officers for the ensuing year:

Censors: Dr. Donald Hunter, Prof. J. Crighton Bramwell, Dr. J. Forest Smith, Prof. R. V. Christie. *Treasurer:* Prof. W. G. Barnard. *Registrar:* Dr. H. E. A. Boldero. *Harveian Librarian:* Dr. Archibald Gilpin. *Assistant Registrar:* Dr. W. D. W. Brooks. *Members of the library committee:* Dr. Macdonald Critchley, Dr. J. Bishop Harman, Dr. M. L. Rosenheim, Dr. R. R. Bomford. *Finance committee:* Dr. J. St. C. Elkington, Dr. G. B. Mitchell-Heggs, Dr. C. T. Potter.

The following were elected examiners:

Chemistry: Mr. Alexander Lawson, PH.D., Mr. John Lowndes, F.I.C. *Physics:* Mr. Stanley Rowlands, PH.D., Mr. J. E. Roberts, PH.D. *Materia medica and pharmacology:* Prof. E. J. Wayne, Dr. E. F. Scowen, Dr. Wilfred Oakley, Dr. J. Bishop Harman, Prof. A. C. Frazer, Dr. V. J. Woolley. *Physiology:* Prof. W. R. Spurrell, Prof. J. L. D'Silva. *Anatomy:* Prof. Thomas Nicol. *Pathology:* Prof. R. J. Pulvertaft, Dr. Archibald Gilpin, Prof. W. D. Newcomb, Dr. Kenneth Robson. *Medical anatomy and principles and practice of medicine:* Dr. A. H. Douthwaite, Dr. L. B. Cole, Dr. J. L. Livingstone, Dr. K. Shirley Smith, C. B. Levick, Dr. T. C. Hunt, Dr. Robert Coope, Dr. H. L. Marriott, Dr. Horace Evans, Dr. J. C. Hawksley, Dr. F. P. Lee Lander, Dr. William Brockbank. *Midwifery and diseases peculiar to women:* Mr. D. H. Macleod, Mr. H. L. Shepherd, Mr. R. A. Brews, Mr. J. E. Stacey, Mr. G. F. Gibberd. *Public health:* part I, Prof. J. M. Mackintosh, Prof. M. E. Delafield; part II, Dr. John Greenwood Wilson. *Tropical medicine:* section A, Major-General Sir Alexander Biggam; section B, Dr. George Macdonald. *Ophthalmic medicine and surgery:* Dr. E. A. Blake Pritchard. *Psychological medicine:* part I, Dr. W. D. Nicol; part II, Prof. P. C. P. Cloake, Dr. Noel Harris. *Laryngology and otology:* Mr. M. L. Formby. *Medical radiology:* Prof. Gilbert Stead, D.SC., Dr. Peter Kerley, Prof. D. W. Smithers. *Anaesthetics:* Dr. Kenneth Robson, Dr. C. A. Keele, Dr. A. D. Marston, Dr. B. R. M. Johnson. *Child health:* Dr. Kenneth Tallerman, Dr. A. G. Watkins. *Physical medicine:* part I, Dr. J. W. Litchfield, Prof. W. V. Mayneord, D.SC.; part II, Dr. W. S. C. Copeman, Dr. D. C. Shields. *Industrial health:* part I, Dr. J. A. Charles; part II, Prof. R. E. Lane.

The following lecturers were appointed:

Dr. Geoffrey Marshall (Harveian orator), Dr. J. G. Scadding (Bradshaw), Dr. A. P. Thomson (Lumleian), Dr. C. Gavey (Goulstonian), Prof. H. P. Himsworth (Oliver-Sharpey), Dr. N. B. Capon (Charles West), Dr. J. H. Sheldon (F. E. Williams), Dr. Donald Hunter (Ernestine Henry)—all for 1949; and Dr. A. E. Clark-Kennedy (Croonian) for 1950.

The Murchison scholarship, held this year in London, was awarded to Dr. Mary Holt. The Moxon medal was awarded to Dr. N. Hamilton Fairley, F.R.S., for his work on blood-pigments and malaria, and the Weber-Parkes prize to Dr. S. Roodhouse Gloyne for his work on the morbid anatomy of pulmonary tuberculosis and its differentiation from diseases due to dust.

The following, having satisfied the censors' board, were elected to the membership:

Z. H. Abdeen, M.B. Cairo, J. C. L. Adams, M.B. Lond., A. K. S. Ahmed, M.B. Calcutta, Andrew Allison, M.B. Glasg., R. P. Aronson, M.B. Lond., D. V. Bates, M.B. Camb., J. M. Beare, M.D. Belf., T. P. Blanshard, M.D. Lond., A. W. Branwood, M.D. Edin., F. S. W. Brimblecombe, M.B. Lond., K. P. Brown, M.B. Lond., major R.A.M.C., G. N. Chandler, B.M. Oxfd, M. V. Chari, M.B. Rangoon, E. K. Cruickshank, M.B. Aberd., Marc Daniels, M.D. Paris, Stanley Davis, M.B. Lond., flight-lieutenant R.A.F., G. K. Dhariwal, M.B. Punjab, R. S. Duff, M.B. Glasg., P. R. Duncan, M.B. Manc., J. H. Brist., Robert Wigglesworth, M.B. Lond., O. G. Williams, M.B. Lond., R. B. N. Wilsdon, M.B. Lond., S. R. Wood, M.B. Birm.

Licences to practise and diplomas were conferred on those named in the reports of the Royal College of Surgeons below and in our issues of July 17 (p. 128) and June 18 (p. 971).

Register of Orthoptists

The 1948 edition of this register, published by the Board of Registration of Medical Auxiliaries, is now obtainable, without charge, from the registrar of the board, Tavistock House North, Tavistock Square, London, W.C.1.

their labour.—Mr. BEVAN replied : Otologists are being asked *to give priority to the most deaf patients and those who are* seriously handicapped in their work for lack of an aid.

Venereal Disease

Mr. R. W. SORENSEN asked the Minister of Health why the statutory protection of secrecy had been withdrawn from persons attending V.D. clinics under the new National Health Service Act.—Mr. BEVAN replied : The withdrawal results from the revoking of the Public Health (Venereal Diseases) Regulations now that responsibility is transferred to regional hospital boards. But I would emphasise that treatment for venereal disease will continue to be as confidential as it always has been.

Supplies of T.T. Milk

Mr. PHILIP PIRATIN asked the Minister of Food to what extent tuberculin-tested milk not bottled by the farmer was subsequently kept separate by the bottles and sold as T.T. ; and what steps he took to ensure that such milk was not mixed with non-T.T. milk.—Dr. EDITH SUMMERSKILL replied : In May, 1948, approximately 27% of the T.T. milk sold by producer-wholesalers in England and Wales was retailed as such. Under the Milk (Special Designations) Regulations T.T. milk sold as such must be kept separate from all other milk and sold to the consumer in sealed containers specially labelled and fitted with overlapping caps. Failure to comply with these conditions may involve dairymen in the revocation or suspension of their licences to sell T.T. milk.

Mr. PIRATIN : Is it not the case that a certain amount of T.T milk is not sold as T.T. milk at all, and is therefore wasted so far as the quality is concerned, since it is mixed with ordinary milk before being sold ? T.T. milk should be sold as such, because there is a wide demand for it.—Dr. SUMMERSKILL : Unfortunately the hon. gentleman is wrong. I wish there were a wide demand for it. Only 27% is sold as T.T. milk. We cannot govern consumer preference.

Hygiene in the Food Trades

Dr. SANTO JEGER asked the Minister of Food if he had considered the reports of the proceedings at the congress of the Royal Sanitary Institute and at the annual conference of the Sanitary Inspectors Association, attended by his officials, at which the need for a campaign to improve the standards of hygiene in the food trades was urged ; and whether he would make a statement.—Mr. J. STRACHEY replied : Yes, I have seen the reports. Under the Transfer of Functions (Food and Drugs) Order, 1948, which came into operation on March 1, and the several Public Health (Amendment) Regulations which came into operation on June 1, my department has taken over from the Ministry of Health the central responsibility for food inspection and food hygiene generally. It is my intention to seek the coöperation of local authorities and their officers, the food trade, and the public in a concerted effort to combat the dangers to health which result from the preparation, storage, or handling of food in unclean or otherwise unsatisfactory conditions. Unfortunately, shortage of essential equipment and of building labour and materials hamper immediate improvements in many directions. I believe, however, that existing legislation can be made more effective by voluntary and more detailed codes of practice applicable to particular trades, and by stimulating amongst all concerned a more positive attitude to food hygiene generally. In these matters my department will work in close consultation with the Ministry of Health, which remains responsible for measures for dealing with infected food and food-poisoning, and with the local authorities concerned with the enforcement of the relevant provisions of the Food and Drugs Act, 1938, and of the regulations made thereunder. I feel sure that I can rely upon all concerned—and not least the general public—to give their wholehearted support to this effort.

Scholarships for Medical Students

Mr. SOMERVILLE HASTINGS asked the Minister of Education what percentage of those now undergoing training as medical students in England and Wales were in receipt of maintenance scholarships from the Government and how these compared with pre-war figures.—Mr. GEORGE TOMLINSON replied : As stated by the Chancellor of the Exchequer on July 13 last, 2840 medical students out of a total of 9671 at universities in England and Wales are assisted with State awards. The number of medical students in 1937–38 was 8623 and the number holding State scholarships was 29.

Imports of Technical Publications

Replying to Mr. T. E. N. DRIBERG Mr. H. WILSON, presid of the Board of Trade, said that a further notice had bee sent to importers which amended the department's memora dum no. 281 of March 17 last. This new notice gave eff to the arrangements under which any person might for himself or on behalf of others single postal copies learned, scientific, technical, and religious periodicals print exclusively in a foreign language.

Treatment for Sexual Offenders

Mr. HECTOR HUGHES asked the Home Secretary if h attention had been drawn to the case of which details h been sent to him of a man of 82 described by the police as pest, against whom many complaints of interference wi young children had been made, who in East London w convicted of assault on a 4-year-old girl, and sent to pris for one month ; and what therapeutic treatment was provid in prison for this and similar cases.—Mr. CHUTER EDE replie I have obtained particulars about this conviction. Treatme is provided in prison in cases where it is likely to be of benef but it would be useless to attempt such treatment in th case in view of the age of the prisoner and the shortness his sentence.

Obituary

ISAIAH MORRIS

M.C., M.R.C.S., D.C.H.

Dr. Isaiah Morris was killed in Gallilee on June while commanding an Israeli medical unit. He w 30 years of age. Born in Glasgow, the youngest son Dr. Nathan Morris, he received his early education that city. He studied medicine at University Colleg Hospital, qualifying in 1942. During the invasion Europe he was awarded the Military Cross while servi as regimental medical officer to the 1st Suffolks. worked in England for over a year after his demobilis tion, and in November last he left for France, where worked for some months in camps for displaced perso For many years he had wished to practice as a childre doctor in Palestine, and he eventually reached th country this year.

" Isaiah Morris," writes a colleague, " was outstandi among his generation for the intensity with which thought and acted, and for the clear light of princi which guided him. He was naturally friendly ; gaiety and lightness of heart attracted people to him, they found a spirit of unbounded generosity and de humanity. He was a delightful colleague and co panion ; he had many friends, on whom his influe was profound. He set himself the highest standards life, and he lived up to them, selflessly devoting hims to the cause of the relief of suffering. He died as would have chosen to die, serving humanity among own people, where service was most needed."

Births, Marriages, and Deaths

BIRTHS

BRYCE-SMITH.—On July 26, at Oxford, the wife of Dr. Ro Bryce-Smith—a daughter.

GEAKE.—On July 24, at Woking, the wife of Dr. M. R. Ge —a son.

HALL-SMITH.—On July 21, at Hove, to Dr. Angela Hall-Smith Dr. Patrick Hall-Smith—a son.

OLLERENSHAW.—On July 28, at Cardiff, the wife of Dr. A. Ollerenshaw—a daughter.

SMITH.—On July 25, at Norwich, the wife of Dr. E. S. Or Smith—a son.

MARRIAGES

CORY—HORREX.—On July 28, at Woodbridge, R. F. P. Cory, c surgeon rear-admiral, R.N., retd., to Kathleen Horrex.

FITZPATRICK—TRAVERS.—On July 10, at Yelling, Hunts, J. Fitzpatrick, surgeon commander, R.N., to Eva Dionys

DEATHS

CASTELLAIN.—On July 23, Herménégild George Pourtalès Caste M.A. Oxfd, M.A., M.D. Camb.

DAVIES.—On July 29, at Colwyn Bay, Hugh Collin Davies, Glasg.

DICKSON.—On July 25, at Thames Ditton, Surrey, William A Dickson, M.D. St. And., M.R.C.P., F.R.C.S.E., D.P.H.

McIVER.—On July 24, Colin McIver, M.D. Edin., D.P.H., lt colonel, I.M.S. retd.

AFTERCARE OF THE AGED SICK

E. N. Thomson
M.B. Glasg.

M. Curran
M.B. Glasg., D.P.H.

> inquiries here, there and everywhere, but with meagre results . . ."
> *The Bishop of Truro, speaking of reports on old age in the* House of Lords, 1947.

At present patients are discharged from hospital and gotten until they become ill again. This may be isfactory with the ordinary adult, but in the elderly ime aftercare and general supervision are necessary. e have tried to find out just how necessary such help , and how it can best be applied; and to discover if e treatment in hospital has had results comparable ith those achieved in younger patients.

From the records of two Glasgow municipal hospitals e abstracted particulars of those men over 65 years of ge and women over 60 who had been discharged or ad died (technical discharge) during the winter months rom October, 1946, to March, 1947, inclusive. Between hese dates there were 757 discharges classified as follows:

A, Cardiovascular diseases
B, Pulmonary diseases
C, Alimentary tract diseases
D, Urinary tract diseases
E, Psychological disorders
F, Other conditions.

The hospitals concerned treat conditions of all types; hence every kind of illness is included in the survey. Where the disease was given in the record card as "senility" it was put into class F.

Of the 757 cases 201 were cardiovascular and only 91 pulmonary. One would have expected that, in a smoky city atmosphere, the pulmonary conditions would have been at least as common as the cardiovascular; but, with the rising tempo of industrial life, cardiovascular disease is assuming an increasingly serious position in the later years of life. Indeed, many cases diagnosed as bronchitis in the elderly are really slight pulmonary œdema resulting from a failing heart. Some physicians consider that a few râles in the lungs of those over 70 are to be expected as a normal concomitant of age. We cannot endorse this opinion. In healthy elderly persons we have found no such adventitious sounds.

Those discharged after treatment for cardiac conditions showed a great fear of doing anything that might put a "strain on their heart." They had nothing to think about all day except themselves, and they carried their worries to excess. Leading over-careful sedentary lives, they became more morbidly introspective than those who had been in hospital for other reasons. It is particularly in this type of case that something is required to take up their time and attention, and we thought that in twenty of these cardiovascular patients some therapeutic occupation could have been carried on with advantage. We prefer the term "therapeutic occupation" to the usual "occupational therapy," because the occupation is the dominant factor therapeutically, socially, and economically. Knitting, with the prospects of some financial reward to the old ladies, would be ideal for these heart cases if wool could be easily obtained.

One old lady had regular clients for dish-cloths made from string and sold for a few pence each. She was 78 years old and had been in hospital with auricular fibrillation.

Another lady, 84 years old, though almost blind made a happy time and a reasonable profit for herself by knitting men's socks from wool supplied by her customers.

One man cut ornamental spoons and letter-openers from odd pieces of wood; he gave away his products free, but we estimate that at today's values he could have made a profit of 1s. 6d. on each article.

These three people were among the most cheerful whom we visited, and they were pleased, like children, about the attention which their activities attracted; they showed no undue worry about their heart condition, and will probably outlive comparable people without a similar occupation. We believe that an elderly person who occupies himself with a hobby within his range of mental and physical power, especially one which he really enjoys, will not only live longer but also will have a lower sickness-rate than his opposite number who vegetates on his retirement; further, the satisfied cheerful elderly person contributes to the community an intangible something which reflects itself in the lives and work of those about them.

DEATHS IN HOSPITAL AND TRANSFERS

	Classification						
	A	*B*	*C*	*D*	*E*	*F*	*Total*
Died in hospital ..	106	23	23	19	6	40	217
Transferred to other hospitals	..	..	..	..	13	5	18
Transferred to public-assistance institutions	8	1	..	1	3	9	22
Total ..	114	24	23	20	22	54	257

In the six months under review 217 of the people in the chosen age-group had died, 18 had been transferred to other hospitals, and 22 had gone to public-assistance institutions. Cardiovascular disease accounted for about half of these deaths (106), and only 23 were in the pulmonary group. But in the latter four deaths from pulmonary tuberculosis are a reminder that tuberculosis as a lethal disease is not confined to the earlier half of life. These tuberculous patients were admitted with a diagnosis of bronchitis and, owing to lack of accommodation in the sanatoria and to impossible home conditions, had to be retained on humanitarian grounds in the general hospital. Duration in hospital varied from day of admission to 2476 days. Within 24 hours of admission 24 patients had died; we thought at first that some of these 24 had been kept waiting for a hospital bed for some time, and that the upset of their removal to hospital might have contributed to their early deaths there. However, this was not so; 22 had been admitted immediately on notification, and, of the remaining 2, one had been eleven days and the other six days on the waiting-list. They were mostly medical emergencies, such as coronary thrombosis and cerebral hæmorrhage. Table I gives the duration in hospital in weeks per age-group.

PATIENTS SENT HOME

We visited each of the remaining 500 patients, except 47 who could not be traced (lodgers or inmates of common lodging-houses), 17 who had gone too far away to be visited, and 118 who had died after leaving hospital (15 within a month of discharge, and 78 within three months, these deaths being spread more or less evenly over all the classifications). The stay in hospital of these 500 patients is given in table II.

The ordinary conception of disease in old age is one of long illness. Table II, however, shows that 161 of the 500 patients occupied a bed for only a month or less, and only 24 had done so for more than 199 days. These hospitals were not confined to the care of chronically ill or aged people, such as Affleck[1] investigated in Leeds, where 75% of the patients had been in hospital for more than a year. The proportion of 161 speedy discharges out of 500 shows that immediate active treatment of illness in the elderly in the acute wards of a hospital produces tangible results and may prevent the development of long-term illness. If these results are gained where there is no recognised geriatric unit, much more will be contributed to the prevention of chronic illness when an adequate, efficient, and interested section of the hospital staff is devoted to the treatment of elderly persons.

---

[1] Affleck, J. W. *Lancet*, 1947, i, 355.

Royal College of Surgeons of England

At a meeting of the council held on July 29, with Lord Webb-Johnson, the president, in the chair, Dr. Hubert Wyers was elected as the examiner for the diploma in industrial health.

The John Tomes prize for 1945–47 was awarded to Prof. H. H. Stones, in recognition of his research in dental pathology, and the Hallett prize to T. P. S. Powell, of the University of Edinburgh, on the result of the recent primary examination for the fellowship.

Diplomas of membership were granted to the following :

C. P. T. Alexander, M. J. Allwood, W. B. Ashby, R. H. R. Aston, Pamela M. Aviss, J. C. Barker, M. D. Begley, J. R. Bennett, S. Y. Bhagwat, J. M. Bishop, G. C. Blake, R. I. K. Blyth, W. O. Bradbury, M. A. Brennan, W. S. Brown, R. W. Buckley, P. I. Busfield, Anthea M. Bushby, P. J. A. Butcher, H. F. Cantwell, A. J. E. Cater, Ivor Chance, P. J. C. Chapman, Suzanne K. R. Clarke, Sybil M. Cockersell, Henry Collier, J. L. Cotton, D. N. Cow, D. T. Cox, Katherine S. M. Crouch, D. J. Crowther, Mary E. Curling, Katharina D. Dalton, F. J. Davies, H. F. Davies, N. C. R. Davies, F. A. de Hamel, Evelyn F. P. Dennett, J. A. L. Derlien, A. J. De Villiers, D. J. Douglass, G. E. Dower, E. C. Edwards, D. K. Evans, Shafik Fahmy, Paul Fehrsen, E. J. F. Filose, R. A. Fox-Linton, P. B. Foxwell, P. N. Gai, Phyllis A. George, J. A. H. Goldacre, Barbara M. Gray, A. M. Green, E. J. Hargadon, G. L. Harper, Michael Hatton, J. T. Hemingway, C. A. Higgins, J. F. Hindle, Henry Hollis, P. L. Holman, Jean M. Horton, John Humphreys, O. A. N. Husain, Rosemary Huxley-Williams, R. B. Jackson, F. E. James, A. G. Jarrans, Geraint Jones, J. H. Jones, Nesta J. Jones, C. H. G. Kendall, K. J. Kingsbury, Jan Koszyk, Norman Lawrence, Alexander Lebedeff, A. J. Lee, A. H. Levy, R. L. Lindon, H. A. Lomax, M. D. Lord, R. A. McGregor, J. W. R. McIntyre, S. A. Mannan, N. C. March, M. F. P. Marshall, A. P. Maruff, David Mendel, Marie D. Merchant, A. R. Merrill, J. A. R. Moody, W. P. C. R. Moody, Gwyn Morgan, K. Z. Novak, P. O. Oliver, G. R. Outwin, Sankar Panikkar, D. F. Parkin, C. A. Parsons, P. R. Persey, D. L. Postlethwaite, Elizabeth Preston-Thomas, Deonarine Ramdin, James Rankin, E. G. Rees, W. S. Richardson, Janet P. Rickard, D. G. B. Riddick, D. P. Rough, G. J. Schiller, D. L. Sladden, B. H. Smith, R. W. Smithells, R. S. Snell, Roy Southwell, W. F. W. Southwood, C. K. Spalding, J. R. Spears, R. A. Stanger, Rosemary Stephens, Alice H. Stokes, J. W. M. Stone, J. L. V. Summerhayes, E. F. Swift, Margaret N. A. Tew, R. G. Thomas, A. H. Thompson, J. B. Turtle, P. H. Venn, A. F. Verney, J. D. Villiers, D. L. Walker, Charles Waller, Daphne M. L. Walters, D. B. J. Wardle, W. K. M. C. Watkins, W. F. Weatherill, M. A. Weller, Audrey M. Wells, Margaret M. Whitaker, J. H. McN. White, Margaret P. Whittaker, Freda M. Wilcox, I. L. Wilkinson, J. L. Wilkinson, H. O. Williams, A. J. Woolf, Mary I. Wray

The following diplomas were granted jointly with the Royal College of Physicians :

D.P.H.—E. H. Annels, Fairfax Bell, Robert Calderwood, S. P. C. Casey, R. M. Coplans, E. J. Crowe, P. C. Dismorr, J. L. Fluker, A. W. Gilbert, J. L. Gordon, F. L. Groarke, Marjory I. H. Isaac, L. F. Jepson, A. F. H. Keatinge, J. W. McConachie, A. C. McLeish, Morris Price, Henry Richards, Peggy J. C. Roberts, Margaret I. Ross, G. G. Sheriff, M. I. Silverton, R. A. Smart, Ruth M. West.

D.A.—G. B. Badock, T. H. S. Burns, and J. R. S. Shields.

Faculty of Anæsthetists.—The following have been elected to the newly instituted fellowship of the faculty :

Helen B. Alcock, R. E. Apperly, Philip Ayre, Freda Bannister, R. A. Beaver, J. Blomfield, John Boyd, E. G. Bradbeer, R. J. B. Broad, G. Maxwell Brown, F. F. Cartwright, J. N. Cave, L. T. Clarke, R. J. Clausen, R. W. Cope, H. P. Crampton, A. S. Daly, C. J. Massey Dawkins, I. M. Campbell Dewar, H. W. Featherstone, D. Keir Fisher, R. Blair Gould, C. F. Hadfield, E. M. Handfield-Jones, R. P. Harbord, T. A. B. Harris, J. K. Hasler, B. P. Hill, E. Falkner Hill, M. W. P. Hudson, C. H. M. Hughes, John T. Hunter, Ronald Jarman, D. F. Johnson, W. J. Bennett Jones, Miss A. R. Kerridge, E. Landau, J. A. Lee, A. Goodman Levy, W. S. McConnell, V. O. McCormick, R. Machray, J. Ross Mackenzie, R. E. Mansfield, Z. Mennell, Edith Joan Millar, Arthur Mills, R. J. Minnitt, C. W. Morris, L. H. Morris, H. J. V. Morton, W. W. Mushin, M. D. Nosworthy, G. R. Phillips, H. H. Pinkerton, K. B. Pinson, A. F. Potter, W. B. Primrose, R. J. Probyn-Williams, B. Rait-Smith, H. A. Richards, E. H. Rink, Alison Ritchie, F. W. Roberts, S. Thompson Rowling, J. F. Ryan, E. A. Scott, W. M. Shearer, Sir Francis Shipway, O. L. C. Sibley, H. Sington, G. F. Rawdon Smith, R. L. Soper, C. E. Sykes, V. E. Vessell, F. F. Waddy, Sheina C. H. Watters, H. N. Webber, Humphrey B. Wilson, H. Bruce Wilson, H. Woodfield-Davies.

Faculty of Dental Surgery.—On July 16 the first annual meeting of the faculty was attended by some 100 fellows and licentiates in dental surgery, when Lord Webb-Johnson, P.R.C.S., gave a historical survey of the college and its association with dental surgery.

Prof. H. F. Humphreys has been re-elected and Prof. M. A. Rushton and Prof. H. H. Stone elected to the board of the faculty. Mr. R. R. Course has also been elected to the board as representative of the licentiates in dental surgery.

The following were admitted to the fellowship in dental surgery :

Prof. Andrew Francis Jackson, Prof. Sheldon Friel, Prof. J. C. Middleton Shaw, Miss K. C. Smyth, Mr. L. Russell Marsh, Mr. B. Maxwell Stephens.

Royal College of Surgeons of Edinburgh

At a meeting of the college held on July 28, with Mr. F Jardine, the president, in the chair, the following admitted to the fellowship :

S. J. Aptekar, H. W. C. Baillie, D. M. Bell, W. N. Boyd, W Brydone, D. E. Coyle, D. D. G. Curran, K. A. Dalal, V. J. D V. K. Drennan, John Evans, G. G. Farrington, Roger F G. E. Fordyce, J. M. Gold, D. F. P. Gordon, J. P. W. Grant, T Gray, F. S. Gregory, John Grieve, O. E. Hansen, G. V. H A. H. Haysom, Thomas Hunter, J. B. Jack, W. McK. S. K M. S. Khan, Douglas Laing, D. M. Lithgow, D. J. Living A. W. K. Main, Asa Mills, John Macpherson, A. W. MacQu P. M. Naidu, R. G. Patel, V. R. Rob, Fawzy Selim, A. McE. S Felicity E. Soutter, D. G. Steer, E. V. Strisiver, P. J. Tarpey, R Wilkins, J. W. Wilson.

Scottish Conjoint Board

Having passed the final examination, the following have b admitted licentiates of the Royal Colleges of Physicians Surgeons of Edinburgh and the Royal Faculty of Physici and Surgeons of Glasgow :

Freda M. Addly, A. K. Bain, R. G. Blair, J. A. Brown, D Bull, E. S. Cohen, Ruby M. Collister, Jessie McI. L. Duce, Hy Fishman, Abraham Freedman, L. I. Freeman, David Glam P. W. Grant, James Hamilton, Thomas Hannah, D. P. K. Ho N. D. Ker, Alexander Kilpatrick, Abram Kwasnik, G. H. I William Leggat, A. J. Levine, Audrey E. Lower, D. McN. McCurr A. W. D. MacIntyre, Jessie K. M. Main, H. M. Marks, Cather R. S. Mitchell, Margaret E. Morgan, Archie Muir, W. W. M Bernard Nash, Rosalie A. H. Paul, W. H. Reid, W. J. Reilly, B Seltzer, A. E. M. Sieger, *Eirlys Speek*, R. K. Steen, D. F. F. Stephe J. McC. H. Steven, John Stewart, Gwyneth Watkins, Margaret Watt, Sheila M. Wheeler, G. A. Whitefield, Lindsay Wilkie, Sop W. Wright.

Beit Memorial Fellowships

Mr. D. W. Logan, principal of the University of Lond has been elected a trustee of the fund. The following awa have been made :

SENIOR FELLOWSHIP

F. SANGER, B.SC. To study the structure of proteins with spec reference to insulin : at the department of biochemistry, Universi of Cambridge.

JUNIOR FELLOWSHIPS

D. A. DARCY, B.SC. To study the rôle of the lymphocyte a plasma cell in homograft breakdown : at the department of zool and comparative anatomy, University of Oxford.

R. M. C. DAWSON, B.SC. To study biochemical changes in brain associated with different forms of functional activity : the biochemical laboratories, Cardiff City Mental Hospital.

F. N. FASTIER, M.SC. To study the nature of the musculotr action of basic amidine derivatives : at the department of phar cology, University of Oxford.

L. J. HAYNES, PH.D. To study the synthesis of the coenzy cozymase : at the chemical laboratory, University of Cambri

A. T. JAMES, PH.D. To study the relationship between struc and biological activity in naturally occurring substances : at Lister Institute of Preventive Medicine, London.

A. MCCOUBREY, B.SC. To study analgesic and addic *tendencies from a chemical standpoint* : at the departments organic chemistry and pharmacology University of Leeds

S. W. STANBURY, M.B. To study the effect of changes in nerv activity, induced by narcosis and sleep, on the renal circulation blood-pressure in normal and hypertensive individuals ; at department of medicine, University of Manchester.

D. VERAL, M.B. To study the postural hypotension which r follow prolonged rest in bed : at the clinical research unit, Gu Hospital, London.

Minister Meets Chairmen of Executive Councils

Mr. Aneurin Bevan, Minister of Health, last week for the first time the chairmen of the 138 executive coun which have been set up under the National Health Serv Act. Mr. Bevan said that the vast majority of doctors w coöperating in the effort to make the new service a succ A number of authenticated cases had, however, been brou to his notice of doctors who were discriminating in select patients or in the standards of amenities provided for pu and private patients ; he believed that only a very sm minority of doctors were behaving in this way. He ho that any cases which came to light would at once investigated by the local medical committees.

Appointments

COOKE, R. T., M.D. Edin. : pathologist to the Hartlepools Hosp Management Committee.

Scunthorpe and District War Memorial Hospital :

BROWN, J. W., M.D., B.SC. Lond., F.R.C.P. : cardiologist.
MCALLISTER, V. P., M.B. N.U.I., F.R.C.S.E. : surgeon.
MILLAR, J. H. D., M.D. Belf., M.R.C.P. : physician.
MORTON, RALPH, M.B. Edin., F.R.C.S. : asst. ear, nose, and th surgeon.
ROLLASON, W. N., M.B. Birm., D.A. : anæsthetist.

Readmission to hospital has often caused heartache to urses and doctors. We have heard many complaints at patients recover, leave hospital, neglect treatment advice at home, are readmitted to hospital, are scharged well, return to the same environment and glect, and keep on being readmitted and discharged, ith progressively shorter spells at home, until finally ey die. Various remedies have been proposed for this, om the provision of special "chronic sick" hospitals the recommendation that "outside doctors" should ok after their patients better, and the provision of ecial nursing in the patients' homes. So far as our ries is concerned, readmissions were few: 4 patients ad been readmitted three times, and 3 patients twice; e rest had their only stay in hospital in the months nder review, except one stalwart admitted twelve times n the past four years for scabies and infestation with lice. erhaps the comparatively small number of patients who ass through hospital wards in the year makes the reappearance of a known face remarkable, and the readmissions are pt to gain an unwarranted importance because of the act that nurses and doctors know there is a long waiting-ist of sick and "here is this old lady back again."

Though not requiring readmission, 166 of the 269 old people would have benefited by extra attention. The magnificent work done by the nurses of the Glasgow District Nursing Association fails only in one respect—these girls have far too much to do, and it has been to our constant amazement to find them continually happy, bright, and kindly to their patients.

The Corporation of Glasgow has been taking an increasing interest in the nursing of the sick in their own homes, and this interest will be enhanced under he new Health Service Act. Home helps are also provided-for the elderly, irrespective of income, either for a whole day or part of a day. Since the inception of the outdoor medical service in Glasgow the services of a doctor have been available to any old-age pensioner in the city at any time of the day or night, free of charge, and each doctor has working with him a fully qualified and experienced nursing sister. *There is also in Glasgow a free ambulance service which will take a patient to hospital for special examination or treatment and return he patient to his home.

With all these services in view, we considered their pplication to the 166 people for whom we thought urther treatment was advisable. Visits by a doctor were required for 139, with the help of the nursing ister. These people had many minor ailments, and they equired the continuance of the supervision given in hospital. Since their discharge no medically qualified person had paid much attention to them, and a fair number had lost interest in their health; in fact, many of them had not seen a doctor since leaving hospital. With these old people the tactful and persuasive nurse is of inestimable value in inducing them to take more care of themselves and to see regularly to their medicines or dressings; hence for every visit by a doctor an average of four visits by the nurse is desirable to secure the application of the doctor's advice.

The ambulance service could have been used to convey to the outpatient department 17 patients in need of massage, radiant heat, or other particular treatment which could not be conveniently supplied at home. Domestic helps were desirable in 17 cases, but not for the whole day; the general tidying of the house and the preparation of a meal was all that was needed. The latter item will perhaps become less necessary with the recent introduction of a "meals on wheels" service under the Society of Social Service and staffed by the Women's Voluntary Services.

The two hospitals concerned admitted patients from all strata of society. Since the Local Government Act 1929 was implemented in Glasgow, they have taken an increasing share in the treatment of the general population and have not, as previously, been confined to those on the poor-law level. Home conditions varied greatly, but the large majority lay among the lower working classes, and it was pleasing to find that in 246 out of the 318 houses visited conditions were not inimical to the well-being of the patient either physically or mentally. We based our assessment of this on the general attitude of the friends and relations looking after the old people and on the domestic surroundings. As most general practitioners find, there is a perceptible atmosphere about a home where everything possible is being done for the patient's comfort. This faculty we used in deciding whether or not the general care of the patient was the best that circumstances permitted.

We next asked ourselves, "Has the condition of the patient regressed since discharge?" This was most difficult to answer, since we had not had an opportunity to examine them in hospital. However, by a careful perusal of the hospital record sheets, which were admirably detailed, we gained a fairly just assessment of the patient's condition on leaving hospital. Into this question also came the length of time between the date of discharge and the date of our visit, and we were glad to find that 242 of these elderly people had maintained the improvement which hospital treatment had brought about:

Has patient regressed since discharge?

Interval between discharge and visit	*Yes*	*No*	*Total*
1 month	3	10	13
2 months	2	10	12
3 ,,	2	11	13
4 ,,	7	17	24
5 ,,	6	17	23
6 ,,	2	6	8
7 ,,		11	11
8 ,,	1	7	8
9 ,, or over	53	153	206
Total	76	242	318

This recovery-rate is a great stimulus to those who care for the aged and a further step in the destruction of the attitude of hopelessness in the treatment of senile illnesses: "He is old; we can do little for him." The expressions of gratitude of these people for the benefit, comfort, and added life given to them by the efforts of the hospital staff were embarrassing, and we who have found our work among the elderly outside hospital gladly join them in this thankfulness. Another source of embarrassment, yet pleasure, for us was the delight voiced by and shown in the faces of the old people when they realised that we doctors had come to call on them to inquire into their state of health since their discharge from hospital. There is here a great field of worthwhile effort for interested doctors to maintain the good health of elderly patients who have had hospital treatment. In many cases we found that an expectorant mixture or a laxative or some such other slight medicinal treatment was required. The patient was not so ill as to send for a doctor, but we felt that, had the slight disability been allowed to continue, the health of the patient would eventually have deteriorated. Many of these elderly people are loth to send for a doctor, because they are afraid of being thought a nuisance.

RECOVERY HOMES

In 1946, among the elderly people outside hospital, only 51 out of 1001 were willing to go to a home for the aged, even though the conditions were described in rosy colours; yet 301 were willing to go to hospital. On this occasion only 10 out of 318 would have gone

PRESENT SOCIAL CONDITION

The care of the patients after their stay in hospital devolved mostly on relations and neighbours. Of the 318 examined in their own homes 10 were looked after by the spouse, 20 by other relations only, 5 by neighbours only, and 221 by a combination of relations and friends, but 62 relied on their own efforts for cooking and cleaning. Of the latter, 12 had been in hospital because of a cardiac condition, but we found them on the whole managing their affairs fairly well. In every case it was of their own volition that they were "on their own," since each had refused help from friends, and they insisted that they were happier and better in health when independent. The fact that only 5 relied on neighbours alone for domestic assistance is very satisfactory, and bears out what we have found in our everyday work—that, when the old person has been so ill as to require treatment in hospital, relations and friends gather round them on their discharge, and either the patient is taken to live in the home of a friend or someone comes to live as a companion with them. We found 24 of our patients confined completely to bed. It might seem strange that a hospital allowed them to be discharged in such a condition, but the explanation is fairly simple. Before discharge, the patients had all been able to get up, but too much sympathy on their home-coming led to their being more or less ordered by their unqualified nurses to "stay in bed for a day or two to recover your strength." The patients were quite fit to be up, and if left to their own devices would certainly have done so. However, after a day or two of super-mollycoddling they began to enjoy being spoiled, and thus gradually lost the power to rise at all. Time and time again we have found in our work that old people have been kept unnecessarily in bed, to their own great detriment; yet, if we suggest that the patient though perhaps paralysed on the right side, is capable of getting up 10–14 days after the onset of the lesion, we are looked on as "hard and not understand enough," and another doctor is sent for who is m sympathetic and agrees with those surrounding patient that "the heart is weak" and she should m no attempt to get up for four or five weeks. Howe at the end of this time, perhaps later, those respons for the care of the patient begin to get tired, and we called in again as hospital-admission officers to h the patient removed to hospital. Failing this course events, the patient really dies through being confined bed unnecessarily.

Apart from those confined to bed, 179 were capa of looking after themselves. This is an improvement the findings in the Glasgow investigation in 1946

	Present investigation (318 cases)		1946 investig (1001 case
Confined to bed ..	24 (7·5%)	..	286 (28 6%
Up but unable to care for self ..	115 (36·5%)	..	307 (30 7%
Able to care for self	179 (56%)	..	408 (40 7%

It seems evident that, had the patients requiring hosp treatment in the 1946 investigation been admitted improved to the same extent as in this survey, the perc age confined to bed would have been materially redu

Of the 318 people examined 49 should have l readmitted to hospital—17 for permanent stay 32 for active treatment. None of the alimentary urinary cases required to be retained in hospital. T was no necessity for the remaining 269 to be readmit for in this large proportion the cure had been so comp that they were able to take their places among the gen population once again. Whereas in 1946 it was fo that 31% of the old folk required admission to hosp in this investigation we found that, of those who had the advantage of indoor treatment, only required readmission.

ssue and it produces neither remote nor local body hanges." They found no evidence of reaction, either to foreign body or inflammation, when polythene was uried in body cavities or tissues. Guenther et al. (1947) ad already reported on the use of polythene tubing in enoclysis, and intravenous solutions had been kept unning into the same vein for two weeks.

Polythene has been used in the following surgical procedures by Brown et al. (1947): anastomoses of the common bile-duct, trachea, and pelvic colon; replacement or repair of the dura mater; peripheral nerve anastomoses; and cosmetic uses—e.g., to cover burr holes in the skull. Its use in palliative ventriculostomy in inoperable occlusion of the sylvian aqueduct has been suggested by Ingraham et al. (1947).

Exsanguination transfusions in hæmolytic disease of the newborn, with a single plastic catheter inserted into the umbilical vein, have been practised by Diamond (1947), and Arnold and Alford (1948) have described an additional technique with polythene tubing inserted into the long saphenous vein through an incision over the femoral triangle. Its use as a flexible cannula in venoclysis has been described in the U.S.A. by Guenther et al. (1947). In Great Britain, polythene tubing has been used for cardiac catheterisation, and by Mollison (1948) for obtaining specimens of blood "from the area of the portal vein" in the newborn.

Polythene is also in use for the insulation of radium and by virtue of its being chemically inert it is already appearing in some forms of chemical apparatus.

VENOCLYSIS IN INFANTS

Since the availability in this country of polythene tubing of British manufacture is not widely known to the medical profession, the present study was approached by a somewhat circuitous route. Specimens of plastic catheter suitable for venoclysis were obtained from America and submitted to Mr. N. D. Macleod, of Imperial Chemical Industries, Plastics Division. He confirmed what he had already suspected—that the catheters were made from polythene—and he immediately provided samples of 0·5 mm. bore for experimental purposes. Initial experiments having proved an unqualified success, the Telegraph Construction and Maintenance Co. Ltd. was approached with a view to supplying the tubing in bulk. This they did in bores of 0·5 mm., 1·0 mm., and 2·0 mm., at an average cost of 2s. for ten yards.

Sterilisation.—The tubing can be sterilised by boiling for 15 min. It is essential to ensure that the entire lumen is full of water before boiling, using a syringe for this purpose if necessary. Boiling interferes slightly with flexibility, but this action may be reduced to a minimum by "shock-cooling" the tubes direct from the steriliser to cold sterile water. Autoclaving at temperatures over 100°C cannot be used, and repeated boiling is inadvisable.

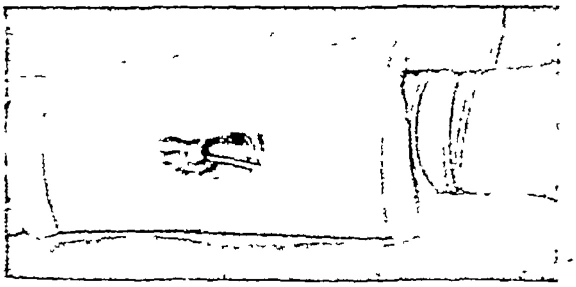
Sterilisation with antiseptics has been recommended by Diamond, who advocated 'Zephiran.' This antiseptic is of approximately neutral pH, has a non-selective and rapid bactericidal action in low dilutions, and is innocuous to man. It has no action on polythene. Surgical instruments can be sterilised in a minimum of 30 min. with a 1 in 1000 dilution of it. The antiseptic should be drawn up into the tube so that the entire lumen is filled before immersion in a vessel containing the sterilising agent. Before the tubing is used it should be immersed in a vessel of sterile saline and the lumen cleared by syringing. A few ounces of this product were released to us for the purposes of this investigation, but unfortunately it is not generally available in this country. Sections of tubing were exposed to a 1 in 1000 dilution of zephiran for an hour and for 24 hours before being cultured in broth.

Tests were also made on the efficiency of 'Dettol.' Sections of tubing were exposed to 2% and 5% dettol for 24 and 48 hours before being cultured in a broth medium.

Tubing was exposed to pure and 5% dettol for three weeks and was found to gain weight by 11% and 8% respectively, owing to the absorption of certain essential oils in the antiseptic causing a slight softening of the plastic but not true change in chemical composition. In view of this, however, it was decided to exclude dettol as a sterilising agent.

It is known that formalin vapour is used elsewhere for this purpose—the tubing being enclosed in a glass vessel with formalin tablets. Although this method is efficient traces of formalin are absorbed by polythene tubing and cannot be removed readily by washing but only by slow diffusion in air.

Cetrimide ('Cetavlon') shares, with zephiran, the advantage of being both highly bactericidal and relatively non-injurious to tissue. A 1% solution is of approximately neutral pH; it has no action upon, nor is it absorbed by, polythene.



Dressing with inspection window and turns of polythene tube round limb.

These various methods of sterilisation of polythene tubing proved uniformly efficacious. A non-sterile tube, gave a heavy growth of *Staph. aureus* after 24, 48, or 72 hours' incubation. But tubing submitted to boiling for 15 min., 2% dettol for 24 or 48 hours, 5% dettol for 24 or 48 hours, or 0·1% zephiran for 60 min. or 24 hours remained sterile in all cases after 72 hours' incubation.

Further non-sterile tubes gave a very heavy growth of *Staph. aureus*, *Bact. coli* and *Strep. fæcalis*; but after (*a*) immersion in 1% cetrimide for 24 hours, or (*b*) exposure to formalin vapour from dry tablets for 24 hours neither tube produced any growth during 72 hours' incubation.

Each method proved satisfactory from the bacteriological standpoint. Though zephiran is probably the agent of choice in the sterilisation of polythene tubing, sterilisation by immersion and storage in 1% cetrimide from which the tubes may be removed as required appears a satisfactory alternative. For this purpose we have used a glass tube of 1 or 2 in. diameter and 1 yard in length sealed at one end and stoppered with a rubber bung at the other. If this bung is penetrated by a smaller glass tube open to the interior of the larger but sealed externally and blown to form a chamber, the large tube may then be stoppered after filling with cetrimide and will contain no air bubbles—the latter being forced into the small chamber. This method has the advantage that the tubing may be sterilised without first being coiled and is more easily removed. Being lighter than water the polythene will float to the surface if attempts are made to sterilise it in a vessel of large surface area exposed to air. As an emergency measure, boiling for 15 min. followed by "shock-cooling" renders the tubes safe for use.

Assembly of Apparatus.—The standard apparatus for intravenous infusion is used as far as the adapter, where a needle of suitable bore for use with the polythene tube is fixed. The point of the needle is inserted into the to such a home, the remaining 308 giving a very definite refusal. The reason is not far to seek. When hospital admission is suggested, the patients know that they will probably be discharged in a few weeks after good nursing, a rest, and general care, apart from any medical or surgical treatment required. They know that when they leave hospital they will be returned to their own home, their own corner of the world, which has been kept open for them by relations or by the local authority. But they feel that there is a finality about going to a home for the aged. They will never return to their own fireside, and if they leave the home they will have no place to go to, because their houses will have been given to others.

Many of those admitted to hospital required only general medical or nursing care, impracticable in their home surroundings, but possible in a convalescent home; they did not need examination or treatment by a specialist, but could have been treated by a general practitioner, had their social condition been better. They would be pleased to go to such a recovery home, even for several months, because they know they would eventually come back to their own house. We suggest that, when planning for the old people's welfare, local authorities should consider the provision of such homes, with nursing care and with medical attention readily available. This would help to relieve some of the pressure on hospital beds in favour of those who require skilled treatment, and would diminish the number of elderly people entering the public-assistance institutions.

A modification of the system of screening advised by Affleck,[3] with the aim not of collecting similarly diseased conditions in the same ward but of selecting those who would do well in a recovery home, is well worthy of consideration. Admission to these homes could possibly be through the hospitals, where examination and accurate diagnosis by a specialist would reveal whether treatment in such a home would serve the patient as well as treatment in hospital. Some voluntary organisations already have such homes, and the Government are to be congratulated for the encouragement given to them by the National Assistance Bill.

The nursing in these recovery homes does not call for a full staff of trained nurses; a few such skilled people would be necessary, but most of the staff could quite well be assistant nurses or general helps. Such work could, with advantage to all, be included as part of a nurse's training. This would teach young nurses how to care for the elderly; it would be of advantage to the old people, and it has a third advantage. During their years of training young nurses would, for a period, live at the seaside or in the country—a great boon to a girl living in a hospital in industrial surroundings.

CONCLUSION

We have here given some of our impressions on elderly patients discharged from hospital, in the hope that this section of the population will not be forgotten in the future as they have been in the past. We would like in all humility to suggest to our medical colleagues, especially the more youthful, a very sobering thought in our treatment of old people. Though we can treat cases of appendicitis, pneumonia, tuberculosis, &c., quite impersonally, because we will possibly never suffer from these conditions, we will, all, barring early death, suffer old age. Therefore, even if from a selfish motive alone, let us give more care and thought to the present aged population, keeping in mind that any benefit we give them will be our inheritance.

Our sincere thanks are due to Dr. Stuart I. A. Laidlaw, medical officer of health for Glasgow, for his permission to publish and his help in preparing this paper; Miss Kay of Glasgow Public Health Department; and the clerical staffs of Stobhill and Southern General Hospitals.

SOME MEDICAL USES OF POL

WITH SPECIAL REFERENCE TO VENOCLYSIS IN INFANTS

JAMES W. FARQUHAR
M.B. Edin.

IAN C. LEWIS
M.B. Edin.

From the Royal Hospital for Sick Children, Edinburg

'POLYTHENE' is a plastic having physical and cher properties which make it suitable for a variety of purposes. Though it is a British invention, no of its medical application have been published in Englan with the exception of a reference to its use in the newbor by Mollison (1948); but it has been used extensive in America.

Chemical Properties.—Polythene is a solid compo of five hundred or more ethylene units linked togethe under conditions of high pressure and temperature, wit the aid of a catalyst. It is insoluble in all known solvent at room temperature; but benzene and other solvent act at temperatures above 60°C. It is complete resistant to the corrosive action of food chemicals, an it is not attacked by concentrated mineral acids, includin hydrofluoric acid, or by caustics. It has no action o nor is it attacked by, isotonic saline, Hartmann's solutio Darrow's solution, glucose solution, whole blood or plasm soluble sulphanilamide, sulphapyridine, sulphathiazol sulphacetamide, sulphadiazine, and sulphamezathin (N. D. Macleod, personal communication), penicilli (A. F. MacCabe, personal communication, Huelsebusc et al. 1946, Ingraham et al. 1947), or streptomyci (A. F. MacCabe, personal communication, Huelsebusc et al. 1946). No plasticiser or antioxidant is used in its manufacture.

Physical Properties.—The specific gravity of polythen is 0·92, and water absorption 0·01%. Polythene i transparent, and polythene film is transparent to X-ray The melting-point is 115°C. Polythene can be sterilis by boiling at 100°C, but repeated boiling of the tubin tends to cause cracks (see below). It cannot be sterilis in an autoclave. Shrinkage is less than 2% after boilin —i.e., dimensional stability is high. The substan remains flexible at −40°C. The elongation at break 400–500%. It can be extruded as tubing of any diame and produced as fine sheeting which does not t —e.g., when sutured—but can be cut to any shape wi scissors or a knife and is highly flexible and elasti It ignites and burns slowly. It is a poor conductor heat. It has a low coefficient of friction and a tensil strength of 1500–2000 lb. per sq. in.

History.—Polythene was invented in the laboratorie of Imperial Chemical Industries in England in 193 (Allen 1945). Production presented great difficulti but by 1938 these had been overcome and a pilot pla was running in that year, an experimental submarin cable being manufactured. A small quantity wa produced for television purposes in 1939, during whic year full-scale production began. From the outbreak o war in the autumn of 1939 polythene (under the tra name 'Alkathene') was largely used in the manufactu of radar apparatus throughout the war years. information about polythene was given to an Americ delegation in 1941, and the U.S.A. was in full producti by 1943.

MEDICAL APPLICATIONS

The inert character of polythene renders it suitabl for implantation into animal tissues. Reports o experimental implantation of tubing and film are already available in the U.S.A. Brown et al. (1947) reported "We do not believe it too early to state that polythen has great promise as a material for temporary or per manent surgical implantation in living tissue. . . . I does not undergo change when surrounded by livin sue and it produces neither remote nor local body changes." They found no evidence of reaction, either to foreign body or inflammation, when polythene was tried in body cavities or tissues. Guenther et al. (1947) had already reported on the use of polythene tubing in venoclysis, and intravenous solutions had been kept running into the same vein for two weeks.

Polythene has been used in the following surgical procedures by Brown et al. (1947): anastomoses of the common bile-duct, trachea, and pelvic colon: replacement or repair of the dura mater: peripheral nerve anastomoses: and cosmetic uses—e.g., to cover burr holes in the skull. Its use in palliative ventriculostomy in inoperable occlusion of the sylvian aqueduct has been reported by Ingraham et al. (1947).

Exsanguination transfusions in hæmolytic disease of the newborn, with a single plastic catheter inserted into the umbilical vein, have been practised by Diamond (1947), and Arnold and Alford (1948) have described an additional technique with polythene tubing inserted into the long saphenous vein through an incision over the femoral triangle. Its use as a flexible cannula in venoclysis has been described in the U.S.A. by Guenther et al. (1947). In Great Britain, polythene tubing has been used for cardiac catheterisation, and by Mollison (1948) for obtaining specimens of blood "from the area of the portal vein" in the newborn.

Polythene is also in use for the insulation of radium and by virtue of its being chemically inert it is already appearing in some forms of chemical apparatus.

VENOCLYSIS IN INFANTS

Since the availability in this country of polythene tubing of British manufacture is not widely known to the medical profession, the present study was approached by a somewhat circuitous route. Specimens of plastic catheter suitable for venoclysis were obtained from America and submitted to Mr. N. D. Macleod, of Imperial Chemical Industries, Plastics Division. He confirmed what he had already suspected—that the catheters were made from polythene—and he immediately provided samples of 0·5 mm. bore for experimental purposes. Initial experiments having proved an unqualified success, the Telegraph Construction and Maintenance Co. Ltd. was approached with a view to supplying the tubing in bulk. This they did in bores of 0·5 mm., 1·0 mm., and 2·0 mm., at an average cost of 2s. for ten yards.

Sterilisation.—The tubing can be sterilised by boiling for 15 min. It is essential to ensure that the entire lumen is full of water before boiling, using a syringe for this purpose if necessary. Boiling interferes slightly with flexibility, but this action may be reduced to a minimum by "shock-cooling" the tubes direct from the steriliser to cold sterile water. Autoclaving at temperatures over 100°C cannot be used, and repeated boiling is inadvisable.

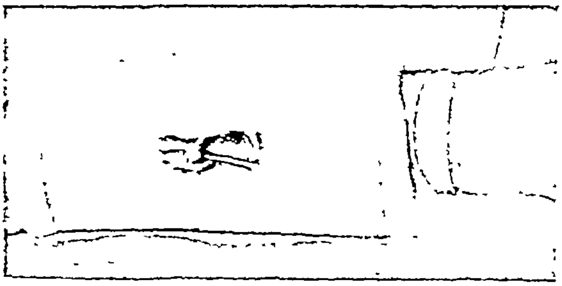
Sterilisation with antiseptics has been recommended by Diamond, who advocated 'Zephiran.' This antiseptic is of approximately neutral pH, has a non-selective and rapid bactericidal action in low dilutions, and is innocuous to man. It has no action on polythene. Surgical instruments can be sterilised in a minimum of 30 min. with a 1 in 1000 dilution of it. The antiseptic should be drawn up into the tube so that the entire lumen is filled before immersion in a vessel containing the sterilising agent. Before the tubing is used it should be immersed in a vessel of sterile saline and the lumen cleared by syringing. A few ounces of this product were released to us for the purposes of this investigation, but unfortunately it is not generally available in this country. Sections of tubing were exposed to a 1 in 1000 dilution of zephiran for an hour and for 24 hours before being cultured in broth.

Tests were also made on the efficiency of 'Dettol.' Sections of tubing were exposed to 2% and 5% dettol for 24 and 48 hours before being cultured in a broth medium.

Tubing was exposed to pure and 5% dettol for three weeks and was found to gain weight by 11% and 8% respectively, owing to the absorption of certain essential oils in the antiseptic causing a slight softening of the plastic but not true change in chemical composition. In view of this, however, it was decided to exclude dettol as a sterilising agent.

It is known that formalin vapour is used elsewhere for this purpose—the tubing being enclosed in a glass vessel with formalin tablets. Although this method is efficient traces of formalin are absorbed by polythene tubing and cannot be removed readily by washing but only by slow diffusion in air.

Cetrimide ('Cetavlon') shares, with zephiran, the advantage of being both highly bactericidal and relatively non-injurious to tissue. A 1% solution is of approximately neutral pH: it has no action upon, nor is it absorbed by, polythene.



Dressing with inspection window and turns of polythene tube round limb.

These various methods of sterilisation of polythene tubing proved uniformly efficacious. A non-sterile tube gave a heavy growth of *Staph. aureus* after 24, 48, or 72 hours' incubation. But tubing submitted to boiling for 15 min., 2% dettol for 24 or 48 hours, 5% dettol for 24 or 48 hours, or 0·1% zephiran for 60 min. or 24 hours remained sterile in all cases after 72 hours' incubation.

Further non-sterile tubes gave a very heavy growth of *Staph. aureus*, *Bact. coli* and *Strep. fæcalis*: but after (*a*) immersion in 1% cetrimide for 24 hours, or (*b*) exposure to formalin vapour from dry tablets for 24 hours neither tube produced any growth during 72 hours' incubation.

Each method proved satisfactory from the bacteriological standpoint. Though zephiran is probably the agent of choice in the sterilisation of polythene tubing, sterilisation by immersion and storage in 1% cetrimide from which the tubes may be removed as required appears a satisfactory alternative. For this purpose we have used a glass tube of 1 or 2 in. diameter and 1 yard in length sealed at one end and stoppered with a rubber bung at the other. If this bung is penetrated by a smaller glass tube open to the interior of the larger but sealed externally and blown to form a chamber, the large tube may then be stoppered after filling with cetrimide and will contain no air bubbles—the latter being forced into the small chamber. This method has the advantage that the tubing may be sterilised without first being coiled and is more easily removed. Being lighter than water the polythene will float to the surface if attempts are made to sterilise it in a vessel of large surface area exposed to air. As an emergency measure, boiling for 15 min. followed by "shock-cooling" renders the tubes safe for use.

Assembly of Apparatus.—The standard apparatus for intravenous infusion is used as far as the adapter, where a needle of suitable bore for use with the polythene tube is fixed. The point of the needle is inserted into the lumen of the tube, and the tube eased over the shaft of the needle to form a snug and watertight junction. Recently, we have tried to improve on this by using only 2 in. of rubber tubing below the viewing chamber, followed by 2 ft. of 2 mm. polythene tube which fits snugly over the adapter. This 2 mm. tube has a 1 mm. tube fitted into its lower end, and this in turn is fitted, if necessary, with 0·5 mm. tubing. Leakage at the junctions of these tubes, however, gradually assumes serious proportions. Unfortunately the extrusion process does not allow of variation in the bore of the tubing as it is manufactured: otherwise a tapered end would have been produced.

Polyisobutylene (P.I.B.) rendered plastic by a small amount of benzole makes a very satisfactory watertight union when smeared around the junction of two tubes. The union, however, is not a true bonding and will not resist tension although capable of standing up to considerable pressure within the lumen.

Insertion of Tube into Vein.—The ease with which polythene tubing is slipped into the smallest vein is striking. No stylet or introducer is required, the end of the tube being shaped with scissors to form a suitable bevel for the size of the vein. The tube is then slipped into the cut vein as usual and passed up for some inches before a retaining ligature is tied. The 0·5 mm. tube is suitable for fluids containing electrolytes only, and the 1 mm. bore should be used for blood or plasma. The latter can be readily slipped into a collapsed vein a third as wide as the tube. We have used a single suture to tie the tube to the skin about 1 in. from the incision. Using about 3 ft. of terminal tubing, three or four turns are taken round the limb before passing to the apparatus (see figure). This precautionary measure takes the strain of any unexpected violent tug and may also warm the fluid a little as it passes. Care should be taken not to allow the infusion to stop completely, because venous blood will otherwise pass back into the catheter and eventually clot.

The Dressing.—Earlier investigation made it more than probable that "drip sepsis" was due not to the operative procedure of cutting down but to removal of the dressing too often thereafter to examine the wound or to adjust a drip which was not running satisfactorily. To obviate this a window is cut in the sterile gauze dressing over the incision. Sealing this off is a single turn of sterilised polythene sheeting (see figure). This window enables the wound to be observed easily, and the dressing need not be removed until the drip is discontinued. The proximal end of the tube is at a considerable distance from the incision in case any adjustment should have to be made. The dressing is sufficiently open to prevent anaerobic culture of micro-organisms. Polythene film should never be applied directly over the wound and sealed.

RESULTS

We have now had experience of polythene tubes for some months and the results taken together with the American evidence, have stimulated us to publish this report in the belief that an advance has been made in the technique of venoclysis in infancy. Infusions have been kept running up to five days, and most of them were discontinued because they were no longer required.

Slight œdema is sometimes noted, but there has been no redness or appearance of inflammation. The œdema may have been secondary to a phlebitis due to persistent use of 5% glucose in babies.

The wounds compare favourably with those in which a metal needle or cannula has been inserted, and healing has been by first intention in all except a baby mongol with very poor peripheral circulation.

Blood and plasma flow readily through the 1 mm. No infusion has come to a standstill on its own.

We have recently made use of 1% cetrimide contai 1 in 500 acriflavine for preparation of the skin.

ADVANTAGES IN NURSING

The nurses in particular have found the polyth tubes a great boon, since the infant can be nursed a minimum of difficulty. The following are the cular advantages of using flexible polythene tubes venoclysis of infants:

(1) No limbs need to be splinted, since the highly flexi tube "gives with the vein" and will not rupture the ve wall or cause discomfort. This allows free movement, the baby's position can be changed at will. It also enab the operator to use veins, such as the short (external) saphena which previously were avoided if possible because of splinti difficulties. In splinting it is not unknown for the constricti bandages to cause venous obstruction. With polythe tubing this complication cannot arise.

(2) The great freedom of movement allows the nurse clean and change the baby easily when an infusion into saphenous vein is running. This is a great advantag particularly when it is necessary to treat sore buttocks.

(3) The limit of the baby's movement is the length of polythene tube, and so the baby is fed, as any other, besi the cot, the nurse having no cause for anxiety about th security of an infusion cannula or needle.

(4) Without any risk of damage or of impairing efficienc the baby can be wrapped up and taken to the theatre or th X-ray department, upstairs or downstairs, by one or, preferably, two persons.

(5) The baby is relieved of all the painful immobility o methods requiring splintage, with the associated dangers of hypostatic pneumonia, broken skin, and drip-wound infection

SUMMARY

Polythene is a flexible transparent plastic, easily sterilised, and innocuous to living tissue.

In the form of fine tubing, it is admirably suited for venoclysis in infants.

Polythene tubing is effectively sterilised by boiling or by soaking in cetrimide or zephiran.

Methods of preparing and introducing the tubes are discussed.

Risks of "drip sepsis" can be minimised by using a dressing with a polythene window which enables the "drip" wound to be inspected without disturbing the dressing.

We wish to thank Dr. Douglas Nicholson and Prof. R. W. B. Ellis for permission to use the tubing in the wards in their charge, and the latter for help and advice in the preparation of this article; Mr. N. D. Macleod, of Imperial Chemical Industries, Plastics Division, for his analysis of the American tubing, for assistance in investigating the chemical properties of special interest in its medical use, and for his help in obtaining supplies of polythene, 'Cetavlon,' and polyiso-butylene through the courtesy of I.C.I. and the Telegraph Construction and Maintenance Co. Ltd.; Dr. A. F. MacCabe, of the department of bacteriology, University of Edinburgh, for his investigation of the potency of streptomycin and penicillin after long exposure to polythene; the hospital laboratories for assistance in several of the experiments; and Messrs. Bayer Products Ltd. for supplying zephiran.

PULMONARY TUBERCULOSIS IN THE OLD

F. J. HEBBERT
M.D. Glasg.
From the University Medical Clinic, Stobhill Hospital, Glasgow

MANY doctors think that pulmonary tuberculosis in the aged is chronic and relatively benign and do not realise that it is not uncommon and may be highly infective.

Amberson (1943) attributes most cases to reactivation of old lesions. Arnstein (1941) has produced evidence of pneumoconiotic lesions in aged city-dwellers, unconnected with industrial hazards, which may light up healed foci. Dublin (1941) shows that the peak incidence of tuberculosis in adult males is at the age of sixty-five. Harpøth (1941) notes that in 85 out of 950 new cases in Copenhagen in 1939 the patients were over fifty-five. Harrell (1944) has drawn attention to the misleading nature of mortality figures, since many of these patients do not die "tuberculosis deaths." Post-mortem surveys (Taubert 1925, Schlesinger 1929, Freeman and Heiken 1941), have demonstrated not only the frequency but also the widespread character of tuberculosis in the old, scarcely any organ being exempt, and the miliary form being not infrequent.

The symptoms are insidious and may be masked by the general process of ageing. The infectivity of the older subject is generally accepted. Trossarelli and Lanino (1938) found sputum-positive cases, previously unsuspected, among the inmates of an old people's home, and Miller and Henderson (1942) observed symptomless cases with persistently positive sputa over a period of years in their series. The proportion of sputum-positive cases varies in different reports and is influenced by the thoroughness of methods used. Figures from 41% (Joress 1938) to 79·1% (Banyai 1930) and even higher have been found.

There is on the whole a predominance of men in series reported. Patoir (1938) thought the proportion of men to women was 2 : 1 ; this figure is also given by Amberson (1943). The influence of various factors contributing to this is discussed by Rich (1944).

THE PRESENT SERIES

My cases are collected from the records of a unit in general wards with a fairly high admission-rate of older patients. In 1938–46 the number of patients aged over sixty found to have tuberculosis was 69. As in all retrospective research, one difficulty was the factor of personal observation of the individual responsible for the case-records, and this necessitated care in the interpretation of data and the rejection of some cases in which the necessary criteria had not been fulfilled. Diagnosis was radiological and clinical, with confirmation where possible by sputum examination, and in a few cases by necropsy.

There were 60 men and 9 women. One cause of the larger number of men appears to be that many old men live in "model lodging houses" and similar places, and of necessity go to hospital with ailments which call for nursing. The age-distribution was as follows, the youngest being sixty and the oldest eighty-two.

Age	*Men*	*Women*
60–65	18	2
65–70	23	1
70–75	12	3
75–80	5	2
80 plus	2	1

Most of the men had been heavy manual workers. The series included 4 stone-masons, 2 miners, and 1 knife-grinder, none of whom showed any radiological sign of pneumoconiosis, and 1 miner diagnosed radiologically as a case of anthracosis.

The diagnoses made before the patients were admitted to hospital varied considerably: 4 cases had already been diagnosed as pulmonary tuberculosis and had been treated in dispensaries; 27 patients were admitted with bronchitis, 7 with cancer of different organs, 6 because of senility, and the remainder with miscellaneous complaints.

SPUTUM

In 34 cases, or almost half, tubercle bacilli were found in the sputum by examination of routine smears; in some cases the examination was carried out after antiformin concentration. On investigation it was found that in 30 of the cases which gave negative results, insufficient examinations had been carried out to exclude the presence of tubercle bacilli with certainty—e.g., when patients with advanced tuberculosis died soon after admission.

FINDINGS POST MORTEM

Only 5 cases came to necropsy:

Case 1.—A man, aged 78, had extensive active tuberculosis with caseation and cavitation of both lungs. The pleural cavities were nearly obliterated by adhesions: and there was also tuberculous epididymitis.

Case 2.—A woman, aged 61, had been diagnosed radiologically as having apical tuberculosis, probably a reactivated old lesion, in 1938. In 1940 necropsy revealed chronic bilateral pulmonary tuberculosis, with fibrosis and cavities as large as peas, numerous new tubercles in both lungs, and tuberculous bronchopneumonia.

Case 3.—A man, aged 70, had miliary tuberculosis, with tuberculous bronchiectatic cavities in both lungs and tuberculous meningitis. He had been examined a year before, and right apical tuberculosis had been diagnosed; no tubercle bacilli were found in the sputum in nine examinations in five weeks.

Case 4.—A man, aged 64, had cancer of the large bowel and pulmonary tuberculosis. At necropsy active tuberculous bronchopneumonia, with numerous new nodules in both lungs, was found.

Case 5.—A man, aged 70, with negative sputum, had been diagnosed radiologically as having fibroid phthisis, with minimal physical signs. At necropsy indications of activity were found, but the process was limited.

This very small series of necropsies covers a large field of pathology of tuberculosis in the old, and shows that the disease progressed rapidly.

FAMILY HISTORY

Full studies of family history in this type of patient, with reference to tuberculosis, are uncommon, but a careful study was made by Snell (1941) covering preceding and succeeding generations. In the present series, out of 60 patients from whom a reasonably full history was obtained, a strongly suggestive or positive family history was elicited in 13 cases (22%). It must be remembered that in most cases in which a patient's parents have attained the age of seventy or thereabouts, they are described as having died of "old age" unless something dramatic happened—e.g., a cerebral vascular lesion.

A previous history of pleurisy or of treatment for tuberculosis was given in 20 cases out of 63 (32%).

ONSET

Symptoms of onset were in most cases vague. It is impossible to assess these accurately, since many of these patients are poor witnesses, but the main symptoms of onset in 63 cases were:

Symptom	*No. of cases*
Cough	31 (*49%*)
Weakness	10 (*16%*)
Chest pain	8 (*13%*)
Dyspnœa	7 (*11%*)
Hæmoptysis	3 (*5%*)
Loss of weight	3 (*5%*)
Hoarseness	1 (*2%*)

The initial symptoms lasted from a few hours, in the case of chest pain, to twenty years in the case of cough, but no purpose would be served by trying to assess this, for some patients had merely given "a long time" as the period.

SYMPTOMS OF ESTABLISHED CASES

Cough was complained of in 64 cases (94%), usually with sputum. Figures in other series are 96% (Brooks and Lander 1938), 96% (Almansa de Cara 1945), 95% (Freeman and Heiken 1941), and 79% (Harpøth 1941).

Loss of weight was admitted by 55 patients (80%). This contrasts with 82% (Freeman and Heiken 1941), 42% (Brooks and Lander 1938), and 43% (Joress 1938). This figure reflects to some extent the poor state of nutrition and defective dietary of many older patients admitted to hospital. Harrell (1944) has stated that pronounced loss of weight is an important feature of this disease in the old as compared with younger patients, and Almansa de Cara (1945) considers that the state of nutrition is usually well maintained but may deteriorate with extreme rapidity, once the lesions become active.

Dyspnœa was complained of by 55 patients (80%) and was severe in many. It must be remembered that Glasgow is a city of tenements, which may explain this figure compared with 15% (Harpøth 1941), 42% (Joress 1938), 55% (Brooks and Lander 1938), and 68% (Freeman and Heiken 1941).

Hæmoptysis, from staining of the sputum to a loss of some ounces of blood, occurred in 20 cases (29%). Figures in other series are 17% (Joress 1938), 35% (Brooks and Lander 1938), 36% (Harpøth 1941), 46% (Freeman and Heiken 1941), 37% (Harrell 1944), and 45% (Almansa de Cara 1945).

Night-sweats occurred to a well-marked degree in 12 patients (17%). Other figures are 17% (Joress 1938), 35% (Freeman and Heiken 1941), 11% (Almansa de Cara 1945), and 8% (Brooks and Lander 1938).

Pyrexia.—In 35 cases (51%) there were definite rises in temperature varying from a continuous irregular pyrexia (usually a terminal phenomenon) to an occasional peak of a few hours' duration. Of these 35 patients 27 died in hospital. Other studies give the following incidence of pyrexia: 51% (Freeman and Heiken 1941), 14% (Harpøth 1941), 20% (Brooks and Lander 1938) and 23% (Almansa de Cara 1945).

CLINICAL FINDINGS

Radiological reports were available in 57 cases (83%). Fibroid disease was present in 29 cases (51% of those examined), and it was bilateral in 15 (26%). Active (fibrocaseous) disease, sometimes accompanied by fibroid disease elsewhere, was found in 24 cases (42%). This was bilateral in 8 (14%). Unclassified cases numbered 4. Pleural effusion was observed in 5 patients, tuberculous bronchopneumonia in 2, extensive fibrosis with mediastinal shift in 4, diaphragmatic adhesions in 1, and bronchiectasis in 1. Anthracosis with a fibroid lesion was noted in 1. Well-marked cavitation was seen in 13 patients (23%). Other series show a similar general picture, though the incidence of cavitation reported is usually higher—e.g., 28 cases out of 60 (Joress 1938).

Pulmonary Complications.—Pleural friction was detected in 9 patients (13%), and effusion developed in 5 (7%). Asthma was present in 1 case. Other series also show a low incidence of asthma—e.g., 3% (Rest 1942).

Concomitant Diseases.—Diabetes was present in 3 cases (4%). Figures in other series are 7% (Brooks and Lander 1938), 13% (Joress 1938), 11% (Freeman and Heiken 1941), and nearly 2% (Snell 1941).

Evidence of cardiovascular disease was detailed in 11 patients as follows:

Cardiac failure of different types ..	5
Auricular fibrillation	2
Paroxysmal tachycardia	1
Aortic regurgitation (syphilitic).. ..	1
Essential hypertension	2

Lesions of the central nervous system were noted 5 patients, and carcinoma of the stomach, gastric and carcinoma of the colon each occurred in 1.

Among general findings it was noted that cyanosis uncommon in the absence of heart-failure, and 29% of cases showed some degree of clubbing (Brooks and Lander's figure is 30%).

Erythrocyte-sedimentation Rate (Westergren).—The was determined in 42 cases as follows:

		No. of cases
Normal or slight increase	(under 15 mm. in 1 hr.)..	2 (5%)
Moderate increase	(over 15 mm. ,, ,,)..	9 (21%)
Considerable increase	(over 40 mm. ,, ,,)..	23 (55%)
Extreme increase	(over 80 mm. ,, ,,)..	8 (19%)

In moderate degrees of anæmia this method is reasonably accurate. There is a tendency for the E.S.R. to rise in old age in the apparently healthy. Almansa de Cara (1945) found readings of 5–80 mm. (Westergren), 75% of cases being over 25 mm.

Hæmatological Findings.—A degree of anæmia was usual but not universal. Hæmoglobin levels ranged from 5·5 g. to 15·5 g. per 100 ml., the average level being 11·9 g. (A reduced Hb level may be found in the aged with, so far as can be ascertained, no organic disease. Levels of 12·65 g. in men and 11·7 g. in women have been reported by Newman and Gitlow (1943) and 12·9 g. by Fowler *et al.* (1941). Their figures appear to correspond with the normal found in the aged in hospital practice in Glasgow in our experience.) Where complete blood examination was carried out, the anæmia was normochromic, except in some patients with greatly reduced Hb levels, when a hypochromic microcytic anæmia was found.

SUBSEQUENT HISTORY

The outcome in this series was as follows:

	No. of patients	*Sputum positive*	*Sputum negative*
Died	41 ..	21 ..	20
In status quo.. ..	6 ..	3 ..	3
Improved	20 .	8 ..	12
Still in hospital ..	2 ..	2	

DISCUSSION

No treatment beyond rest and symptomatic measures was given. Though in some reported series a more active treatment was attempted, the consensus of opinion appears to be that in the main these are not cases suited to drastic measures. Collapse therapy, for instance, is seldom desirable. Almansa de Cara (1945) cites successful cases of artificial pneumothorax at the ages of 52, 57, and 62, but admits that it is not usually well tolerated. Amberson (1943) considers that there may sometimes be a place for surgical measures.

There appears to be no prospect of getting these patients into sanatoria at present, though many of Brooks and Lander's (1938) patients did in fact go on to sanatoria. It is of no use today to be content to say that the future of the country lies with the young, and to leave the older tuberculous patients to their own devices. Apart from other considerations, which are many and important, the welfare of infants, children, and adolescents may be greatly imperilled. While the aged patients are in general wards, some attempt must be made to isolate them, but even this is sometimes difficult, as will be appreciated by anyone with experience of ward work with a large number of the older sick.

Pulmonary tuberculosis in the old is usually of insidious onset and may be completely masked by other disabilities, or often ignored until either an intercurrent illness or a sudden increase in activity of the tuberculosis leads to an illness which may, even at this stage, be treated as nothing out of the ordinary in an aged person. In such cases pulmonary changes may be gross before tuberculosis is diagnosed. The applicability of certain necropsy findings to this country may be disputed—e.g., reeman and Heiken's (1941) series contained a large inority of negroes—but it is clear that large-scale vestigation of the older sick would reveal a surprisingly rge number of tuberculous patients, about half of whom robably would have active lesions, and well over alf would have positive sputum. Isolation of these atients is impossible. Many can undoubtedly remain their homes with certain safeguards, but the establish- ent of separate communities might have to be onsidered.

Fibroid cases may become active, and routine periodical adiological examination of established cases, especially here sputum-positive, should be possible.

SUMMARY

More attention should be directed to the problem of ulmonary tuberculosis in the old, which is often an ctive process with a high proportion of sputum-positive ases.

The onset is insidious, and the symptoms are commonly scribed to old age.

Cases appear to be commoner among men than among women.

Of a series of 60 men and 9 women, diagnosed in general wards, half had positive sputum—a low estimate. In 5 necropsies a wide variety of tuberculous disease was seen.

Cough, loss of weight, and hæmoptysis were the principal symptoms. Radiological findings corresponded to those reported for larger series by other workers, fibroid phthisis being present in half the cases. A raised erythrocyte-sedimentation rate and anæmia were usual.

Acknowledgements are due to the late Prof. Noah Morris for his interest and advice; Dr. A. Slessor for criticisms; Dr. A. D. Briggs for his interest and facilities to examine past case-records and to Dr. F. E. Reynolds for bacteriology and access to post-mortem records.

"... In all this matter of the English national tradition we are still living on capital, for tradition is not dissipated in one generation or two. But we have quite obviously in the last forty years erected a general structure designed for a proletariat of irresponsible individuals, seeing how easily they can, as individuals, get by, whereas the older tradition impressed on people from a very early age that they must expect to depend upon their own exertions. This self-reliance was the essential complement of a spirit of independence towards the Government, for the worst possible combination is that of which the old Roman writers complained so much, of the Roman crowd at once expecting to be carried, dependent, and yet intractable. Bismarck, who knew his people, made them dependent and more tractable than ever. But the English tradition was until this century just the opposite, of men who stood firmly, and rejoiced to stand, on their own feet; and yet, almost unobserved, it has been abandoned and reversed."—Mr. DOUGLAS WOODRUFF, in *Soundings*, July, 1948.

REFRIGERATED AUTOGENOUS SKIN GRAFTING

A REVIEW OF 50 CASES

ADRIAN E. FLATT
M.B. Camb.

From the Plastic Surgery Unit, Ministry of Pensions Hospital, Stoke Mandeville

THREE papers recording the results of clinical trials of refrigerated skin-grafts have been published in recent years. Webster, of New York, began refrigerating skin-grafts in 1932 but did not publish his results until 1944. He records the results of 36 trials of refrigerated grafts, some being autografts, some homografts, some full-thickness, and some split skin-grafts. In general, he showed that it was practicable to keep skin alive by refrigeration and that split skin-grafts showed a better take than full-thickness skin-grafts. Strumia and Hodge (1945) experimentally grafted skin which had been stored at temperatures ranging from −20 to −25°C for periods up to 61 days with satisfactory results. Matthews (1945) used refrigerated grafts of various thicknesses, though none were of the full-thickness type. He used the method of Young and Favata (1944) of contact coagulation for the fixation of his grafts, and states that "when the first dressings were taken down, the grafts were found to have taken satisfactorily"; he publishes some impressive photographs to support his statement.

Since Matthews (1945), de Martigny (1913), and Carrel (1912) have commented on the apparent increased vitality of refrigerated grafts as compared with normal skin, it was decided to try to graft infected areas with refrigerated skin. This paper reports the results of the first 50 applications of refrigerated grafts stored by a simpler method than has previously been described, and applied to both "clean" and infected granulating areas.

Both Webster and Matthews used an ordinary refrigerator to store the skin at a temperature of 3–6°C. It was felt that, if possible, the temperature for storage should be constant, and hourly readings for 24 hours were taken in various parts of two ward refrigerators which were in constant use. It was found that there

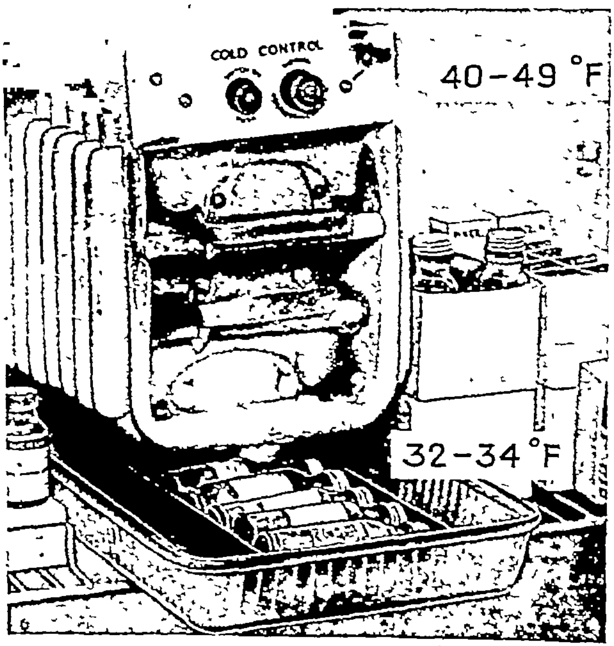

Fig. 1—Position of storage of skin-grafts in refrigerator.

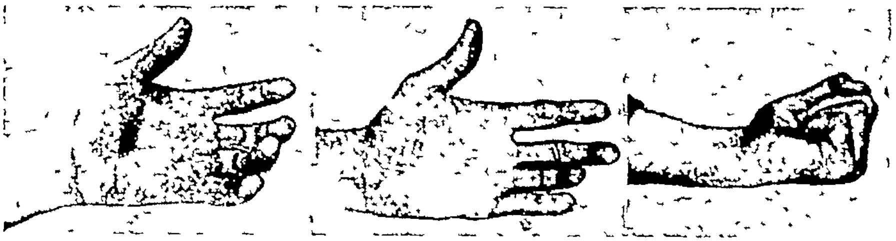

Fig. 2—Clean electric burns treated with refrigerated skin-grafts (case 1).

was a variation of 9°F (40–49°F) over 24 hours in the area adjacent to the cooling coil. However, the area inside the dish placed to collect drops from the condensed moisture on the coil did not show a variation greater than 2°F (32–34°F). This area was therefore selected for the storage bottles (fig. 1).

Webster stored his grafts by wrapping the skin in 'Pliofilm' sheets and then in two sterile towels, the package being labelled and left in the refrigerator.

This method of storage was rejected as being too bulky, and a modification of the method described by Matthews was adopted. He recommended that the graft should be folded with its raw surfaces opposed, wrapped in a piece of tulle gras, and this in turn in a piece of gauze tightly wrung out of normal saline. It was to be held away from the small amount of fluid which collected in the bottle by inserting a ring of rubber tubing or lead foil for it to rest on.

In my method the graft is spread on tulle gras and folded in half with its raw surfaces opposed. The graft sandwiched between tulle gras is now placed on a fresh square of tulle gras and rolled tightly up into a cylinder, each end being twisted once or twice, toffee-paper fashion. The cylinder is placed in an ordinary 20 ml. screw-topped glass pathological specimen-bottle. Saline gauze can be safely discarded from the technique of skin preservation, any additional moisture being unnecessary and possibly even harmful.

The risk of drying of the graft can be eliminated if the tightly rolled cylinder is pulled between the finger and thumb a few times, thereby spreading the excess of soft paraffin over the surface to form an enveloping greasy coat.

CLINICAL APPLICATIONS

The 50 applications of skin were performed on 17 patients with various lesions. No attempt was made to select cases other than to choose, if possible, chronically infected granulating areas. The lesions grafted consisted of:

	No. of cases	No of applications
Burns:		
Thermal	7	18
Electric	2	10
X-ray	1	2
Failed Thiersch grafts	4	14
Traumatic full-thickness skin loss	2	5
Varicose ulcer	1	1

The patients were aged
years, and most of them
male.

All the grafts were of the
skin type cut whenever po
with the same knife adjusted
the same thickness. Before
cation the grafts were al
cut into squares of side 1
(or multiples of 1 cm.) so t
by using a graft of co
size, percentage takes could
more accurately assessed. All grafting was done in th ward as a bedside dressing.

When required for use the bottle was taken from store, the tulle gras unrolled with full sterile precaution the requisite amount of skin cut off, and the remainde immediately rolled up and put back in the refrigerato before the application of skin. A bacteriological swa was always taken from the recipient area before grafting and a penicillin-sulphathiazole powder was usuall applied to the area before the placing of the graft The grafts were placed directly on the granulating are with no additional means of fixation, and a saline gau cotton-wool pressure dressing was invariably applied

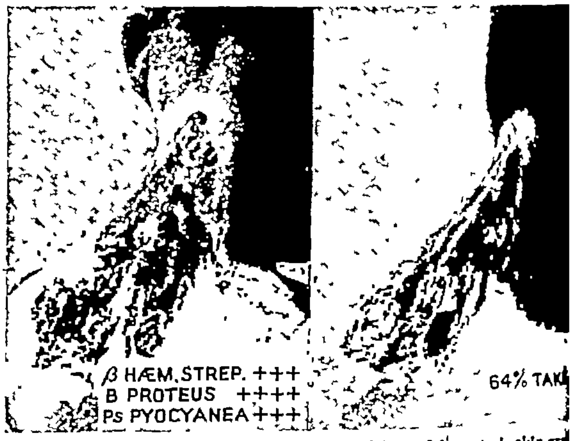

Fig. 3—Infected X-ray burn treated with refrigerated skin-gr (case 2).

Grafts were always left undisturbed for 48 hours and we usually left 4 days before the first dressing was done

No matter how dirty was the recipient area, t exudate was wiped away, and any sloughs present we cut down to a bleeding base wherever possible. Ma of the cases yielded only *Staph. pyogenes* and diphthero on culture, and would therefore not be regarded infected in the sense that the take of fresh grafts mig be affected; β-hæmolytic streptococci, *Proteus vulgar* and *Ps. pyocyanea* were all regarded as infecting organis and one or more of these organisms were present 20 of the 50 cases reported.

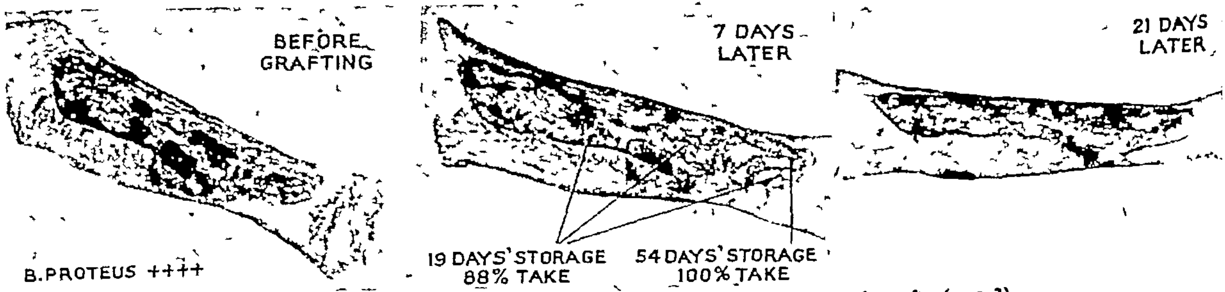

Fig. 4—Filariasis, infected by B. proteus, treated with refrigerated skin-grafts (case 3).

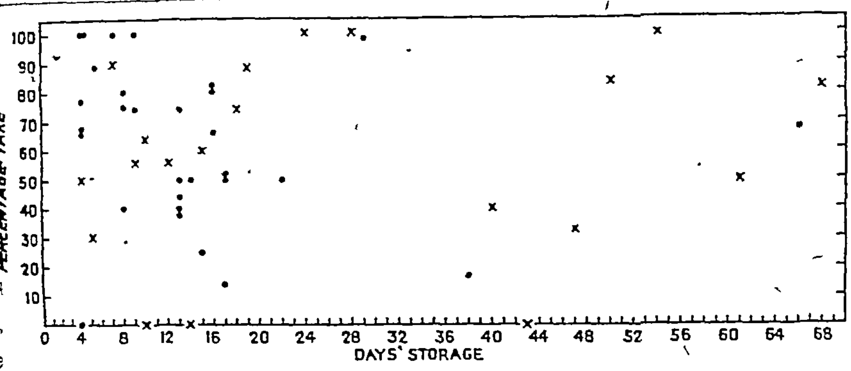

Fig. 5—Scatter graph showing percentage take of refrigerated skin-grafts plotted against storage time: •, grafts on "clean" areas; x, grafts on infected areas.

ILLUSTRATIVE CASE-RECORDS

Case 1 (clean case).—Electric burns from grasping a 2,000 V electric grid cable. Deep burns with tenacious sloughs involving the tendon sheaths of the 2nd and 3rd digits and exposing the tendons of the 4th and 5th digits. Treated with 5% 'Milton' irrigations in a Bunyan-Stannard envelope. Later, primary grafting to granulations at periphery of burns and excision of sloughs. Refrigerated skin applied to remaining areas as granulations appeared. After four months' manual labour there is some contraction, but the refrigerated skin is durable (fig. 2).

Case 2 (infected case).—Necrosis of three years' duration following X-ray therapy for spondylitis ankylopoietica. In fig. 3 the illustration on the left shows the result produced by fresh grafting the whole ulcer area. That on the right shows the result obtained by a single application of skin taken and stored at the time of the first grafting operation.

Case 3 (infected case).—Elephantiasis (*Filaria bancrofti*) treated by excision of skin and subcutaneous tissue and by massive sheet grafting. Moth-eaten appearance due to *B. proteus* infection. The illustrations (fig. 4) show the result obtained by refrigerated grafting.

RESULTS

In all "infected" cases it was considered economical to try grafting, and in only 3 did the skin totally fail to take. Three cases yielded 30%, 33%, and 40% take, but the remainder showed a 50% take or more, 3 cases showing 100%. The "clean" cases showed percentage takes varying from 0 to 100%; three-quarters showing a 50% take or more. All total failures were explained by inadequate immobilisation of the freshly applied grafts, except in one "clean" recipient area for which no obvious explanation could be found.

The scatter graph (fig. 5) shows the percentage take plotted against storage time. The percentage take was calculated from the number of grafts applied; where only a few grafts had been applied a percentage figure is open to question, but no more accurate graphic presentation could be found.

As would be expected, the shorter times of storage yielded a higher percentage take, but even the longer times of storage yielded a satisfactory take. The skin was usually used for grafting within the first three weeks of storage, but the occasional use of skin stored after this period proved satisfactory, the longest storage time—68 days—yielding 82% take. Skin has been stored for much longer periods; even after 6 months the cut surface has been moist and the blood present has remained liquid. Histologically this skin looked normal, did not differ from other sections of stored skin, and would probably have been satisfactory if occasion had arisen for its use.

The thinner the graft the more rapidly it became vascularised from beneath. The thicker split skin-grafts usually separated into two layers, a lower adherent layer and an upper layer which separated with the tulle gras on which the graft was spread. The lower and thicker layer was usually a dead white but firmly adherent after a week's implantation. During the second week this white slough-like area showed scattered areas of vascularity, and between the 14th and 18th days became rapidly epithelised, showing by the 21st day a normal skin surface. Biopsy of this showed that the adherent mass was dermis, and epithelisation had therefore taken place by lateral spread from the deeper epithelial elements.

CONCLUSION

Though the present series is small, it is felt that this simple method of skin storage and application is justified.

The results tend to substantiate the views of other writers that refrigerated grafts possess an increased vitality, and the "infected" cases in this series show that it is economical to apply stored skin-grafts to areas to which fresh grafting is not usually carried out because of bacterial flora.

The patients have in many instances been saved repeated operations and had their hospital stay shortened by having skin available at the different times at which the recipient area became suitable for grafting.

The work was done at the Ministry of Pensions Hospital, Stoke Mandeville, and my thanks are due to the Director-General of the Ministry of Pensions Medical Services for permission to publish this paper, to Mr. Richard Battle for his help throughout the investigation, and to Mr. R. G. Mason for his help in photographing the cases.

A STUDENT HEALTH SERVICE

R. E. Verney
M.B. Edin., F.R.C.P.E., D.R.
SENIOR PHYSICIAN TO THE UNIVERSITY OF EDINBURGH STUDENT HEALTH SERVICE

R. F. Robertson
M.B. Edin., M.R.C.P.E.
ASSISTANT PHYSICIAN TO THE UNIVERSITY OF EDINBURGH STUDENT HEALTH SERVICE

The growth of interest in the health of the university student is reflected in the recent conference at the Institute of Social Medicine in Oxford and in the publication of the papers presented there. Commenting on them The Lancet[1] said: "It has long been recognised that the welfare provisions in British universities are in many ways inadequate, and that the health and sickness of students have had too little attention." This statement is unquestionably true; but later in the same article it is said that "Of recent years a few British universities and several medical schools have started partial services; but a fully operative service, making proper provision for periodic health examination and care of sickness, has yet to be announced." This demands some modification. An effective and in many ways a comprehensive medical service has been in operation at the University of Edinburgh for 18 years, and now occupies an accepted and acceptable place in the life of the Edinburgh student community. Since this was not mentioned either at the conference or in the papers already referred to, we thought that a short account of our experience and observations of its working might be of interest and of use to other institutions contemplating the foundation of such a service.

HISTORY

The pioneer advocate in this country of the protection and care of student health was the late Lord Constable, whose report on the social and physical amenities of student life at the University of Edinburgh was published in 1926. The substance of this report was largely implemented by the dynamic effort and intense interest of the late J. J. M. Shaw, F.R.C.S., and a new era of student welfare was started in the University of Edinburgh at the beginning of the winter session of 1929, when a department of physical education was formed under the directorship of Colonel R. B. Campbell, O.B.E., D.S.O., M.A.

The activities of this department included a scheme for the medical examination of students by two part-time male physicians for the men and a part-time lady physician for the women. It was decided at the outset that this medical examination should be purely voluntary, and, apart from bringing it to the notice of undergraduates, the authors of the scheme made no attempt to persuade anyone to appear for examination. It was thought that, when the value of the examination came to be understood and appreciated, the numbers requesting it would gradually increase, until eventually all students would accept it as a matter of course.

Besides the routine examinations, arrangements were made for sick students to be attended in their lodgings or hostels and, where necessary, to be referred for admission to the special students' ward in the Royal Infirmary.

At its inception, the scheme was fortunate to have as principal medical officers Dr. J. K. Slater and Dr. Dorothea Walpole, and an account of the experience of the first nine years was published by Slater.[2] During this period an average of 459 students (383 men and 76 women) underwent routine medical examination each year.

In 1939 the wisdom and generosity of Sir Donald Pollock permitted a notable advance in the scope and quality of the physical education service of the university. By donating the commodious and well-equipped Pollock Institute of Physical Education he provided the organisation with two superb gymnasia, a fencing-salle, a boxing-ring, instructors' offices, changing-rooms, offices for the director of physical education, and facilities and premises for the medical branch of the service. During the war the scheme could not come to full fruition, but the care of student health was maintained: an average of 360 men and 50 women were examined each year, and sick students continued to obtain medical attention in their lodgings and at the Royal Infirmary.

At the end of the war Colonel C. M. Usher, D.S.O., O.B.E., succeeded Colonel Campbell as director of the department of physical education, and a department of student welfare services was inaugurated, with Major C. H. J. Deighton as director.[3]

OBJECTS OF THE MEDICAL SERVICE

The authors of the scheme have had six principal objects in mind since the inception of the medical service:

(1) To obtain by routine medical examination at the beginning of the first academic year an accurate estimate of the physical state of each student entering the university.

(2) To advise and treat students found at the routine examination to be not wholly fit.

(3) To encourage students to undergo routine medical examination in each of their undergraduate years.

(4) To create an efficient consultative and domiciliary medical service to advise and treat students requiring medical attention.

(5) To interest the students in the importance of phy education and recreation as an essential part of their curriculum.

(6) To obtain data concerning the health of the and to assess the effects of the various strains and (mental, environmental, nutritional, &c.) to which they subjected.

ROUTINE MEDICAL EXAMINATION

Under the present arrangement every student on matriculation is expressly invited to undergo routine medical examination and radiological examination (min radiography) of the chest. Any student on subsequent matriculation may request re-examination. Radiological examinations are carried out on 75 men and 48 women students each Wednesday afternoon or Saturday morning. The following week, when the reports of these examinations are available, a clinical examination is conducted at the medical department of the Pollock Institute, or at the Women's Union. Fifteen male students are examined each evening and the findings recorded on special cards. In this way two part-time physicians have been able to carry out 1000 routine examinations on men students, as well as to give service to rather more than 600 students requiring advice and treatment, in an academic year. For women students there are three part-time physicians: the additional physician has been accustomed to look after the health of the students in some of the women students' hostels.

At the clinical examination students are grouped as follows:

(1) *Healthy Robust Students.*—Each student in this group is assured that he is physically fit and is instructed in the value of maintaining the highest standard of physical and mental fitness. He is encouraged to take part in the various athletic and social activities of the university. In this way a close liaison is maintained with the work of the department of physical education, and many recruits are obtained for membership of the athletic clubs and for gymnasium recreation.

(2) *Students with Minor Physical Defects.*—Minor physical ailments, such as defects of posture, skin disorders, foot deformities, &c., are found in about 27% of students. Remedial measures for these are instituted at once, or the student is advised to attend the consulting session for sick students.

(3) *Students with Major Physical Defects.*—Nearly 2% of students are found to have some major physical disorder, such as diabetes, pulmonary tuberculosis, or cardiac disease. Under such circumstances a detailed investigation is made in the students' ward, and consideration is then given to the advisability of the student continuing his studies in his chosen faculty.

(4) *Students with Psychological Difficulties.*—Anxiety states are encountered in 7% of students examined. Many anxieties can be removed at this interview. As a result of the close liaison with the department of student welfare services, the student who is unsettled through domestic or social difficulties—e.g., unsuitable lodgings—can be given appropriate assistance. Those in which the psychological problems are more deep-rooted are referred to the psychiatrist at Jordanburn Nerve Hospital and Psychological Institute.

COMPULSION

Compulsory medical examination of all students has been advocated in some quarters, and some of the representatives of the British Medical Students Association have been agitating for the adoption of this measure. As medical examiners, however, we would be most unwilling to examine any person who does not wish it, and, in relation to university undergraduates, any question of compulsion in this respect becomes all the more distasteful. It is worth while recalling Sir Walter Raleigh's words when war was made the excuse for imposing restrictions at Oxford: "A certain amount of freedom to go wrong is essential in a university where men are *learning not to* obey but to choose."

We are satisfied with the results afforded by the voluntary system in use here. In the academic year

---

[2] Slater, J. K. *Edinb. med. J.* 1940, 47, 32.

[3] A diagram illustrating its present organisation may be had on application to THE LANCET office.

946–47 1536 invitations for routine medical examination were sent out, and 1140 students accepted. It seems ikely that by carrying out the examinations at appointed imes which are convenient for the individual students we could ensure that almost 100% of students would voluntarily present themselves for examination.

CONSULTATIVE AND DOMICILIARY MEDICAL SERVICE

Separate consulting-rooms are available for men and women students—for men in the medical department of the Pollock Institute of Physical Education, and for women at the Women's Union. Any student requiring medical advice or treatment may attend at the consulting sessions, which are conducted during an afternoon hour on Mondays, Wednesdays, and Fridays. Records of each student are kept.

Any student requiring medical attention in lodgings or in a hostel notifies the director of student welfare services and is thereafter visited and treated. If conditions are unsuitable for proper care and nursing, or if the disorder warrants admission to hospital, the student is transferred to the students' ward. Between May 1 and Dec. 15, 1947, 456 men and 128 women students used this service. The disabilities encountered were as follows:

	Male	*Female*	*Total*	*Percentage*
Skin diseases	65	19	84	14·2
Functional disorders ..	69	11	80	13 7
Respiratory	61	13	74	12·7
Ear, nose, and throat ..	47	19	66	11·3
Traumatic and orthopædic	62	3	65	11·1
Ophthalmological ..	32	14	46	7·9
Alimentary	28	11	39	6·7
Genito-urinary	22	7	29	5 0
Minor surgery	21	7	28	4·8
Psychological	15	4	19	3·2
Dental	16	1	17	2·9
Chilblains	0	10	10	1·7
Rheumatic	4	3	7	1·2
Pulmonary tuberculosis ..	6	0	6	1·0
Endocrine	1	3	4	0·7
Blood diseases	1	3	4	0·7
Infectious diseases ..	3	0	3	0·5
Vitamin deficiency ..	2	0	2	0·3
Glandular tuberculosis ..	1	0	1	0·2
Total ..	456	128	584	

The high incidence of functional disorders is no doubt a reflection on the somewhat unnatural existence of university students. Considerable patience is required in dealing with this type of disorder, and every facility must be available for excluding organic disease as a basis for symptoms.

HOSPITAL FACILITIES

For many years the Edinburgh Royal Infirmary has made special provision for the treatment of undergraduates in a unit consisting of four small wards to accommodate a total of 10 students. With the increased number of undergraduates at the university there are occasions, especially at the end of term, when there are insufficient beds to cope with the demands. This unit has accommodated an average of 181 students each year. From our experience it seems necessary to have 5 beds per 1000 students to meet the demands for admission to hospital.

From Jan. 1, 1934, to Jan. 1, 1948, 2538 students (1912 men and 626 women) have been admitted to this unit with the following ailments:

		Cases
Boils, carbuncles, cellulitis, &c. ..		132
C.N.S.:	Psychological ..	28
	Degenerative ..	9
	Inflammatory ..	26
Circulatory:	Vasomotor ..	7
	Varicose veins, hæmorrhoids, &c. ..	32
	Thrombophlebitis ..	7
	Rheumatic carditis ..	12
Dental ..		46
Dermatological:	Septic infections ..	24
	Dermatitis ..	17
Endocrine:	Diabetes ..	12
	Thyroid disorders ..	7
Ear, nose, and throat:	Tonsillitis ..	93
	Sinusitis (no operation) ..	30
	Otitis ..	28
	Tonsillectomy ..	358
	Submucous resection ..	118
	Antrostomy, mastoidectomy, &c.	65
Gastro-intestinal:	Gastritis, gastro-enteritis, &c. ..	67
	Peptic ulcer (including operations) ..	57
	Appendicectomy ..	291
	Other operations ..	8
	Infective hepatitis ..	35
	Amœbiasis ..	4
Gynæcological ..		49
Infectious diseases ..		21
Miscellaneous ..		193
Neoplastic (benign and malignant) ..		24
Ophthalmological ..		12
Respiratory:	Acute coryza ..	6
	Influenza ..	37
	Bronchitis ..	42
	Pneumonia ..	35
	Asthma ..	15
	Pleurisy ..	17
	Pulmonary tuberculosis ..	21
Rheumatic disorders ..		38
Urogenital tract ..		114
Traumatic:	Soft tissue ..	247
	Fracture ..	85
Herniotomy ..		64

These figures show that the bulk of the work is surgical, and, of the special departments, the ear, nose, and throat greatly exceeds all others in the number of demands on its services. Among the 193 "miscellaneous disorders" there were 22 cases of pilonidal sinus (15 males and 7 females). Among the 247 cases of trauma affecting soft tissues, no less than 49 required meniscectomy. Almost all the traumatic cases resulted from athletic pursuits. A total of 332 cases under this heading is a comparatively large figure when one considers that not more than 25% of students of this university take part in athletics. The services of all members of the honorary staff of the hospital are available to students. Besides the inpatients in this ward, many students are investigated as outpatients.

PULMONARY TUBERCULOSIS

Students found to have pulmonary tuberculosis are referred for review to the professor of tuberculosis, but we have usually encountered difficulty in arranging their correct disposal. The local authority of the student's home usually refuses to accept responsibility, which legally devolves on the tuberculosis officer of the area in which the patient is residing when the infection is recognised. The M.O.H. for Edinburgh has accepted this responsibility, but beds are seldom available in the town sanatoria for such students. The accommodation of tuberculous students is part of the national problem of the shortage of tuberculosis beds and trained nurses. It would be preferable if there existed in this country a small sanatorium attached to the professorial unit of some university for treatment of tuberculous undergraduates from all universities. In such circumstances facilities could be developed for the continuation of studies.

FUTURE DEVELOPMENTS

It seems likely that the introduction of the National Health Service may render necessary some modification of the student health service. In the light of our experience in the working of the Edinburgh service, however, we have come to accept certain principles which must be followed if the service is to be efficient, successful, and popular with the students:

(1) The student expects to get medical advice from physicians of recognised ability and standing. If this is not available, he will prefer to obtain medical services from practitioners outside a university medical service.

(2) The recognition of disease in its earliest stages during routine medical examination requires judgment based on medical erudition and wide clinical experience. It is a student *health* service that is required; therefore it is essential that disorders be recognised in the earliest

interest and of use to other institutions contemplating the foundation of such a service.

HISTORY

The pioneer advocate in this country of the protection and care of student health was the late Lord Constable, whose report on the social and physical amenities of student life at the University of Edinburgh was published in 1926. The substance of this report was largely implemented by the dynamic effort and intense interest of the late J. J. M. Shaw, F.R.C.S., and a new era of student welfare was started in the University of Edinburgh at the beginning of the winter session of 1929, when a department of physical education was formed under the directorship of Colonel R. B. Campbell, C.B.E., D.S.O., M.A.

The activities of this department included a scheme for the medical examination of students by two part-time male physicians for the men and a part-time lady physician for the women. It was decided at the outset that this medical examination should be purely voluntary, and, apart from bringing it to the notice of undergraduates, the authors of the scheme made no attempt to persuade anyone to appear for examination. It was thought that, when the value of the examination came to be understood and appreciated, the numbers requesting it would gradually increase, until eventually all students would accept it as a matter of course.

Besides the routine examinations, arrangements were made for sick students to be attended in their lodgings or hostels and, where necessary, to be referred for admission to the special students' ward in the Royal Infirmary.

At its inception, the scheme was fortunate to have as principal medical officers Dr. J. K. Slater and Dr. Dorothea Walpole, and an account of the experience of the first nine years was published by Slater.[2] During this period an average of 459 students (383 men and 76 women) underwent routine medical examination each year.

In 1939 the wisdom and generosity of Sir Donald Pollock permitted a notable advance in the scope and quality of the physical education service of the university. By donating the commodious and well-equipped Pollock Institute of Physical Education he provided the organisation with two superb gymnasia, a fencing-salle, a boxing-ring, instructors' offices, changing-rooms, offices for the director of physical education, and facilities and premises for the medical branch of the service. During the war the scheme could not come to full fruition, but the care of student health was maintained: an average of 360 men and 50 women were examined each year, and sick students continued to obtain medical attention in their lodgings and at the Royal Infirmary.

At the end of the war Colonel C. M. Usher, D.S.O., O.B.E., succeeded Colonel Campbell as director of the department of physical education, and a department of student welfare services was inaugurated, with Major C. H. J. Deighton as director.[3]

OBJECTS OF THE MEDICAL SERVICE

The authors of the scheme have had six principal objects in mind since the inception of the medical service:

(1) To obtain by routine medical examination at the beginning of the first academic year an accurate estimate of the physical state of each student entering the university.

(2) To advise and treat students found at the routine examination to be not wholly fit.

(3) To encourage students to undergo routine medical examination in each of their undergraduate years.

(4) To create an efficient consultative and domiciliary medical service to advise and treat students requiring medical attention.

(5) To interest the students in the importance of phy education and recreation as an essential part of their uni curriculum.

(6) To obtain data concerning the health of the and to assess the effects of the various strains and (mental, environmental, nutritional, &c.) to which they subjected.

ROUTINE MEDICAL EXAMINATION

Under the present arrangement every student on matriculation is expressly invited to undergo routine cal examination and radiological examination (mini radiography) of the chest. Any student on sub matriculation may request re-examination. Radiological examinations are carried out on 75 men and 48 women students each Wednesday afternoon or Saturday morning. The following week, when the reports of these examinations are available, a clinical examination is conducted at the medical department of the Pollock Institute, or at the Women's Union. Fifteen male students are examined each evening and the findings recorded on special cards. In this way two part-time physicians have been able to carry out 1000 routine examinations on men students, as well as to give service to rather more than 600 students requiring advice and treatment, in an academic year. For women students there are three part-time physicians: the additional physician has been accustomed to look after the health of the students in some of the women students' hostels.

At the clinical examination students are grouped as follows:

(1) *Healthy Robust Students.*—Each student in this group is assured that he is physically fit and is instructed in the value of maintaining the highest standard of physical and mental fitness. He is encouraged to take part in the various athletic and social activities of the university. In this way a close liaison is maintained with the work of the department of physical education, and many recruits are obtained for membership of the athletic clubs and for gymnasium recreation.

(2) *Students with Minor Physical Defects.*—Minor physical ailments, such as defects of posture, skin disorders, foot deformities, &c., are found in about 27% of students. Remedial measures for these are instituted at once, or the student is advised to attend the consulting session for sick students.

(3) *Students with Major Physical Defects.*—Nearly 2% of students are found to have some major physical dis such as diabetes, pulmonary tuberculosis, or cardiac dis Under such circumstances a detailed investigation is the students' ward, and consideration is then given to the advisability of the student continuing his studies in his chosen faculty.

(4) *Students with Psychological Difficulties.*—Anxiety states are encountered in 7% of students examined. Many anxieties can be removed at this interview. As a result of the close liaison with the department of student welfare services, the student who is unsettled through domestic or social difficulties—e.g., unsuitable lodgings—can be given appropriate assistance. Those in which the psychological problems are more deep-rooted are referred to the psychiatrist at Jordanburn Nerve Hospital and Psychological Institute.

COMPULSION

Compulsory medical examination of all students has been advocated in some quarters, and some of the representatives of the British Medical Students Association have been agitating for the adoption of this measure. As medical examiners, however, we would be most unwilling to examine any person who does not wish it, and, in relation to university undergraduates, any question of compulsion in this respect becomes all the more distasteful. It is worth while recalling Sir Walter Raleigh's words when war was made the excuse for imposing restrictions at Oxford: "A certain amount of freedom to go wrong is essential in a university where men are learning not to obey but to choose."

We are satisfied with the results afforded by the voluntary system in use here. In the academic year

---

[2] Slater, J. K. *Edinb. med. J.* 1940, 47, 32.

[3] A diagram illustrating its present organisation may be had on application to THE LANCET office.

946–47 1536 invitations for routine medical examination were sent out, and 1140 students accepted. It seems likely that by carrying out the examinations at appointed times which are convenient for the individual students we could ensure that almost 100% of students would voluntarily present themselves for examination.

CONSULTATIVE AND DOMICILIARY MEDICAL SERVICE

Separate consulting-rooms are available for men and women students—for men in the medical department of the Pollock Institute of Physical Education, and for women at the Women's Union. Any student requiring medical advice or treatment may attend at the consulting sessions, which are conducted during an afternoon hour on Mondays, Wednesdays, and Fridays. Records of each student are kept.

Any student requiring medical attention in lodgings or in a hostel notifies the director of student welfare services and is thereafter visited and treated. If conditions are unsuitable for proper care and nursing, or if the disorder warrants admission to hospital, the student is transferred to the students' ward. Between May 1 and Dec. 15, 1947, 456 men and 128 women students used this service. The disabilities encountered were as follows:

	Male	*Female*	*Total*	*Per-centage*
Skin diseases	65	19	84	14·2
Functional disorders	69	11	80	13·7
Respiratory	61	13	74	12·7
Ear, nose, and throat	47	19	66	11·3
Traumatic and orthopædic	62	3	65	11·1
Ophthalmological	32	14	46	7·9
Alimentary	28	11	39	6·7
Genito-urinary	22	7	29	5·0
Minor surgery	21	7	28	4·8
Psychological	15	4	19	3·2
Dental	16	1	17	2·9
Chilblains	0	10	10	1·7
Rheumatic	4	3	7	1·2
Pulmonary tuberculosis	6	0	6	1·0
Endocrine	1	3	4	0·7
Blood diseases	1	3	4	0·7
Infectious diseases	3	0	3	0·5
Vitamin deficiency	2	0	2	0·3
Glandular tuberculosis	1	0	1	0·2
Total	456	128	584	

The high incidence of functional disorders is no doubt a reflection on the somewhat unnatural existence of university students. Considerable patience is required in dealing with this type of disorder, and every facility must be available for excluding organic disease as a basis for symptoms.

HOSPITAL FACILITIES

For many years the Edinburgh Royal Infirmary has made special provision for the treatment of undergraduates in a unit consisting of four small wards to accommodate a total of 10 students. With the increased number of undergraduates at the university there are occasions, especially at the end of term, when there are insufficient beds to cope with the demands. This unit has accommodated an average of 181 students each year. From our experience it seems necessary to have 5 beds per 1000 students to meet the demands for admission to hospital.

From Jan. 1, 1934, to Jan. 1, 1948, 2538 students (1912 men and 626 women) have been admitted to this unit with the following ailments:

		Cases
Boils, carbuncles, cellulitis, &c.		132
C.N.S.:	Psychological	23
	Degenerative	9
	Inflammatory	26
Circulatory:	Vasomotor	7
	Varicose veins, hæmorrhoids, &c.	32
	Thrombophlebitis	7
	Rheumatic carditis	12
Dental		46
Dermatological:	Septic infections	24
	Dermatitis	17
Endocrine:	Diabetes	12
	Thyroid disorders	7
Ear, nose, and throat:	Tonsillitis	93
	Sinusitis (no operation)	30
	Otitis	28
	Tonsillectomy	358
	Submucous resection	118
	Antrostomy, mastoidectomy, &c.	65
Gastro-intestinal:	Gastritis, gastro-enteritis, &c.	67
	Peptic ulcer (including operations)	57
	Appendicectomy	291
	Other operations	8
	Infective hepatitis	35
	Amœbiasis	4
Gynæcological		49
Infectious diseases		21
Miscellaneous		193
Neoplastic (benign and malignant)		24
Ophthalmological		12
Respiratory:	Acute coryza	6
	Influenza	37
	Bronchitis	42
	Pneumonia	35
	Asthma	15
	Pleurisy	17
	Pulmonary tuberculosis	21
Rheumatic disorders		38
Urogenital tract		114
Traumatic:	Soft tissue	247
	Fracture	85
Herniotomy		64

These figures show that the bulk of the work is surgical, and, of the special departments, the ear, nose, and throat greatly exceeds all others in the number of demands on its services. Among the 193 "miscellaneous disorders" there were 22 cases of pilonidal sinus (15 males and 7 females). Among the 247 cases of trauma affecting soft tissues, no less than 49 required meniscectomy. Almost all the traumatic cases resulted from athletic pursuits. A total of 332 cases under this heading is a comparatively large figure when one considers that not more than 25% of students of this university take part in athletics. The services of all members of the honorary staff of the hospital are available to students. Besides the inpatients in this ward, many students are investigated as outpatients.

PULMONARY TUBERCULOSIS

Students found to have pulmonary tuberculosis are referred for review to the professor of tuberculosis, but we have usually encountered difficulty in arranging their correct disposal. The local authority of the student's home usually refuses to accept responsibility, which legally devolves on the tuberculosis officer of the area in which the patient is residing when the infection is recognised. The M.O.H. for Edinburgh has accepted this responsibility, but beds are seldom available in the town sanatoria for such students. The accommodation of tuberculous students is part of the national problem of the shortage of tuberculosis beds and trained nurses. It would be preferable if there existed in this country a small sanatorium attached to the professorial unit of some university for treatment of tuberculous undergraduates from all universities. In such circumstances facilities could be developed for the continuation of studies.

FUTURE DEVELOPMENTS

It seems likely that the introduction of the National Health Service may render necessary some modification of the student health service. In the light of our experience in the working of the Edinburgh service, however, we have come to accept certain principles which must be followed if the service is to be efficient, successful, and popular with the students:

(1) The student expects to get medical advice from physicians of recognised ability and standing. If this is not available, he will prefer to obtain medical services from practitioners outside a university medical service.

(2) The recognition of disease in its earliest stages during routine medical examination requires judgment based on medical erudition and wide clinical experience. It is a student *health* service that is required; therefore it is essential that disorders be recognised in the earliest

stages, when curative measures are most likely to be effective.

(3) There is always a small proportion of the students with some acute or potentially serious illness. It is unquestionably the university's responsibility to ensure that the quality of the medical advice available on these occasions is of the highest standard, and that the student is not exposed to any risk resulting from inexperience of the medical staff. These considerations have, until now, been fulfilled by the appointment (on a part-time basis) of physicians on the staff of the teaching hospital, who are either Fellows or Members of the Royal College of Physicians of Edinburgh. Since the range of clinical material arising from morbidity among the students is comparatively restricted, the physicians doing the work of this service should have access to wider fields of clinical medical practice if they are to maintain a high standard of clinical efficiency. For this reason the appointment of part-time physicians must be strongly recommended.

(4) An important feature of our service hitherto has been the close cooperation between the medical staff and the directors of physical education and of student welfare. It is therefore an advantage if the members of the medical staff carrying out routine medical examinations have a keen interest in physical culture, athletics, social welfare, and the theme of positive health.

(5) A part-time psychiatrist who would conduct sessions at the medical centre would be of considerable advantage.

(6) A medical officer interested in the social aspects of student life and working in close liaison with the department of public health and social medicine could undertake sociological investigations and would have the opportunity of collecting data about the physical and mental aspects of student health from the students and from his clinical colleagues.

CONCLUSION

The University of Edinburgh has conducted a comprehensive student medical service for nearly 20 years.

A brief account is given of its history, the scope of the work it undertakes, and the possible developments.

ACUTE BENIGN DRY PLEURISY

SIX CASES IN A HOSPITAL STAFF

J. D. GRAY
M.D. McGill, D.C.P.
PATHOLOGIST,

F. STEPHEN CARTER
M.B. Camb., D.C.H.
REGISTRAR

BELGRAVE HOSPITAL FOR CHILDREN, LONDON

UNDER the name, acute benign dry pleurisy, Scadding (1946) described 20 cases of a syndrome which in some ways resembled Bornholm disease but differed from it in that gross dry pleurisy was present. The cases were all seen in the Suez Canal area. In England Williamson (1924) described an outbreak of a similar condition in a London children's hospital; Lloyd (1924) reported 5 cases among the nurses of The Hospital for Sick Children, Great Ormond Street; and Attlee et al. (1924) reported 48 cases, 17 of them with a pleural rub, in a boy's school.

The disease reported by Pickles (1933), Carter (1933), and Howard (1938) more closely resembles Bornholm disease and can therefore be excluded from a discussion of the illness described by Scadding.

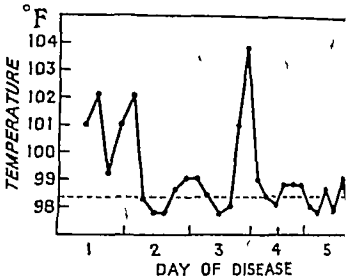
So far as can be gathered from published reports, England seems to have been free from acute benign dry pleurisy for twenty-three years. Since, however, an outbreak occurred among 5 nurses and 1 ward maid at this hospital, it was felt necessary to report it so that the existence of this disease may not be forgotten.

The first case was seen on Sept. 15, 1947, the second Sept. 16, 2 on Sept. 18, and the final 2 on Sept. 20. patients came from various wards in the hospital, no common point of association was discovered. duration of the illness from reporting sick to return work varied from seven to fourteen days, with an a of nine days.

SYMPTOMS

The following account of the subjective sensat experienced was written by one of the nurses:

Sept. 17.—Awoke with headache and stiff feeling waist up—chest and back. It gradually got worse all and developed into a severe stabbing pain which seemed to get tighter until it hurt to breathe. The pain was right round the waist and up the centre to about the 5th rib. Felt frozen and hot in turns, splitting head, eyes smarted, and temperature up 101°F. Did not sleep very well. Perspired a lot in the night.



Typical temperature chart in acute ben dry pleurisy.

Sept. 18.—Felt well. Very little pain; appetite goo Did not sleep well.

Sept. 19.—Bad headache in morning. Pains a bit wors mostly at left side, then felt O.K. till evening. Pains wors beginning over left bottom ribs and extending round to righ back. Felt cold and shivery, hot, and dry. Eyes smarted T. 103°F. Felt like death. At 2 A.M. T. 99°F. Felt col and clammy and much better.

Sept. 20.—Felt O.K. in morning. In afternoon pa gradually got worse (after laughing a bit)—still in the sam place—until it felt as if all the muscles were squeezing inwar and upwards until I had difficulty in breathing for about hour. I seemed to catch my breath as if I were tearing som thing in my chest. It was impossible to cough, sneeze, yawn during the pain. If I turned from side to side I felt if I wanted to cough. The pain always went to the si I lay on.

Sept. 21.—Did not feel too bad in morning, but at midd had a severe headache and nausea. Felt "all-in" by evenin Vomited once. Slept fairly well.

Sept. 22.—Felt O.K. less pain.

Sept. 23.—Pain worse—higher up in chest, as on first da

Sept. 24.—Pain worse—more localised across top of chest first two or three pairs of ribs. In evening breathing diffic and very painful—probably due to a good deal of laughin again. Slept very well.

Sept. 25.—Woke feeling as if someone had been jump on my chest all night. All front and back sore when breathed. Pain gradually became localised to front of ch as yesterday, and right side just outside about the 6th r and also across back above waist from right side to just pa spine. Had sick headache and pain behind eyes. A slight exertion seemed to make pain worse, especially laught

SIGNS

In 3 of the 6 cases there was dry pleurisy, one produci a palpable rub. In 5 of the cases the temperature cha was almost identical in shape (see figure). The pulse-ra was in proportion to the temperature. In 3 cases the was a mild pharyngitis at the onset of the illness; 2 of these a pleural rub subsequently developed. I case *Strep. hæmolyticus* was isolated from the thro swab. In 1 case there was an area of hyperæsthe over the left chest. All 6 patients had their chests radi graphed early and late in the illness. Changes we not seen.

LABORATORY FINDINGS

Erythrocyte-sedimentation rates taken at week intervals from the start of the illness were normal. 4 cases a full blood-count showed no change. In cases there was a neutropenia on the day of admissio to the ward: 3430 white cells per c.mm. (neutrophils 34%) in one case: and 3750 white cells per c.mm. (neutrophils 48%) in the other. Ten days later both counts were normal.

DISCUSSION

This disease is interesting for several reasons. First, the previous epidemics in this country have, with one exception, occurred in children's hospitals—the exception was a boy's school. Secondly, as Scadding (1946) has pointed out, its clinical importance lies not in the illness itself but in distinguishing it from more serious disorders. An isolated case to the unwary might possibly suggest the onset of a tuberculous pleurisy or a pneumonia. Occasionally it is associated with an eosinophilia which, in combination with the muscle pain, suggests trichiniasis. Lastly, the relationship between Bornholm disease and Scadding's acute benign dry pleurisy requires consideration. Except for the high incidence of pleurisy, in one of them, both diseases are identical. Bornholm disease is known at times to produce transient inflammation in other serous sacs, such as the pericardium.

The information available suggests that acute benign dry pleurisy is a manifestation of Bornholm disease. Therefore a better name for it might be "Bornholm disease with pleurisy."

PREPARATION OF STREPTOCOCCAL EXTRACTS FOR LANCEFIELD GROUPING

W. R. MAXTED
F.I.M.L.T.
Technical Research Assistant, Central Public Health Laboratory, Colindale

THE methods of extracting polysaccharide for grouping β-hæmolytic streptococci, recommended by Lancefield (1933) and Fuller (1938), have proved very satisfactory but somewhat laborious and exacting when large numbers of strains have to be tested. The chance discovery of a streptomyces that produces a potent proteolytic substance capable of liberating the C substance from β-hæmolytic streptococci suggested a simple method for the preparation of extracts for Lancefield grouping.

METHODS

Preparation of Proteolytic Factor.—Spores from the strain of *Streptomyces albus* were suspended in saline and a small volume of suspension run over the surface of an agar medium in Roux bottles. The medium contained 'Eupeptone no. 2' 0·5%, 'Yeastrel' 0·3%, dibasic sodium phosphate 0·2%, glucose 0·2%, Fildes's extract 2·5%, and shred agar 1·25%. Cultures were incubated at 30–37°C for 4–6 days. The bottles were removed to a −10°C refrigerator for 12 hours and the frozen cultures then allowed to thaw out. By this method * the bulk of the fluid in the medium was recovered from the agar gel. This fluid contained the products of the organism, one of which is an active lytic agent presumably an enzyme. The fluid, which had an initial pH of 9·0, was adjusted to pH 7·5 by adding hydrochloric acid, and was ready for use after filtration through a Seitz pad. To test the effectiveness of the filtrate, 0·1 ml. of a heavy suspension (about 4000 million organisms per ml.) of heat-killed group A streptococci was added to 0·4 ml. of the proteolytic solution in a 3 in. × ½ in. tube and the mixture was placed in a water bath at 50°C. A tube containing heated enzyme solution plus streptococcal suspension acted as control. An active lytic solution completely lysed this streptococcal suspension in approximately 30 minutes.

It will be seen that the production of the enzyme solution is simple. Its potency is high and varies little with the temperature of incubation of the streptomyces culture within the range 30–37°C. The inclusion of Fildes's extract made a notable difference to the yield of enzyme. The solution is active over the pH range 9·6–5·6; it keeps well when stored in the cold with 0·5% phenol as a preservative. At least two oxidising agents and a number of reducing agents inactivate the enzyme.

Cultures of Hæmolytic Streptococci.—Strains submitted, whether from throat swabs or subcultures of strains already isolated, were spread on segments of a blood-agar plate and incubated overnight.

Preparation of Streptococcal Grouping Extracts.—Into each of a series of Dreyer's tubes was run 0·25 ml. of enzyme solution and a loopful of growth taken up from the 18 hr. blood-agar culture was suspended in it. The tubes were placed in a water bath at 50°C and left until quite clear (approximately 1½ hr.). This clear solution was used to carry out the usual precipitin ring tests against the various group antisera, which were prepared in this laboratory, and results were read after 15 minutes.

RESULTS

The table shows the results obtained in the examination of 177 strains in parallel with the Lancefield or Fuller methods. With extracts made with the proteolytic solution positive reactions appeared as quickly and were at least as clear-cut as those obtained with Lancefield or Fuller methods. In fact, more positive reactions were obtained by the enzyme method than by the Lancefield or Fuller method with strains belonging to groups A, C, and G. The failures with the latter methods were probably due to slight technical errors in the preparation of the extracts, since those strains which gave positive results with the enzyme method alone subsequently gave positive reactions with fresh extracts prepared by Fuller's method. Stock cultures of most of the other Lancefield group strains have been tested: there has been no evidence of destruction of the group polysaccharide by the lytic agent and no non-specific reactions have been observed.

Some strains of streptococci, when used as living suspensions, were resistant to the lytic action of the extract. Among strains so far tested, groups D and K and many α-hæmolytic streptococci show this tendency. In general the resistant strains appeared to be largely streptococci showing α-hæmolysis on blood agar, and a number of others showing some β-hæmolysis but not yielding a soluble hæmolysin. The possibility of using this phenomenon for distinguishing hæmolytic from

Totals	177	132	115

---

[*] This method was suggested to me by Mr. G. V. Heimer, who uses it to extract and concentrate staphylococcal bacteriophage.

non-hæmolytic strains is under investigation. For the preparation of extracts of such resistant strains, the colonies are first suspended in a drop of saline in the Dreyer's tube, the tubes are immersed in boiling water for 3–4 minutes and cooled; and the enzyme solution is then added. Lysis takes place within a reasonable time.

DISCUSSION

That some streptomyces produce lytic substances is common knowledge, but their action in liberating C substances from hæmolytic streptococci does not appear to have been described previously. The present method, which utilises this property, has proved successful for the identification of members of Lancefield groups A, B, C, and G during large-scale streptococcal surveys and routine grouping of strains from acute cases.

Clearly a greater and more varied collection of strains must be tested by this method in parallel with the Lancefield or Fuller method before its reliability can be assessed. Though it is not claimed that the method gives better extracts than the two in general use, it does reduce the labour and care required by eliminating the need for centrifugation and neutralisation which are so time-consuming. The resistance of certain strains to lysis is no doubt a disadvantage in some cases, but in clinical and public-health laboratories the main need is to identify streptococci of groups A, B, C, and G, and so far all strains belonging to these groups have been lysed and successfully grouped by this method.

SUMMARY

A simple method of producing a strong proteolytic factor—presumably an enzyme—from a streptomyces is described. Preliminary investigations show that it can be used for extracting the polysaccharide C substance from streptococci of groups A, B, C, and G, and that for this purpose it is quicker than either the Lancefield or the Fuller method of group determination.

RENAL TUMOUR AND PERSISTENT FEVER

REPORT OF A CASE

L. ZÁDOR
M.D.
ASSISTANT PROFESSOR IN THE UNIVERSITY CLINIC OF UROLOGY, BUDAPEST

In view of the report by Catlin et al.[1] of two cases in which the presenting symptom of hypernephroma was long-continued fever, the following case is of interest.

A man, aged 45, had had “influenza” a year previously. On the first day his temperature had reached 102°F, and in the following week 99–99·5°F, but evening pyrexia had persisted for the whole year, accompanied by slight rigors. The patient had been able to get about and continue his occupation. He had not had any pain or any urinary trouble, and repeated examinations of urine had not disclosed any abnormality. Extraction of four diseased teeth and tonsillectomy for chronic tonsillitis had not cured pyrexia. The patient had gradually become anæmic and weak.

His doctor, suspecting intoxication by hair-dye used in the patient's occupation had injected sodium thiosulphate without effect; in fact the temperature had risen above 100·5°F for a few days. Malaria had been excluded but *Staph. aureus* had been cultured from the blood. For this reason penicillin treatment, already started, had been continued to a total of 33,000,000 units.

Because of progressive anæmia several blood-transfusions had been given. The temperature had not fallen but had become intermittent, and on the days of remission pus appeared in urine. The patient was therefore admitte hospital.

On admission the patient was emaciated, with gr skin, and was unable to walk. The kidneys were not palp the left costovertebral angle was full; there was no tende in the lumbar regions. A varicocele was present on th side.

Urine: traces of albumin; pus abundant, leucocyte occasional erythrocytes and granular casts; staphyloc no tubercle bacilli.

Blood: red cells 2,440,000 per c.mm., Hb 40%; white 8800 per c.mm. Blood-pressure 130/65 mm. Hg; erythro sedimentation rate 110 mm. in 1 hr.

Chromocystoscopy: normal vesical mucosa and ure orifices; intravenous indigo appeared after 4 min. on right side, but none had appeared after 25 min. on the left

Ureteric catheterisation was easy on the right side but diff on the left; the urinary sediment showed no abnormaliti

Radiography.—Left kidney irregular and enlarged later Retrograde pyelography showed renal pelvis and one c greatly dilated and pelvis displaced caudally; other ca compressed; ureter one finger-breadth wide.

From these findings a renal tumour was diagnosed operation was decided on.

Nephrectomy.—A tumour about 6 in. in diameter removed, which on histological examination proved to hypernephroma.

Progress.—Penicillin 200,000 units daily was given five days. After the wound had healed, radiotherapy applied. The patient's general condition quickly impro his pyrexia disappeared on the third day, and he was charged from hospital, with his wound healed, on the n day. Three months later he was in good condition, co walk, and had begun to put on weight.

DISCUSSION

During his illness this patient had no pain and urinary trouble; nor did he observe any tumour in abdomen. His only symptoms were progressive ema tion, anorexia, and evening pyrexia, which remai unexplained for a year. The pyrexia was mainta by the production of toxins by necrosis and infectio the tumour. No functioning renal parenchyma found. The ureter was completely occluded by ma from the necrotic tumour, and only in the last few w did pus appear in the urine.

Israel[2] called attention to the fact that fever often the only symptom of a malignant neopl Babics[3] also emphasises the importance of pyr He reported the case of a man of 43 whose first and symptom of renal tumour was evening pyrexia.

The present case lacked three cardinal sympto hæmaturia, palpable enlargement of the kidney, pain. Occlusion of the ureter prevented hæmatu The fact that the tumour occupied the upper pol the kidney made palpation difficult; tumours in lower pole are easily palpated. On radiography diaphragm usually shows a limited action owing fixation of the tumour to the diaphragm. Pain, w present, is usually dull, but sometimes, if the ur is occluded by clots, it resembles colic due to renal st It may then be differentiated from colic due to stone the fact that bleeding precedes the pain.

The secondary anæmia was imputed to the supp septic focus.

Varicocele due to compression of the spermatic v is often helpful in the diagnosis. In a late stage dil tion of the collateral veins on the abdominal wall be observed.

Renal tumours on the left side are often conf with splenomegaly; but careful urological examina should establish the correct diagnosis.

Medical Societies

INTERNATIONAL CONGRESS OF PSYCHOLOGY

Prefrontal Leucotomy

THE symposium on prefrontal leucotomy at the 12th International Congress at Edinburgh on July 26 was to have been opened by Prof. **Kurt Goldstein**, of New York, who for many years has worked on the psychological problems of frontal-lobe function. He was prevented by illness from being present; but his paper, when read towards the end of the meeting, formed a philosophical complement to the more clinical approach of the earlier contributors. Professor Goldstein considered the main frontal-lobe defect to be the loss of what he called the "abstract attitude" towards reality; he described at length this attitude and the consequence of its loss. The attitude was the essence of man's nature, and he considered it doubtful whether it could be restored by training after it had been altered by leucotomy.

Dr. **Erwin Stengel** mentioned the empirical and drastic nature of the treatment. He pointed out that after operation it was necessary to make a distinction between changes in the symptoms of the illness and changes in the personality of the individual. Some changes, such as those concerned with energy and libido, were really quantitative although at first sight they appeared to be qualitative. As a therapy, leucotomy had its most marked effect on states of abnormal depression. The effect on schizophrenia and paranoid states was less impressive, but even here alleviation of tension in chronic cases often transformed life into one of happiness. The question of the effect of the operation on periodicity and recurrence had not yet been answered with certainty. In his experience some patients with these features were free from recurrence for longer periods after operation. Others had milder attacks and in a few there were mitigated fragments of an attack. The extent of change in personality and the individual features found depended mainly on the original personality. Not every person in possession of undivided frontal lobes was easy to live with, tactful, considerate, or deeply religious. Dr. Stengel expressed the opinion that a team of expert research-workers given the task of tracing an unknown number of leucotomy cases out of 500 ordinary people would fail to identify every such case and would find some post-leucotomy features in many who had never been near a psychiatrist. It could be concluded that quite a few ordinary people were labouring under a frontal-lobe deficit. While this emphasised our ignorance it also brought the challenge —what can we do to mobilise the dormant riches of our brains?

Dr. **G. W. Mackay** dealt with the results of leucotomy in a small series of cases in an institution for criminal mental defectives. The patients were all delinquent in varying degree, and of low intelligence; they were suffering from psychopathic states and manifest gross impulsive, violent, and self-destructive behaviour. The postoperative period ranged from six to eighteen months. The best results were obtained in cases uncomplicated by physical disorders such as epilepsy or a postencephalitic state. Of the 9 patients in this group 6 were regarded as recovered or much improved and several could be discharged from the institution. In addition, 2 patients of this type and 3 epileptic- or postencephalitic cases derived some benefit. These results were strikingly illustrated by case-histories. The speaker commented that while it had been said that after leucotomy people lost their belief in religion, regarding these defectives one would rather say that the operation had killed the devil.

Prof. **Geoffrey Jefferson**, F.R.S., was also unable to attend, but his contribution was read in his absence. From his own early work on lobectomy the writer had drawn certain conclusions, the first of which was that the frontal lobes could not be regarded, either singly or together, as the organ of the mind. Secondly, even if the total behaviour of the individual were grossly disturbed, he would, with a successful operation, be restored to normality by unilateral lobectomy. Some inferences followed. Frontal-lobe tissue was not charged very highly with function; improvement was due to disembarrassment of the rest of the brain. The behaviour of the individual depended on his fundamental personality. Permanent alterations in personality occurred only if the opposite lobe was damaged as well, if the tumour extended elsewhere, or if the whole brain had been damaged by previous high pressure. There was the strongest objection to simplifying or codifying behaviour after leucotomy. In his experience those patients did best who before becoming mentally deranged had had time to develop their personality. With the sole exception of incontinence during consciousness, all the aberrations found after leucotomy could be seen with tumours elsewhere in the brain provided the intracranial pressure was raised. Leucotomy did much to make patients useful members of society but the terms "improvement" and "recovery" should be used with caution.

Dr. **Alfred Meyer** gave an account of the anatomical and pathological aspects of leucotomy investigated at the Maudsley Hospital, where more than 90 brains from patients dying some time after the operation had been examined. In those patients who had survived upwards of six months after operation full microscopic examination by serial sections had been carried out and the connexions of the frontal lobes with the thalamus had been studied. Variability of the site of the cut was still an impressive finding. With a varying cut we were studying the effects of very different frontal lesions. Dr. Meyer found it difficult to believe, as Hebb had inferred, that personality changes after operation were due rather to irritation of the surrounding tissues than to severance of the prefrontal fibres. Postoperative changes also depended on the number of segments of the frontal white matter involved. He demonstrated an ingenious method of classifying the difference in cut according to the number of segments involved in the lesion, and thus correlated the lesion with the clinical result. Concerning the plane of the cut it could be said that cases that did badly and died within six months of operation usually had a posterior cut. The degree of personality change correlated roughly with the number of fibres severed.

Dr. **M. A. Partridge** described observations made on 57 patients suffering from affective disorders operated on by Mr. Wylie McKissock and examined at intervals of six and twelve months after leucotomy. The preoperative prognosis was poor or hopeless in all but 5 cases. Altogether 50 patients were discharged from hospital, but of these 7 relapsed. Of the 43 patients at home the great majority resumed their former functions and proved to be as efficient in their work as before their illness. Every patient showed some frontal-lobe deficit at some time. Lowering of affect and activity facilitated by a lack of restraint were the commonest findings. Most patients could conceal their defects for a short time and in front of strangers. With the passage of time improvement took place.

Dr. **W. Mayer-Gross** reported on three further studies made on the material of the Crichton Royal. The first was concerned with the so-called failures of the operation—the 68 patients who remained in hospital. The second series of observations concerned 52 patients who had been operated on by a modified technique aiming at isolation of the orbital areas only. The third investigation dealt with 11 patients and represented the follow-up of cases of periodic psychoses (periodic catatonics and manic-depressives). In the light of this material the theory that improvement was due to the production of frontal-lobe symptoms was tested. It was found that as well as cancelling out the psychosis by the production of frontal-deficiency signs, the operation by itself abolished certain undesirable psychotic features. This was particularly evident in the periodic cases where in 8 of 11 patients periodicity disappeared; while in the remaining 3 it was modified.

Post-leucotomy personality change from the point of view of a non-medical psychologist was dealt with by Mrs. A. PETRIE, who described differences found in 20 patients tested before and two to three months after operation. These subjects, suffering from severe neurosis, were accessible to a battery of tests of cognition and temperament. Findings included a shift away from neurotic introversion and a decrease in intelligence. In the post-leucotomy patient there was reduced suggestibility and a smoother work-curve. He paid more attention to speed and less to accuracy than before operation. He blamed himself less, and while living less in the past he looked more hopefully to the future. His rote memory was impaired and there was some loss of verbal ability. Learning was more difficult, but routine tasks were more easily performed. The patient was less distractible. A frequent additional factor was loss in the finer distinctions of language. Common words were misused and new words formed.

Sir DAVID HENDERSON, who was in the chair, emphasised that leucotomy should be regarded as an operation of last resort. He drew a parallel between the effect of leucotomy and the effect of the shock therapies on cases of periodic psychosis. He stressed the importance of neurological and pathological investigations, and suggested that the pathological findings described cast some doubt on the adequacy of the "blind" operative procedure in use at present.

Reviews of Books

Manual of Leprosy

ERNEST MUIR, M.D., F.R.C.S.E., medical adviser, British Empire Leprosy Relief Association. Edinburgh: E. & S. Livingstone. 1948. Pp. 208. 17*s.* 6*d.*

DESCRIBED as a small book for doctors, nurses, and lay workers, this manual says little about the history, distribution, epidemiology, and bacteriology of leprosy, its emphasis being rather on the clinical sections. It includes a simple description of prophylactic measures.

An account is given of tissue reaction and resistance and the technique of the lepromin test. The South American classification, based on histological changes, has been adopted in place of the Cairo clinical one: this will be of value to experts with time and facilities for microscopical examinations in all doubtful cases, but will present difficulties to the more numerous workers who have to base their diagnosis on clinical appearances. Clinical description on the new lines is the most valuable part of the book. Clinical and bacteriological examinations are adequately described, and prognosis discussed, stress being laid on the value of the lepromin test. Four short chapters on treatment are perhaps less satisfactory. Injections of hydnocarpus oil and esters are advised, on the usual lines, but no mention is made of intramuscular injections of sodium hydnocarpate, still regarded by some as the most active of such preparations against leprosy. The value of sulphones in lepromatous cases is brought out, and promising preliminary results are reported with the newer sulphetrone preparation in Nigeria.

Osteotomy of the Long Bones

HENRY MILCH, M.D., consulting orthopædist, Maimonides Hospital, New York. Oxford: Blackwell Scientific Publications. 1948. Pp. 294. 35*s.*

THE earlier chapters deal with the simpler types of osteotomies of the various long bones in what seems excessive detail. Dr. Milch's insistence on accurate and finical descriptions tends at first to obscure rather than clarify; but as the chapters unfold, and as the crescendo—the complicated hip osteotomies—is reached, the reader is grateful, for he now finds himself familiar with clearly defined terms and conditions without which the more advanced mechanisms and descriptions would not be understood. Dr. Milch makes no attempt to simplify the theory behind his practice, and even a little elementary reading in long-forgotten school trigonometry books—which in itself provides something of the thrill of first looking into Hogben—may prove helpful. The final chapters amply reward the patient reader, for in them the various hip osteotomies are described in great and entrancing detail.

The early chapters deal with lineal, torsional, and angulational osteotomies of the shafts of the long bones, well established in practice, though the terms and descriptions may be novel. The wide scope of the later chapters embraces angulational and pelvic support osteotomies in the treatment of fractures, tubercle, and osteoarthritis of the hip. In orthopædics these methods are increasingly used, and—being simple in practice, though complicated in theory (as readers of this book will realise)—look like replacing more complicated procedures with grafts, screws, bolts, and nails.

Acute Bacterial Diseases: Their Diagnosis and Treatment

HARRY F. DOWLING, M.D., F.A.C.P., clinical professor of medicine, George Washington University. London and Philadelphia: W. B. Saunders. 1948. Pp. 465. 32*s.* 6*d.*

THOUGH this book is mainly the work of a professor of clinical medicine, two sections on the antibiotics have been written in collaboration with Dr. L. K. Sweet, a bacteriologist, and the sections on pertussis and diphtheria have been contributed by Dr. H. L. Hirsh, a pædiatrician who is also in charge of fever beds. Acute infectious processes of other than bacterial origin are only mentioned in connexion with differential [illegible] With the advent of the sulphonamides and antibi[illegible] clinical diagnosis of the acute bacterial diseases does not suffice: it is necessary, as Professor Dowling [illegible] out, to identify the causal organism if the appropriate chemotherapeutic agent is to be prescribed. Almost identical clinical syndromes may be caused by diverse organisms, some of which are amenable to chemotherapy while others are unaffected. The clinician must therefore use the laboratory fully at all stages of the illness.

The sections describing the sulphonamides and antibiotics are clear and informative; the account of streptomycin will be particularly acceptable to British physicians who are now assured of more adequate supplies. The diagnosis and treatment of specific coccal and bacillary infections and bacterial diseases in which exotoxins are a major factor are discussed in detail. A section on the acute forms of tuberculosis, apart from the conservative assessment of streptomycin therapy, serves to remind us that this infection must always be excluded in any obscure febrile illness. Typhoid fever is discussed separately, as the sole representative of "eberthella infections," while paratyphoid fever is included in a section on salmonella infections and briefly dismissed as a "typhoidal type of bacteræmia." Indeed, the author considers that the term "paratyphoid" should be discarded, since the causal organisms "represent a small part of the *Salmonellæ* all of which produce the same clinical picture"—a statement to which few will subscribe. *Eberthella typhosa*, too, is better known as *Salmonella typhi* in this country.

It is unfortunate that "membranous croup" is regarded as a synonym for diphtheria in general, though the term still lingers in this country as descriptive of the laryngeal form. As an account of current practice the book has great merits. It is lavishly illustrated.

THE LANCET

LONDON: SATURDAY, AUGUST 14, 1948

Smaller and Better Practices

WITH varying enthusiasm, more than 20,000 doctors have agreed to take part in providing a general-practitioner service for the nation. The Minister of Health, who can scarcely have relied on so large an initial response, may now believe the new service to be fairly launched. But we hope he will nevertheless consider carefully with his advisers how this favourable situation can be turned to advantage. To borrow a metaphor from one of Mr. BEVAN's other interests, any necessary changes in pattern should be made before the metal hardens in the mould.

The maximum permitted number of patients (and with it the size of the capitation fee) was decided at a time when it seemed possible that the service would start with far fewer than 20,000 practitioners. In such circumstances the Minister no doubt felt obliged to allow a doctor to have as many as 4000 patients, despite the inadequacy of personal care which this must often imply. But today, with the average number of public patients little (if at all) above 2000 per practitioner, there is not the same evident need to put the ceiling so high. The only arguments for doing so are that it allows patients a wider choice of doctor and that it allows a proportion of doctors to earn the larger income to which their popularity and industry entitle them. All agree, however, that an unaided practitioner with 4000 patients on his list can fulfil his obligations to them only if he avoids their more time-consuming demands. He must insist on their attending his surgery; he must keep his visiting-list brief; whenever possible he must send his really ill patients into hospital; and he must delegate recurrent tasks (e.g., dressings or injections of penicillin) to district nurses or hospital outpatient departments. What is left for the doctor himself is the crowded surgery, with little time to do more than treat the presenting symptoms related by each succeeding patient.

Some may say that this is an overstatement of the position; but everyone will admit that very large lists prevent us from providing a true health service and compel us instead to provide a service for disease. For the first time in our history the practitioner now has, in theory, the chance of seeing as much of his patients as he thinks necessary: he can visit them in their homes, or ask them to call again upon him, without feeling that this will add to their financial indebtedness For the first time he is free, in theory, to be a family doctor in the full sense of the words. As such his essential function is to know his patients well, to appreciate the difficulties that affect the family as a whole, and to understand the relation of these difficulties to the circumstances in which they live. This knowledge enables him to treat individual members of the family with a minimum of disturbance to the rest, to give orders that can in fact be carried out, or to help in securing additional facilities where these are needed. He is in a position to keep an eye on anyone who may need attention without yet being ill enough to seek it. And in doing all these things well he can feel that he is doing something that really matters. However efficient and accessible the consultant and hospital services may become, the practitioner will remain necessary as the first of the medical team to be consulted, and the one in closest contact with the patient and his family. All of which means that unless general practice in the new service can be kept satisfying and attractive, we shall not get a high standard of early diagnosis and treatment and we shall thereby fall short of our best effort. Unfortunately, there is ample evidence that today more than ever of the newly qualified are seeking to specialise. Interested by the glamour attaching to consultant practice, encouraged by the assured and steadily rising income promised by the specialist Spens report, and impressed especially by the oft-repeated stories of harried, overworked, underpaid, and inefficient general practitioners, they very naturally throng the examination halls in the hope of attaining specialist status

The desire to evade or escape from general practice threatens indeed to become a danger to medicine. Yet it cannot be checked, and general practice cannot be replenished and revivified with satisfactory recruits, unless we see that the pattern now being laid down is one that appeals to the new generation. Instead we find that practitioners at present are scrambling to augment their lists, and looking askance at intending new entrants to their areas, largely because of the difficulty of earning their previous income without accepting a list of patients they know to be too large. Now that the Minister is assured of enough doctors to start the service he is in a better position to consider where exactly the public advantage lies. Clearly it does not lie in the encouragement of doctors to have lists longer than they can manage; nor in the discouragement of doctors to enter general practice because it does not provide an adequate livelihood unless abused in this way. The proportion of our medical resources (both in numbers and in brains) that ought to be employed in special and in general practice is a major question of policy; and adjustment of the remuneration and amenities obtainable in these branches should be used as a means of achieving the ends desired. So far as it goes, the evidence suggests that the balance requires to be tilted towards general practice, which will otherwise degenerate instead of improving Much would be gained immediately if the Government could allow an appreciably larger capitation fee on condition that the maximum permitted number of patients is also appreciably lowered. By such a move, more young recruits might be found, and more places to employ them. The distribution of doctors might more quickly even itself, and fewer under-doctored areas remain—for areas where all the doctors have lists approaching 4000 remain under-doctored. The financial sacrifices now being asked of many who are not in a position to secure big lists would be reduced. But what matters most of all is that, as soon as may be feasible, practitioners everywhere should be in a position to do their work properly, without perpetual hurry, and that the nation should have the benefit, in fact as in theory, of a genuine family-doctor service.

International Health or World Health?

A MONTH's work by the first World Health Assembly is briefly recorded by Dr. N. M. GOODMAN on another page. Much of this work was useful and promising, but the outstanding achievement of the meeting was its proof that, even in the present state of tension, international political groupings do not retain their structure when health is under consideration. Political detachment may well be expected among clinicians or scientists, but to find it in a body of official government representatives discussing administrative problems is a hopeful sign for the future of the World Health Organisation. Anyone reading through the unidentified remarks of delegates, at least in the assembly's committees, would be hard put to discover their countries of origin, and he would have even greater difficulty in defining any general "group" policies.

This held broadly true even on the major issues of programme and budget. As we remarked at its opening,[1] the assembly had a choice between what may be called international health and world health—it could rest content with doing small things which can only be done internationally, or it could attempt to achieve a measurable improvement in the health of the world—and this choice had to be faced in the debates on the budget. The Interim Commission had proposed to the assembly a budget of 6,324,700 U.S. dollars, which already represented a compromise between the older school and the "up-and-at 'ems." The British delegation—understandably perhaps, in view of our economic situation and our conservative traditions—proposed a 4 million dollar budget. In this it received general support from the United States, for internal political reasons, in spite of the United States having been the original proponents in the Interim Commission of the "W.H.O. abolishes malaria" theory; and also from the Russians, for reasons not entirely clear, but apparently from a general dislike of "swollen bureaucracies." Only the smaller nations—and by no means those with most to gain—headed by Dr. KARL EVANG, of Norway, wished to keep to the original figure of the Interim Commission. There were many protests when the favourite subjects of the delegates or their governments had to be cut out of the programme or drastically reduced, and nearly all delegates supported, from various motives, immediate regionalisation, which still further reduced the funds that can be devoted to field work. The result was a budget of 5 million dollars—more than ample for an international health programme in the pre-war sense, yet obviously inadequate for an attack on the major diseases of the world. Indeed, on a crude population basis, the sum available for such an attack works out at less than one dollar per 1000 inhabitants of the globe. Nevertheless, this may prove to be the solution, at least for the first year of the organisation's life, since experiments on aid to governments on a limited scale may not only provide experience for the future but may achieve some useful results on catalytic lines.

There remains the problem of allocating even these comparatively small sums between the various claimants. It proved hard enough for the Interim Commission to decide between the 14 UNRRA-aided countries with a fairly well-defined programme. The assembly passed this responsibility on to the executive board, without laying down any guiding principles. How will it be possible in the future to decide between a war-damaged library in the Ukraine, three fellowships requested by the Philippines, or a B.C.G. team for, say, Liberia? This is probably the most awkward problem before the new organisation, but a solution should not be beyond the capacity of the executive board and the new director-general, Dr. BROCK CHISHOLM, to whom we extend our congratulations and good wishes in his difficult task.

A New Hope in Domestic Heating

"To have the air inside a dwelling as fresh as the air outside, it is not necessary to have it as cold."—FLORENCE NIGHTINGALE.

THE urgent need for fuel economy has given a new impetus to the campaign for smoke abatement and a new encouragement to those who demand efficient domestic heating. The Department of Scientific and Industrial Research has now established at Greenwich an active station for fuel research, which has as its principal aim the economical use of fuel in the home. Before the late war, coal in Great Britain was relatively cheap and easily obtainable. In twelve or thirteen million homes it was used for heating, washing, and cooking to the extent of 60 million tons a year—of a third of the total consumption for all purposes. Of the vast amount of heat liberated, only a fifth was usefully employed and the remaining four-fifths was wasted. Because of this our houses in general have been badly heated. In the winter it is usual to find only a small area round the fire in one room kept at a comfortable temperature, the rest of the house being bitterly cold. Even the heated room does not give a full measure of comfort, owing to the draught from the excessive quantities of cold air drawn in from outside to pass up the chimney. Furthermore, our domestic chimneys have been responsible for about half of the pollution of the atmosphere by smoke. It has been estimated that smoke emitted from coal burnt in open grates before the war carried more than a million tons of tar and soot into the air every year. During recent years industry has developed domestic heating appliances which are at least twice as efficient as the older ones and can now be obtained in increasing numbers. This means that we can have more comfortable and healthier homes and can save fuel at the same time—and a saving of 5% in the fuel used for domestic consumption means an extra $2^1/_2$–3 million tons of coal a year for the export drive. It means also a saving for the consumer's pocket, for in the past the amount spent on fuel by the average householder over a period of 40 years was often equal to the capital cost of the house.

---

[1] *Lancet*, July 3, p. 17.

Since its inception, the Fuel Research Station has been busily testing the new appliances before their release for installation in the post-war housing programme. To link up with these "laboratory" tests, the parent Department of Scientific and Industrial Research arranged a series of practical "living" experiments whereby many different types of heating appliances were installed in houses newly erected for occupation. The tenants themselves (sometimes, but not always, specially selected for the purpose), with the assistance of scientific observers, have been collecting observations on these "designs for living," on the physiological reactions of householders to the various appliances, and on the fuel consumption of each. The third stage in this enterprising research programme was the construction at the Fuel Research Station of a calorimeter building, lately declared open by Sir EDWARD APPLETON, F.R.S., secretary of the department. This building is not a research laboratory in the ordinary sense. It is really a scientific instrument for the measurement of heat. No-one has yet accounted completely for all the heat in the fuel burned in a domestic grate. The heat is very difficult to trace. It may be transmitted by radiation, by conduction, or by convection; it may reach the rooms in the house, but much undoubtedly is lost. The calorimeter building is designed to measure precisely all the useful heat and all the losses. The whole building is a piece of experimental apparatus of such a size that every experiment can be carried out with a full-size heating appliance. The broad principle underlying its use is that adopted by the physicist in his laboratory when he measures the heat from half a thimbleful of coal with a calorimeter. In the new building each room is a calorimeter, and there are four of them, each 12 feet square and 9 feet high—about the size of an ordinary living-room in a small house. The rooms are of air-tight construction with specially balanced draught arrangements to eliminate leakage and enable the amount of incoming air to be recorded. The total useful heat from the appliance can thereby be determined by direct measurement. It is also possible to measure separately radiant heat, warmed air from convection jackets, and heat to the boiler water. In this way an appliance may be tested without its performance being affected by the measuring instruments. The tests will give a complete picture of the behaviour of the appliance under different operating conditions, and with different fuels. The building also includes rooms for measuring by photo-electric methods the amount of smoke produced by each appliance under test.

"Mental anxiety may perhaps be considered the most powerful enemy to the duration of human life, and next to it defective nutriment, whether in quantity or quality, but after these no other cause at least in modern times, appears to have inflicted so great an amount of evil upon the human race as defective ventilation." The epidemics of catarrhal infections which plague us every winter are evidence that these words, written by Dr D. B. REID in 1844, are still true The Department of Scientific and Industrial Research is making a determined attempt to overcome the outstanding difficulties as they apply to the home.

Annotations

OCCLUSIVE DRESSINGS

THE search for a protective dressing that will effectively exclude liquids and micro-organisms, and will not at the same time damage the healing tissues, has recently met with some success. If maceration of the underlying tissues is to be prevented there should be evaporation through the dressing. Epithelium is particularly liable to maceration, as anyone knows who has wrapped his finger in a waterproof dressing to exclude air and water from a small cut or abrasion: the disappointing consequence—a white, sodden area extending round an imperfectly healed lesion—is one of common experience. Burnt surfaces tend to become macerated under all the usual dressings, and often this results in the destruction of the growing edges of epithelium, and of the islets of regenerating epithelium on which rapid healing depends. When the horny layer at the edges of a wound is sodden by insensible perspiration and sweat-gland secretions the danger of infection is enhanced.

A new technique in the treatment of burns has lately been described, at a meeting of the American Association for the Surgery of Trauma, by W. A. Brown, A. W. Farmer, and W. R. Franke, who have developed it at the Hospital for Sick Children, Toronto, and at the Royal Canadian Air Force institute of aviation medicine. The dressing they advocate is aluminium foil, which, they point out, is non-toxic and easily sterilised. They use this foil in sheets 0 001 in. thick, and apply it directly to the burnt surface, with a superimposed pressure dressing. The pressure is essential, since without it the wound may still become soggy. The foil is not impervious: the thin sheets have minute pores which allow of "perspiration" of the wound. With adequate pressure "weeping" of the wounds ceases very quickly. Second-degree burns examined ten days after application of the foil were found to be pink, dry, and healing by epithelisation without maceration. The dressings were odourless, and the foil had retained its sheen on both surfaces. In a series of 50 cases treated with aluminium-foil dressings there was one in which 35% of the body surface was burnt to the third degree; on removal of the foil the burns were found to be covered by a grey slough. Severe systemic reactions were encountered in only 12 of the 50 cases, and urinary output was generally unimpaired. Intramuscular penicillin was given sometimes, but not as a routine.

During the war, in the search for a method of waterproofing clothing for the tropics, it was noted that material which is highly resistant to liquid water may yet be permeable to water vapour; and last week we published an account[1] of experiments with nylon derivative in the form of a film which has these virtues together with the toughness and pliability that make it suitable for a wound dressing. Clinical trial has shown that the dressing is practical and that wounds treated with it heal well.

EXTROPHY OF THE BLADDER

CONGENITAL malformations are a rousing challenge to surgeons because of the lifelong burden they impose and because of the child's lively powers of recovery and adaptation after operation. Few congenital defects cause more grievous mental and physical suffering than extroversion, or extrophy, of the bladder, and no surgeon can remain satisfied with the results of treatment so far attained. In a paper read before the British Association of Urological Surgeons on June 26, Dr. Louis Michon, of Paris, described his attempts to restore urinary continence in these patients. The usual treatment—diversion of the urine—is not a cure and is a approaching 4000 remain under-doctored. The financial sacrifices now being asked of many who are not in a position to secure big lists would be reduced. But what matters most of all is that, as soon as may be feasible, practitioners everywhere should be in a position to do their work properly, without perpetual hurry, and that the nation should have the benefit, in fact as in theory, of a genuine family-doctor service.

species of amœbæ living in the gut of man and of animals is extremely difficult, and it is often uncertain and insecure. Perhaps a given specimen really is *E. histolytica*; perhaps it just looks like it. For another thing, man himself is an important reservoir for the organism, and 10–20% of the ordinary adult population of England carry amœbæ which are *E. histolytica* or which cannot be distinguished from it. Yet, owing to some mysterious factor which is still unknown, very few of these carriers show evidence of dysentery, even on sigmoidoscopic examination. Rats cause great economic loss by their destruction of foodstuffs and other goods. They are potential carriers of several dangerous infections. If they also carry dysentery this does little to add to the sum of their iniquities. They ought to be destroyed, and to a large extent in this country the rat population has been destroyed, or reduced to small proportions. In the light of Neal's work, places which contain many persons infected with amœbic dysentery—e.g., Ministry of Pensions hospitals—should pay special attention to the destruction or exclusion of rats.

BETTER USE OF BEDS

THE fear that an elderly patient may block for a long time a bed which could be used over the same period for a considerable number of acute cases has sometimes led hospitals to refuse admittance to acutely ill old people.[1] This danger has been in the minds of the British Medical Association committee on the care and treatment of the elderly and infirm; and in the first supplement[2] to their 1947 report they urge the importance of getting the right patient into the right bed. The report recommended that an integrated geriatric service should be set up, based on departments in selected general hospitals. The committee have again considered the plight of the acute hospitals in meeting the demand for beds staffed with skilled nurses. If the measures recommended in the report were adopted, they believe that the bed shortage would be eased in two ways. First, sick old people would be investigated fully in the geriatric department and would therefore spare beds in the acute wards. Secondly, if enough long-stay annexes are provided for the really incurable cases, and if homes and hostels are provided for old people no longer fit to look after themselves but not requiring continuous skilled nursing, many old people now occupying beds in acute hospitals could be transferred to the appropriate surroundings. A telling example illustrates present difficulties: 8 old men not in need of active treatment have continuously occupied beds for two years which could otherwise have been used for some 360 acute surgical cases.

The committee now make some further suggestions. Short-stay hostels, they think, might be set up close to hospitals, where old people—and indeed patients of all ages—might stay for a few days while diagnostic tests were done. These hostels could be staffed by orderlies and attendants working under the minimum of skilled nursing supervision. In addition like Dr. Thomson and Dr. Curran (p. 241), they suggest convalescent hospitals—as distinct from convalescent or holiday homes—should be provided where patients might be taken by ambulance when not acutely ill but nevertheless in need of some bed-rest and nursing care. Patients with uncomplicated postoperative conditions, for example, could complete their recoveries in such hospitals, which could be staffed with a much lower proportion of trained nurses than acute hospitals. When it comes to deciding who should doctor these patients, the committee cautiously propose a compromise: the specialist staff of the hospital should "retain their responsibility" in such cases until the conclusion of the treatment, but they might with advantage, they think, have the coöperation of a local general practitioner, who would be appointed as medical officer to the convalescent hospital. This would take a little working out, for an unforeseen complication might occasionally arise while the M.O. was out on his rounds. Better facilities for outpatient care of old people would also, the committee believe, relieve pressure on beds. In a general hospital, the geriatric outpatient clinic, under a physician, would have the specialist resources of the other departments—and especially the physiotherapy department—to hand, and could provide the services of a dentist and a chiropodist; while the hospital dietitian and the almoner could both give the old people appropriate help. Patients should be brought to the outpatient clinic by transport arranged by the hospital; and adapted shooting-brakes, running a shuttle service, do very well for this purpose.

One regional hospital board has already set up an advisory committee on geriatrics, and the committee commends the idea to others. They also repeat their proposal that standing liaison committees should be established to coördinate the work of the different bodies concerned with the care of old people—that of the regional boards and the local authorities, for example. Finally they remind local authorities that they can do much to prevent old people reaching hospital by providing adequate home help and nursing services.

PHAGE-TYPING

IN bacteriology, species and types of organisms can often be identified by specific antibody reactions, and in this way we have learnt much about the epidemiology of some of the infectious diseases. Sometimes the serological sieve is useless because all strains fall into a few main groups, and for organisms like the typhoid bacillus bacteriophage-typing has been used instead. This method depends on the discovery by Craigie and his co-workers of an anti-Vi bacteriophage which developed specificity for the particular strain of *S. typhi* on which it was propagated. Using a series of phages adapted in this way it is possible to type a large proportion of strains freshly isolated from infected people.

Success in this field naturally led workers to try phage-typing with other organisms, such as *Staphylococcus aureus*, where ordinary serological methods gave indifferent results. Fisk[1] described a cross-culture technique of isolating staphylococcal phages, and the method was developed and given practical application by Wilson and Atkinson[2] in this country. Staphylococcal phages are not prepared in the same way as those for *S. typhi*, but a considerable degree of strain specificity has been obtained. At least a third of the population has resident staphylococci in the vestibule of the nose or on the skin, and this makes it peculiarly difficult to trace the source of staphylococcal infection. With the 22 bacteriophage filtrates of Wilson and Atkinson, routes of infection can be traced in outbreaks of food-poisoning and in some of the hospital infections caused by staphylococci. A good deal of information has already been gathered about breast abscess, pemphigus neonatorum, and sticky-eye, which are still much too common in maternity practice. Accurate identification of strains has also helped to show how these infections can be prevented, but we still do not know whether boils or other skin infections are caused by the patient's resident strain nor how staphylococci spread within families or larger groups. Methods of identifying enterotoxic strains are unsatisfactory and phage-typing might well help us here. It has been suggested that penicillin-resistant strains of staphylococci are becoming more common, but again we do not know if this is a general phenomenon or if it occurs mainly among inbred hospital strains.

confession of failure, for the lack of a functioning bladder and urethra has a serious emotional effect on adolescents and particularly on boys. For many years, therefore, Michon has been trying reconstructive operations, and in spite of disappointments his results have been encouraging.

The first problem is to refashion the bladder, and this can usually be done successfully; but the patient is then virtually no better off, since he is still incontinent, and the far more difficult task of contriving a new sphincter has to be faced. The ingenious method of transplanting a loop of the gracilis muscle may be successful, but one of Michon's cases showed clearly that the new sphincter did not depend on muscular action but on the ring of scar tissue around the urethra. The same effect can be produced more simply by the ribbon catgut method, but these cases suffer from the disadvantage of having no bulbocavernosus to pad the ring. An important point is to suture very carefully the muscle forming the neck of the bladder. By these methods gratifying results may be obtained, with normal micturition and clear urine. Michon described one such case, first operated on 20 years ago when the patient was a boy of five, who won distinction on active service in the late war. But even in hopeful cases reconstructive surgery may fail, and often it should not be attempted, particularly in the very young and in those with great hypoplasia of the bladder.

Diversion of the urine, though not ideal, is a sound alternative to reconstructive operations and has some advantages over them. With improved technique and modern chemotherapy the operative mortality is much reduced and the risk of subsequent infective complications lessened. It can be done at a much earlier age (soon after the end of the first year) and thus saves the mothers much trouble and distress. It can be used irrespective of the degree of hypoplasia of the bladder and is thus applicable to a much higher proportion of cases than reconstruction is. Finally, it allows the bladder to be excised and thus removes a possible source of malignant disease; as Graham pointed out in the discussion of Michon's paper, the exposed bladder mucosa soon undergoes metaplasia with the formation of cystitis glandularis, and there is a high incidence of adenocarcinoma later. Although covering the exposed mucosa by an early reconstructive operation may reverse these changes this cannot be taken for granted. None of these considerations must be neglected in the search for the ideal treatment of extrophy of the bladder.

EMPLOYMENT OF WOMEN

> "The country is faced with the task of maintaining, and if possible increasing, the female labour-force at a time when the number of women of working age is declining. The difficulty is enhanced by the even greater decline in the number of women under forty-five years of age, from whom the bulk of the female labour force is drawn."

REVIEWING this dilemma P.E.P. suggest[1] that the Ministry of Labour should forecast the probable trend in the number of women available for work in the various regions and industries during the coming fifteen years or so, and should make the findings widely known. Systematic studies are also needed to decide what jobs are done better by women than by men, and whether they are now done by women. It is clear, they say, that any substantial increase in the number of women in employment must come from married women, and that if there is not to be a considerable fall in the women's labour force, there must be a big rise in the number of middle-aged and elderly women employed. The important thing is to relax the present pressure on mothers with young children to take jobs.

P.E.P. believe that by far the most hopeful meth of gaining these ends is to extend the opportuniti for part-time work. This offers housewives some mon and wider interests, without the strain which a full-tim job imposes on a woman who must also run a hous It means there must be more careful planning and organising by employers, but there is evidence tha part-time workers give good service, and that their output is often better than that of full-time workers; nor do they compare badly in absenteeism and labou turnover. "The Ministry of Labour and employers of all kinds, including schools and hospitals," P.E.P. insist, "as well as business firms, must realise that unle they make a real effort to extend part-time work, industrial production and the social services will suffer." This has a special significance for hospitals, wher part-time nursing and the employment of married wome could and should be greatly developed.

RATS AND AMŒBÆ

THE association of rats with human disease is wel known, the most notorious example being plague, when first the rats die, and then the men die as the causativ organism *Pasturella pestis* is conveyed by fleas from th stricken rodents to the humans. Typhus is anothe familiar example. During the campaign in Burma th much-dreaded scrub typhus was due to *Rickettsi orientalis*, which is naturally a pathogen of rats, spreadin to man only as a secondary event. Rats form the reservoir for *Leptospira icterohæmorrhagiæ* and other organisms. Recently attention has been drawn to the possibility that rats may also spread amœbic dysentery. During the last thirty years occasional reports from many parts of the world have described rats containing amœbæ which resemble *Entamœba histolytica*. The first report[1] referred to wild rats at Charleston, U.S.A., in 1915. Afterwards Brug[2] described *E. histolytica* in tw rats in the Dutch East Indies. Later workers[3,4] hav recorded the presence in rats of amœbæ indistinguishabl from *E. histolytica* in Moscow and in Iraq. The lates report comes from London.

During a survey of the incidence of amœbæ parasiti in rats, Neal[5] found that 7 out of 11 rats collected at on particular place contained amœbæ with the characte istics of *E. histolytica*. Although the infection differe from human dysentery in that most of the forms were i the trophozoite phase and cysts were extremely scanty the morphological features were those of the huma pathogen. The organism could be cultivated in vitro b standard methods. When it was inoculated into the cæcu of young rats, typical ulcers were produced in many o the animals. These infections could be prevented b emetine. The house where the infected rats were caugh was inhabited by Cypriots, five of whom had arrived fro Cyprus during the previous six months. Seven of thes people were examined for protozoa and two were foun to be passing abundant cysts of *E. histolytica* in thei fæces. An investigation of the circumstances in whic the infected rats were discovered showed that there wa no trap between the sewers and the drainage system o the house in question. Owing to this defect the rat could gain access to the house from the sewerage. Twelv wild rats from other sources were all free from th infection.

The evidence thus suggests that rats can act as reservoir of infection for human amœbic dysentery, bu caution should be observed in concluding that this ofte happens or that rats are important in spreading thi disease. For one thing the identification of some of th

FIRST WORLD HEALTH ASSEMBLY

NEVILLE M. GOODMAN
M.D. Camb., D.P.H.
DIRECTOR, FIELD SERVICES, WORLD HEALTH ORGANISATION

Now that the World Health Assembly has concluded its first annual session on July 24 after five weeks of labour, a factual summary of its work can be made.

DECISIONS OF THE ASSEMBLY

Officers and Committees.—Dr. A. Stampar (Yugoslavia), chairman of the Interim Commission, was unanimously elected president of the assembly. Dr. G. H. de Paula Souza (Brazil), Sir Aly Tewfik Shousha, Pasha (Egypt), and Rajkumari Amrit Kaur (India) were elected vice-presidents. In addition to the general or steering and credentials committees the assembly established committees on programme (Dr. K. Evang, Norway, chairman); relations (Dr. Melville Mackenzie, U.K.); headquarters and regionalisation (Dr. J. Zozaya, Mexico); administration and finance (Dr. M. Kacprzak, Poland); and legal questions (Dr. C. Van den Berg, Netherlands).

Work of the Interim Commission.—The first days were occupied with a general discussion of the report of the Interim Commission on its activities since its establishment in July, 1946. In spite of some criticisms the report was unanimously adopted and the commission congratulated on its work. It was decided that the Interim Commission should formally be dissolved on Sept. 1.

Admission of New Members.—Nine countries were admitted as new members during the assembly, bringing the total membership to 54, with several others expected in the near future. A total of 66 nations were represented at the assembly either by delegates or observers, two members—Afghanistan and Transjordan—not sending a delegation. In spite of certain reservations made by Congress to the U.S.A. ratification, notably in a claim to withdraw at one year's notice, the assembly unanimously decided to disregard the reservations and admit the United States to full membership.

Election of the Executive Board and the Director-General.—After several adjournments the assembly accepted by a substantial majority the list of 18 countries designating a member of the executive board.[1] Lots were then drawn for the two groups of six countries retiring in one and two years' time respectively, but eligible for re-election: both the U.K. and the U.S.A. fell into the first group. The executive board unanimously nominated Dr. Brock Chisholm, executive secretary of the Interim Commission, for election as director-general of the World Health Organisation, and this was confirmed by the assembly.

Headquarters.—The Economic and Social Council of the United Nations, now in session at Geneva, approved the assembly's choice of Geneva as its permanent headquarters.

WORK OF COMMITTEES

The *Programme Committee* spent a long time working through the list of subjects which might be taken up by W.H.O. and then deciding on priorities. To the *four* major activities proposed by the Interim Commission—malaria, tuberculosis, venereal diseases, and maternal and child health—were added environmental hygiene and nutrition. In the second group were placed public-health administration, hospitals, medical care and rehabilitation, medical social work, nursing, health education, industrial hygiene, and the hygiene of seafarers—the last two jointly with the International Labour Office. After this, in order, came parasitic diseases, virus diseases, mental health, and alcoholism, and finally a mixed group including cancer, leprosy, and rheumatoid diseases. The methods by which the programmes in these subjects will be implemented range from demonstration teams and other considerable field services, through expert committees, to the part time of a single specialist; but budgetary considerations may prevent anything at all being done at present in fields with a low priority. Expert committees on eight subjects were later authorised by the executive board to be set up at once, initially as nuclear groups.

The *Committee on Relations* had the difficult task of establishing formal relations with a number of bodies with whom the Interim Commission necessarily could only make working arrangements. These include the United Nations itself, the Food and Agriculture Organisation, UNESCO, I.L.O., and the International Children's Emergency Fund. Various joint committees, both organisational and expert, were authorised. Thus all medical programmes of ICEF will in future pass through a joint committee of W.H.O. and ICEF: since these projects amount to a larger budget than that of W.H.O., the importance of this committee is obvious. Coöperation with UNESCO will include, inter alia, a share in the bureau for coördination of scientific congresses. A general resolution insisted upon full preliminary consultations and joint surveys before W.H.O. undertook joint projects in the future. The integration of the Pan-American Sanitary Bureau with W.H.O. was taken a step further with authorisation to the executive board to conclude a definite agreement with a working arrangement in the meanwhile. Finally, principles for coöperation with non-governmental organisations were adopted, and criteria for their recognition: the executive board later accepted seven well-known organisations for formal recognition.

As previously noted,[1] the *Committee on Regionalisation* divided the world into six areas. Each area will form a regional committee of W.H.O. with a regional office, when a majority of the members in the area so decide. For the Americas, the P.A.S.B. when integrated will serve as the regional office. The bureau at Alexandria will act for the Eastern Mediterranean area, and Europe will have a special temporary office for "the liquidation of war damage" in the field of health. The remaining areas are the Western Pacific, South-East Asia, and Africa.

The *Administration and Finance Committee* decided at an early session to aim at a 5 million dollar budget for 1949, and then had the difficult and distasteful task of fitting the programme into a budget, planned by the Interim Commission for $6^1/_2$ million, which even then did not include funds for regional offices. Since the statutory and administrative items could not be substantially cut, the services to governments suffered most heavily. The adjustment was eventually made largely by provision for lapses—i.e., by assuming that a high proportion of posts would not be filled until late in 1949. In addition this committee dealt with a mass of matters such as the scale of contributions—the United Nations' scale was adopted, the United States dissenting—the budget for the remainder of 1948, staff regulations, allowances for members of the executive board, and appointment of external auditors. Much of the detailed work was necessarily handed on to the executive board for action.

The *Legal Committee* held a number of meetings on important questions such as the rights of associate members and the rules of procedure of the assembly and of expert committees.

Finally it was agreed that next year's assembly should meet in Europe, the executive board to decide on the place of meeting in the light of invitations received.

[1] See *Lancet*, July 24, p. 153.

These are a few of the problems which phage-typing can help to solve.

Staphylococcus aureus is one of the most ubiquitous of potential pathogens, and coagulase-positive strains can readily be isolated from many domestic animals. There is little information about the relation of animal strains to human disease. Macdonald[3] has shown that bovine mastitis in Norfolk is caused by a single phage-type of staphylococcus, in contrast to the multiplicity of types found in human disease. This has been confirmed for other areas by Smith,[4] and it may prove of interest in the study of the ecology and perhaps also in the evolutionary history of the staphylococci. Smith has also shown that the single bovine phage-type can be subdivided by using additional phages. This was made possible by the acquired phage-resistance of some of the strains. He points out that apparent differences in phage-type may sometimes be caused by such acquired phage-resistance. The different phage-types are quite stable in the laboratory, but Smith reminds us that staphylococci, like most living things, may also become infected with other phages, or with viruses. Phage-typing is essentially a means of experimental infection, and whether the test animal be guineapig or staphylococcus its past experience may influence its present behaviour.

SIXTY YEARS OF MEDICAL DEFENCE

IN the early 1880's two Dulwich doctors, though successful in defending themselves against a charge of manslaughter and a claim for damages, found themselves out of pocket by over £1000. Soon afterwards a Chesterfield practitioner, accused of an attempted assault upon a woman patient, actually served eight months in prison before vigorous professional protests secured him a free pardon. Sir William Jenner initiated funds in the one case to make good the loss and in the other to re-establish the victim of a tragic ordeal. These experiences showed the need of some organisation for mutual help, and in 1885 the Medical Defence Union was born. All will join in congratulating it upon the successful record of *Sixty Years of Medical Defence* written by its present secretary, Dr. Robert Forbes.

The M.D.U. began modestly with 400 members and an annual subscription of 10*s*. Its present membership is over 31,000 and its reserve funds exceed £175,000. Practitioners, we learn, have besought its aid in small things as well as great—the too insistent crowing of a neighbour's cock or the tracing of a drunken locum tenens who had run off with the cash in hand and the keys of the surgery. One member complained that he was being hypnotised; another wanted help in controlling his wife. The major activities within its proper province ranged from prosecutions for the false assumption of medical titles (as when a commercial "Botanic Company" was found to be selling the titles of M.D., B.C.) to detective work in tracking down cases of impersonation. New difficulties merely stimulated progress. Just as the union was arranging to increase its members' indemnity to £3000, there came the staggering award of £25,000 against two doctors, in Harnett *v.* Bond and Adam, for wrongful detention under the Lunacy Acts. The union boldly decided to give thenceforward unlimited financial protection against damages and costs incurred in defensive or offensive litigation, provided that the member accepted the council's decision and advice. How sound that advice could be we can judge from the fact that, out of the 448 libel and slander cases undertaken in the years from 1896 to 1905, only 3 were lost. Unquestionably the continuity of expert legal guidance, happily associated with two generations of the firm of Hempson, played a great part in these successes. In 1934 the enactment of the Law Reform (Miscellaneous Provis Act brought another enlargement of scope. The made it possible to maintain an action for perso negligence against the estate of a deceased practition In one well-known case, where the defendant doc died in the course of the hearing and his widow remain liable, a verdict of £5000 was awarded for a failure diagnose tuberculosis. Hitherto the membership of t M.D.U. had been personal and benefits had ceased with death; new provision was needed for this new liability. It is not perhaps surprising that the membership, which had nearly doubled itself between 1919 and 193 continued to increase. The Harnett case had brought a record new entry. A little earlier, in Claydon *v.* Wood-Hill, £750 damages had been given against a defendant practitioner for negligent treatment of a fractured femur, and his financial loss amounted in all to some £225 The profession was shocked to learn that he was not a member of any defence society and naturally the need of universal protection was canvassed afresh. The council of the British Medical Association passed a resolution and its organisation committee invited representatives of the two defence societies to a conference, but, after negotiations which Dr. Forbes describes, it was appreciated that individual medical defence was not likely to be better or more cheaply conducted than by the existing bodies.

Amalgamation of the two has, of course, been suggested. Soon after its formation in 1893, the London and Counties Medical Protection Society (now the Medical Protection Society) approached its older rival with a proposal. A few years later, in 1899, it tried again. Our columns of that date contained a recommendation for a single strong organisation; we had hinted a criticism of the apparent reluctance of the M.D.U. as illogical and non-coöperative. Ideas of centralised medical defence, periodically ventilated at meetings of the B.M.A., presupposed the pooling of the experience and resources of the existing bodies. The two societies, working on parallel lines not only for individual protection but also for professional standards and harmonising their activities and their objects through their standing joint committee established in 1894, continue their separate wo Meanwhile the costs and risks of litigation are risin The other day a judge candidly increased an award damages on the ground of the diminished purchasing value of money.

Close on fifty years ago THE LANCET vigorously advocated membership of a defence society, and that advice is just as necessary today. Both the Medical Defence Union and the Medical Protection Society are doing invaluable work for the profession.

TUBERCULOSIS IN SCOTLAND

NEWS of an increasing incidence of tuberculosis in Scotland, on which we commented in a leading article on July 24, has been followed by the appointment of a committee to examine the position. Established by the Scottish Health Services Council at the instigation of the Secretary of the State, the committee includes three members of the council: Captain J. P. Younger (chairman), Dr. Matthew Fyfe, and Dr. J. R. Langmuir. The other members are: Prof. Charles Cameron, Prof. F. A. E. Crew, F.R.S., Dr. H. C. Elder, Dr. Stuart Laidlaw, and Dr. A. B. Maclean.

DR. T. CRAWFORD has been appointed to the university chair of pathology at St. George's Hospital medical school. Since 1946 he has been director of pathological services at the school.

DR. D. V. DAVIES, lecturer in anatomy in the University of Cambridge and fellow of St. John's College, has been appointed to the chair of anatomy at St. Thomas's Hospital medical school.

TABLE II—ANALYSIS OF MOVEMENT OF 2937 STATE-REGISTERED NURSES AFTER THREE-YEAR AND FOUR-YEAR TRAINING

	Three-year	Four-year
Total trained	1533	1404
	%	%
Gave up nursing	14·3	16·9
Went abroad	3·6	3·1
Entered the Services	0·5	1·3
Entered non-hospital employment ..	9·0	7·2
Became pupil midwives	29·4	44·5
Took other training courses	5·0	1·8
Entered first employment in hospital ..	38·2	25·2
	100·0	100·0

hospitals are in the latter group, the total number of nurses training in each group are not very different: the three-year training gave an output of 1533, compared with an output of 1404 for the four-year training. Table II shows the results.

The larger number entering hospital employment after the three-year training is probably due to the fact that nurses who have had the shorter training are more likely to feel the need of another year's experience as staff nurse. Other variations may be due to economic factors. Most of the teaching hospitals are in the four-year group, and possibly girls training in them are in a position to regard home claims and the like as reasons for giving up salaried work more readily than girls training in other hospitals.

VOLUNTARY AND LOCAL AUTHORITY HOSPITAL TRAINING

10. An analysis has also been made of the results in voluntary hospitals as compared with those in the L.C.C. hospitals. The 44 voluntary hospitals had an output of 2019 nurses, or an average of 46 per hospital, while the 24 L.C.C. hospitals had an output of 918 nurses, or an average of 38 per hospital. In the voluntary hospitals the output varied between 5 and 215 nurses per hospital (7 having an output of over 100), while in the L.C.C. hospitals the variations was between 16 and 89 per hospital. In table III the movements of nurses from the two types of hospital are compared.

The substantially higher proportion from L.C.C. hospitals going on to "other training courses" probably reflects mainly those who went on to fever, tuberculosis, or children's training within the Council's service, more or less as an equivalent to remaining as staff nurses in their training hospitals. If this is the case, it suggests the advisability of grouping sanatoria and other "special" blocks with general hospitals in management committee groups, since the nurses would probably transfer more readily to them for further training than they would migrate to another group. Since the L.C.C. hospitals give a three-year training, the 13·4% who gave up nursing should be set against the 14·3% who gave up after three-year training, rather than the 16·5% who gave up from all the voluntary hospitals, since most of the latter have had a four-year training.

TABLE III—ANALYSIS OF MOVEMENT OF 2937 NURSES AFTER TRAINING IN VOLUNTARY AND L.C.C. HOSPITALS

	Voluntary	L.C.C.
Total trained	2019	913
	%	%
Gave up nursing	16·5	13·4
Went abroad	2·7	4·7
Entered the Services	1·1	0·5
Entered non-hospital employment (private nursing, industry, &c.)	7·3	9·9
Became pupil midwives	38·8	32·4
Took other training courses	2·2	6·3
Entered first employment in hospital ..	31·6	32·8
	100·0	100·0

REASONS FOR GIVING UP NURSING AFTER TRAINING

11. Finally, an analysis has been made of the reasons stated for the loss to nursing of 456 newly trained nurses. Results are given in table IV.

MAIN CONCLUSIONS

The three most salient facts which emerge from the survey are:

(A). Only 32% of all those whom the London hospitals train in general nursing continue directly to practise it in hospital. This takes into account only those who complete their training and ignores all who "waste" during training.

(B). 36·3% go on from general nursing to midwifery training, but of these possibly half return to general hospital work immediately after the course.

(C). 15·5% give up the practice of nursing immediately after training.

TABLE IV—REASONS FOR GIVING UP NURSING ON COMPLETING TRAINING (456 NURSES OUT OF 2937 TRAINED)

—	—	% age of no. trained	% age of no. giving up
Gave up for:			
Marriage	295	10·04	64·7

Reasons not stated	78	2·66	17·1
	456	15·50	100·0

(A.) The fact that the hospitals have to train approximately three times as many nurses as they are able to retain on their permanent staff (let alone the number they would like to retain) surely deserves as much attention as the wastage during training. These figures leave out of account the wastage during training. If we accept the Working Party's estimate of a wastage-rate of 36%, or a survival-rate of 64%, this means that only 20% (32% of 64%) of those who enter for training remain in hospital posts immediately after completing training—i.e., the hospitals must admit approximately five times as many student nurses as they can hope to retain on their trained staff.

The question arises how an adequate ratio of trained nurses to student nurses—which is a prerequisite for "student status"—is to be achieved while the hospitals have to train for ever wider fields of work outside their own sphere. Although the proportion going on to non-hospital work may seem insignificant (table I) it must be remembered that health visiting, district nursing, and most overseas posts all require the first part of the midwifery training and therefore draw from the group who have gone on to that course. One answer would

LOSS OF TRAINED NURSING STAFF FROM HOSPITALS

REPORT ON A SURVEY MADE BY THE NURSING RECRUITMENT SERVICE, KING EDWARD'S HOSPITAL FUND FOR LONDON

1. THE King's Fund, in common with other interested bodies, was invited to submit to the Minister of Health comments on the report of the Working Party on the recruitment and training of nurses. In the Fund's comments reference was made to the serious and increasing loss of trained staff from hospitals shortly after completing training. Figures were quoted in support of this statement, but it was admitted that insufficient information had been collected to give a representative sample.

2. In order to collect such information, a questionary was sent out in February, 1948, to all voluntary hospitals and London County Council hospitals in the Fund's area which were complete training schools for nurses. In tribute to the ready cooperation of the hospitals it should be noted that all the 24 L.C.C. hospitals which were complete training schools returned the questionary, and 46 *out of the* 48 *voluntary hospitals*. Two returned questionaries have been discarded as incomplete. The report which follows is thus based on information supplied by 68 hospitals (44 voluntary and 24 L.C.C.), and relates to the movement of nurses immediately after completing training, and to the period between June, 1946, when "controls" were removed from nurses, and February, 1948.

3. It is at once evident that the figures would vary considerably if a count were taken a year later, or even less. Some who gave up nursing for home reasons might have been able to return, for instance; many more who stayed on in hospital might have left after a few months, while some who left for midwifery training would have returned or taken a post in another hospital. It seemed, however, that it would be asking too much of the hospitals to trace the movements of their graduates over a year or longer, and even then no finality would be reached since the movement may be two-way at any time, and the results could not be shown simply as a descending graph.

NURSES LEAVING THE PROFESSION

4. The returns relate to 2937 nurses who completed training during the period under survey. The actual total completing training was slightly larger, but those whose movements after training were not known to the hospital have been *omitted—probably most of them left* the hospital service. Of the 2937, 456 gave up nursing altogether—a wastage-rate of 15·5%. An analysis of the reasons stated for giving up nursing has been made and is shown later. Some who had been entered by the matrons on the questionary as "*gave up on marriage* but took up part-time work in hospital" have not been counted as giving up, but have been added to the total of those who entered first employment in hospital. This wastage-rate of 15·5% at the end of training needs to be set against the wastage-rate of 5·3% during the third year of training which may be calculated from the Working Party's tables.[1] It seems clear that many defer their departure from the profession in order to obtain their full qualification, and that if a two-year training were given, this high wastage-rate after qualifying would be put back to the end of the second year. It is impossible to believe that a two-year training would attract sufficient additional recruits to compensate for the loss of the service of so many third-year nurses.

NURSES LEAVING THEIR HOSPITALS

5. Of the 2481 not giving up nursing, 1076 (36·6% of the total trained) went on to midwifery training, and 102 (3·5%) to other trainings. It is mainly the la exodus to midwifery training which foils all attemp to decide what *proportion of those* the hospitals t they can count on for their own staff. According to figures supplied by the Central Midwives' Board, 56% of those who take part I of the midwifery traini go on to part II, which qualifies them to practise midwives; but in fact only 40% of these remain in midwifery. Thus of the 1002 taking part I in midwifery, approximately 241 would enter the midwifery service, leaving 761 to take up district nursing, health-visiting, school nursing, industrial nursing, to go abroad, and so on, as well as to remain in hospital service. In view of the *fact that* part I midwifery training is needed for nearly all the above-mentioned non-hospital branches, it *may be* assumed *that* a large number of those taking part I are going on to them. It is very unlikely, therefore, that of the 761 more than 500 return to hospital work, and the *numbers may be much* less. *It must be* pointed out that whereas the other figures given in this report are actual data collected from the hospita the figures in the foregoing sentence and in the last sentence of para. 7 are estimates only, based on the data collected.

6. Of the remaining 1303 who continued to nurse but did not take further training, 98 went abroad, 26 joined the nursing services of the Crown, and 239 took up nursing away from hospitals. The questionary not ask that the forms of non-hospital nursing should be specified, *but it is surprising to find that* a number of matrons have made special mention of private nursing under this heading. The remaining 940, or 32%, took up first employment in their own or some other hospital.

TABLE I—ANALYSIS OF MOVEMENT OF 2937 STATE-REGISTERED NURSES ON COMPLETING GENERAL TRAINING

	%
Gave up nursing	15·5
Went abroad..	3·4
Entered the Services	0·9
Entered non-hospital employment (private nursing, industry, &c.)	8·1
Became pupil midwives	36·6
Took other training courses..	3·5
Entered first employment in hospital (other than training)	32·0*
	100

* This includes a few part-time nurses.

7. *It will* be remembered *that* the Working Party states that since approximately 9300 nurses qualify for the various State registers and the Royal Medico-psychological Association certificate annually in Great Britain, it could be assumed that nearly 10,000 nurses entered first employment in all hospitals each year. If we added to our 940 remaining in hospital *the maximum* of 500 ex-pupil-midwives mentioned in para. 5, we would have a total of 49% returning to the hospitals or 4557 out of the 9300 qualifying, rather than "nearly 10,000."

8. Percentage findings based on the answers to the questionary are shown in table I.

THREE-YEAR AND FOUR-YEAR TRAINING

9. The returns have also been analysed to see what difference, if any, there is in the results after a three-year and after a four-year training. Forty-seven of the hospitals give a three-year training, and twenty-one a four-year training. As, however, most of the largest

---

[1] Report of the Working Party, p. 90, table D, and p. 29, para. 82.

These show the life lived by two little boys whose father is warden on a Rhodesian game reserve. The animal pictures are exceptionally good. and the films give a fair idea of life in this out-of-the-way place, the fruits the children eat. the games they play, and the dangers they run. The principle of letting audiences see how the other child lives is borne out by *Our Club Magazine*, a series showing cinema club members at play in various parts of Britain.

The clubs form local committees made up of representatives of the local education authority, and of organisations interested in the welfare of children. as well as a youth-club leader. and elected members of children forming the club. These children, and the club stewards. are able to tell the committee. and the managers of the cinemas, how various types of film have been received and criticised. The usual price of admission is 6*d*.—a non-profit-making charge. Any surplus goes towards encouraging club activities outside the cinema, and any loss is made good by the Rank organisation. Outside activities evidently form an important part of the club's work in some localities, outings and competitions being arranged: a fishing competition, a visit to a lifeboat, a steamer trip up the Tyne were among the occasions reported in the club magazine.

It is clear that these clubs are making a useful contribution to youth movements and it is therefore all the more important that a large and reliable pool of films should be made available. that the cutting of unsuitable material is not overlooked. and that all cinemas giving children's matinees should conform to the standards maintained in the best type of club.

The question of serials also needs considering. The children like these exciting episodes greatly, but it is hard to ensure that the excitement is of a kind to be borne easily by the nervous child, and free of other undesirable qualities; and there are not enough of the right kind in hand. Nowadays the serial goes in the middle of the programme, not at the end; so that at least the children leave the theatre on a satisfying final note. and not in that suspended day-dream which (in the time of the *Perils of Pauline*) often took your correspondent almost under a bus.

CANADIAN MEDICAL ASSOCIATION

THE 79th annual meeting of the Canadian Medical Association, held in Toronto from June 21 to 25, was attended by 2024 members—a record number, amounting to one in six of doctors in Canada. The guests included Sir William Fletcher Shaw, who spoke on the Scientific Outlook and also gave an address to the graduating class at Toronto University; Prof. Brian Maegraith, dean of the Liverpool School of Tropical Medicine, whose subject was the Physiological Approach to Medical Problems; Dr. Frank Walsh, of Baltimore, who addressed a general session on Myasthenia Gravis; Dr. C. O. Sappington, of Chicago, an outstanding figure in the comparatively new field of industrial medicine; and Dr. P. S. Hench, from the Mayo Clinic, whose topic was arthritis.

A number of affiliated societies met during the convention and the round-table discussions in several departments occupied the mornings. The Lister lecture was attended by some 400 people, who heard Dr. W. E. Gallie, emeritus professor of surgery in the University of Toronto, set forth the ideals for the training of surgeons, in an address entitled the Practice of Surgery in Canada.

In a colourful ceremony Dr. F. G. McGuinness, of Winnipeg, president of the association, installed Dr. William Magner, of Toronto, as his successor. Dr. Magner, a graduate of Cork, came to Toronto as a pathologist in 1922 and was appointed an assistant professor in the university department of pathology.

The Canadian Physicians' Fine Art and Camera Salon proved a great attraction. As a hobby, art seems to appeal to an increasing number of Canadian physicians.

The planning of the convention was perfect with one exception—only 2200 programmes had been printed, and the supply ran out.

NATIONAL HEALTH SERVICE AND THE PUBLIC

B.M.A. STATEMENT

THE following statement has been issued by the British Medical Association in connexion with recent allegations in the House of Commons.[1]

When Miss Alice Bacon, M.P., made her statement in the House of Commons accusing some doctors of improper practices, the association at once informed her that if she would provide details it would make prompt inquiries. Miss Bacon, however, declined the invitation, saying that her proper course as an M.P. was to lay the matter before the Minister. None the less, the association, as representing nine out of ten of all doctors, is obviously concerned to see that a situation which is new to more than half the population in the country, and to many doctors, is clarified. Accordingly an examination has been made of the reports reaching the association and of the misconceptions which are chiefly prevalent.

The National Health Service has on the whole started smoothly in most districts of the country. None the less difficulties are being met with—as is natural and indeed inevitable with such a vast and far-reaching piece of social legislation. These difficulties should neither be exaggerated nor glossed over. It would be unfair to put the blame on doctors for misunderstandings which are not of their making. It would be still more unfair to charge the entire medical profession with incorrect behaviour which actually involves a very small minority indeed.

Some of the alleged "abuses" charged against individual doctors are clearly not abuses at all in any ethical, still less in any legal sense. Others spring from a simple misunderstanding either by the doctor or by the public. The following points, however, deserve emphasis:

1. The basis of family medical practice is free choice. The country wants free choice, and free choice works both ways. No doctor should be forced to become the doctor of any particular patient, just as no person should be forced to become the patient of any particular doctor. The family doctor has the right to refuse to accept any individual as a patient. Nor need he give any reasons for his refusal, just as no patient need give reasons for choosing, or leaving, a particular doctor.
2. The National Health Service is open to everyone in the country irrespective of income. The association is confident that the profession in general would strongly deprecate the refusal by any doctor to accept an individual as a National Health Service patient on financial grounds. Obviously the decision to be a public or a private patient must be a matter for the individual patient. Incidentally there are two misapprehensions that are fairly general. First, that everyone in the country is required to be on a doctor's list of public patients; secondly, that since July 5 private practice is no longer permitted. Both beliefs are, of course, incorrect. Registration with a doctor is a voluntary act. Private practice by doctors who have joined the National Health Service is fully protected by the law.
3. Every doctor has the right to set a limit to the number of patients he is prepared to accept on his National Health Service list. He has the right, that is, to set a limit to the numbers that his own circumstances permit him to attend as public patients. It must be remembered that within the service all receive equal treatment according to their medical needs. It is impossible for the doctor—or indeed for the Government or the administration—to give any public patient advantages or privileges not enjoyed by the others. It must never be overlooked that there is a grave shortage of doctors and facilities.
4. The profession will feel strongly, the association is confident, that although a doctor is fully entitled to decline to undertake work for which he has no special aptitude, it would be entirely wrong for him to discriminate against particular classes—e.g., to refuse to accept as patients children or old people on the ground that they involve too much work. This is regarded as contrary to the standards of medical practice.

---

[1] *Lancet*, July 24, p. 163.

seem to be that if the public-health services need increased numbers, efforts should be made to recruit and provide training as "health teachers" for the many intelligent girls interested in "social work" or "community service" who have no wish or vocation to take a full training in the nursing of the sick. These could be complementary to the health visitors who are qualified nurses.

(B.) The fact that more than a third of all those who complete training go on to the midwifery course invites the question whether it may be too readily assumed in some hospitals that this is obviously the next step, even for those who intend to remain in hospital posts. A staff nurse in a general ward does not need to have had midwifery training, nor do the sisters in male and some female wards. A nurse who has taken midwifery training after general may not be willing to return to a staff nurse's post, whereas a year or two at least in that capacity might have fitted her much better for a ward sister's post, or indeed for many other posts of responsibility. The way would still be open for her to take midwifery training later if she wished to do so. It might be well for hospitals to put this point of view before student nurses during their training—experience at the Nursing Recruitment Centre shows that many of them apply as early as their second year for places in midwifery training schools. It might also be well to ask the midwifery training schools, which have long waiting-lists and a surplus of candidates to give precedence, to those candidates who have had some hospital experience after training, rather than to book student nurses for vacancies a year or two ahead.

(C.) The proportion giving up nursing altogether is high; but it must be noted that the majority leave to marry—a reason to which exception cannot be taken. It does suggest, however, that much more effort should be made to retain the services of those married nurses who wish to work outside their homes. At present they are allowed to drift into other employment—as receptionists, clerks, &c.—where their nursing training is not put to full use.

Nor can serious exception be taken, in present circumstances, to the number giving up for home reasons, though possibly some of them might be retained for hospital service if non-resident posts with "office hours," in outpatient or other departments, could be had at their local hospitals.

Probably most of the 78 whose reasons for giving up are not known drift into other occupations offering less responsible work and requiring less effort. This would raise the "other occupations" group to about 20%. It is known, for instance, that many young nurses seek secretarial or receptionist posts: indeed, one hospital which sought to economise the time of its nursing staff by appointing outpatient clerks or receptionists found that a number of nurses applied for these posts. It is well worth considering whether this shrinking from responsibility or full endeavour may be due to the almost universal lack of preparation for ward sisters' posts and the example of those who have been appointed to them unprepared, with resultant strain and waste of effort. There must be some deterrent factor at work to cause so many nurses who have just achieved their professional qualification to turn away from the very work for which they have been training. If they could be given a long holiday, and could know that if they return to a staff nurse's post they would be able after a year or two to take a short course in preparation for ward sisters' duties, many might be encouraged to remain in hospital, where their services are needed so urgently. Courses of this kind, available throughout the country without payment of fees, might well become an important factor in building up the permanent staff in hospitals.

CHILDREN'S CINEMA CLUBS

(FROM A CORRESPONDENT)

ON Saturday mornings thousands of children go the cinema. They are glad to go, and their mot are presumably glad to know they are enjoying themsel somewhere out of harm's way—and out of ever else's way too. This would hardly justify the however, if the children were given only trivial or p debased entertainment which did them more harm good. The work of the Children's Ent Film (C.E.F.) section of Gaumont-British Instruct Ltd., is therefore important.

This group, set up in 1944, is responsible for pr children's films, primarily for the Odeon and Gaumo British Junior Cinema Clubs, but also for other childre film clubs and for private showing. The Odeon Gaumont-British clubs—of which there are 400 in G Britain—were launched by J. Arthur Rank in 1 and they have a membership of 400,000 children the ages of seven and fourteen. But there are some other cinemas in the country, many of which Saturday matinees for children, and the standard these varies with the interest of the managers, high in some, low in others.

C.E.F. are guided by an advisory council on which representatives of the Minister of Education, the Ho Secretary, and the Secretary of State for Scotland, of national bodies interested in children's leis Members of this council visit different parts of the country and discuss, with teachers and youth leade the production of special films for children. The fil are initiated by C.E.F. and made under their supervisio by various independent companies.

There is thus good machinery at work to ensure that the children belonging to the junior cinema clubs see suitable films; but as yet the pool of films is small, and programmes sometimes have to be eked out by material which is not quite appropriate. An account of a recent programme in a country town in the Hom Counties serves to illustrate this, and also to show how the clubs are run.

A CLUB IN ACTION

Each junior club has its children's committee, elected by the children themselves, and representing different ag groups. The members of this committee act as steward and are responsible for the orderly behaviour of the c *members as they enter and leave the cinema.* The stew wear armlets denoting their office, and on the occa mentioned were successful in maintaining very good or The clubs work in association with the Royal Society for Prevention of Accidents, and as the children were coming music was playing and the screen showed safety-first mott and advice on the crossing of roads.

The programme opened with some community singing by the assistant manager of the theatre, and this was follow by a film of Sandy Macpherson at the organ also lead community singing. This film, intended for adults, was really successful since the songs were somewhat inappropri *Arrangements had been made to cut one sentimental song,* it appeared none the less; and this seems to be a difficul distributors, it seems, are often careless about making outs ordered.

The "club promise" followed. Standing, and in uni the children promised to follow various social lines of cond —to be kind to animals, and helpful to old people, to o their parents, and to try to make this a better country to in; and if the last seemed a heavy, and the penultimate impossible, undertaking the children at least were untrou by doubts: they promised with gusto.

Next came two cartoons—one a very good *Donald D* The other, a not very successful piece of anti-war propagan was on trial, and was judged unsuitable for general show An episode in a serial specially (and well) made for childr a splendid nature film about otters, and a very good feat *The Little Ballerina*, completed a programme in which standard of taste was on the whole very high, and instructi *agreeably camouflaged. Deathlike silence during the* showin broken by laughter and gasps in the right places, showed th the entertainment value was high too.

Among films lately produced for C.E.F. are a series five by General Film Distributors called *Pen Pictu from Rhodesia.*

creamery could not have been accepted as drinking-water for a village or a town. The finding of fæcal *Bact. coli* in one of the samples of water taken in the washing machines showed that *S. paratyphi* B could have passed into the bottles.

With such a system for the treatment of water as was used in this creamery any failure, for however short a period, would produce the gravest of risks, since a few drops of contaminated water containing paratyphoid bacilli could be left in the bottles. Consideration of the capacity of the storage tank and the hourly consumption of water shows that, though on the average the period of contact with chlorine was over an hour, this period must have been liable to great variations, since water was constantly running in and out of the tank. There would be periods of very special risk when the pumps were started up after an idle period and the storage tank was empty.

It was not until late in the year that the possibility that the paratyphoid fever was milk-borne was entertained. Since the 55 cases were notified in twelve different local-authority areas, it did not at first appear clear that a milk-supply was the probable source of infection of all of them. When the cases in the whole area were reviewed, however, it became evident that some definite inquiry into the possibility that the pasteurised milk consumed by the patients had a common source was called for.

That the epidemic was not much more serious was indeed fortunate, when it is considered that 200,000 persons regularly consumed milk from this creamery, including the pupils of 230 schools.

The incidence of paratyphoid fever in the two counties in the previous six years was studied, since the pasteurisation plant had opened in 1939. It was found that in the summer of 1941 there was an epidemic of paratyphoid fever with exactly the same distribution as that in 1946. There were 76 cases notified in 1941, including 15 recorded as "enteric" without further details. Of the 76 patients 49 lived in the three valleys where most of the cases occurred in 1946. The ratios of the numbers of cases appearing in the three valleys to the total number of cases in the two counties during successive years were as follows: 1940, 7 out of 30; 1941, 49 out of 76; 1942, out of 12; 1943, 7 out of 11; 1944, 1 out of 3; 1945, out of 12; and 1946, 41 out of 55. A retrospective examination was made of the records of the cases occurring in 1941 in the local-authority area where the creamery was situated. There were 13 cases (12 were notified in one month), and 8 of the patients received milk from the creamery, whereas 5 did not. It was impossible to trace the ultimate source of the milk-supply of the 5 patients who gave no history of drinking the suspected milk, as was done in 1946, but 3 of these patients were boys who bathed in the river which flowed by the creamery.

We wish to thank many medical officers of health and officials at the creamery who provided us with every facility to inquire into the outbreak; Dr. M. T. Parker, of the Public Health Laboratory Service, for providing us with the details of cases in his county; and Dr. A. Félix, F.R.S., for typing all the strains of paratyphoid bacilli.

London's Water-supplies

IN their report[1] the Departmental Committee on Greater London Water Supplies recommend urgent inquiry into resources and prospective demands throughout the area. At the same time, says the report, plans should be prepared for a new major source of supply, which will be needed in the not very distant future.

The committee agree that the resources of the area must be treated as a whole, and that the community of interest in the area and the geological unity of the Thames basin demand the pooling of all resources and the treating of water problems in coördination. They also agree that a central water authority is necessary, and that the cost of the new major source of supply should be borne by the whole area. But the committee are unable to agree on the method of administration, two members favouring a simple "all-purpose" authority for the whole area, while the other three consider that there should be four joint boards, with a central water authority to coördinate the use of the internal resources of the area and to develop the new major source.

In the Metropolitan Water Board's area, during the year ended March 31, 1947, the average daily consumption per head for all purposes, including industry and public uses, was 51·8 gallons; for the surrounding area the comparable figure was 39 gallons. This consumption, it is felt, will certainly rise, largely owing to: (1) the higher standard of water services in modern houses; (2) increased demands by industry and for the new towns; (3) district heating; and (4) the extension of water-supplies in rural parts. The committee estimate that allowance should be made for an eventual daily consumption per head of 60 gallons in the Metropolitan Water Board's area and 50 gallons in the outer area. It is suggested that by 1960 Greater London's total requirements will be of the order of 670 million gallons a day. Even after completion of new reservoirs at Wraysbury and Datchet, in a drought year similar to that of 1944 there would be a deficiency of at least 10 million gallons per day.

Utilisation of Vitamin Supplements

In a recent number of the *Medical Officer*,[1] Dr. Joseph Berkeley draws attention to wastage of Government vitamin foods. Investigation at infant-welfare centres showed that in the Kendal district about half of the orange juice and a third of the cod-liver oil is not consumed after purchase; and of 87 mothers with infants aged between 2 months and 12 months, 44 (50·6%) had discontinued the giving of orange juice, and 28 (32·2%) had discontinued cod-liver oil. The reasons given by the mothers related mainly to the child's intolerance of these foods. Dr. Berkeley concludes that the true proportion of infants who suffer digestive disturbances from this cause is less than the mother's answers would suggest; but nevertheless, he adds, consideration should be given to replacing the present preparations by others more palatable and better suited to infants' digestive capacities.

PUBLIC HEALTH LABORATORY, CARDIFF

IN a county with a population of about 1,000,000 there were 48 proved cases of paratyphoid fever in 1946.

In the north of the county are several densely populated valleys, and 28 of the patients lived in one valley; 7 came from the neighbouring valley to the east; and 6 from the valley to the west. The remaining 7 cases were scattered throughout the northern and western districts of the county. Of the 48 patients 30 were females, 31 were under 18 years of age, and 22 were under 10 years; 3 were accepted as secondary cases. All the cases were notified in the latter half of the year, but most occurred in August (21 cases) or in the first half of November (12 cases), and it was not until the second wave appeared that a connecting link between the cases which occurred over a wide area was discovered.

At this time a review of the information relating to the cases in nine different local-authority areas showed that many of the patients consumed pasteurised milk, the original source of which was not always stated. Further investigation showed that all the pasteurised milk concerned was traceable to one creamery. There were still, however, some children who did not consume pasteurised milk at home. Investigation showed that they received the suspected pasteurised milk at school. All except 3 of the 48 cases gave a clear history of regularly drinking the milk from the same creamery, which was situated in the valley where most of the cases occurred, and the distribution of the cases followed closely the distribution of the milk.

Further evidence in support of the theory that the infection was spread from this creamery was obtained from a neighbouring county, where 7 cases of paratyphoid fever were notified in the latter half of 1946, in all of which the patients had partaken at home or at school of the suspected milk. The cases appeared in three local-authority areas with a total population of 83,000, yet only 500 gallons, a small fraction of the total milk consumed in the area, was received from the suspected source.

INVESTIGATION OF THE CREAMERY

The creamery pasteurised daily 15,000 gallons of milk, and inspection of the plant and records showed no evidence that the heat treatment had been inadequate. The main source of water from the creamery was a nearby river, from which 3000 gallons was drawn hourly. Chlorine, to produce a concentration of 2·5 parts per million, was injected by an automatic pulsator into the crude water, which was then passed through a Candy pressure filter to an elevated storage tank of 5000-gallon capacity. From the tank this water passed to the bottle-washing machines, where, after the initial cleansing with hot detergents, it was used for the final rinsing immediately before the bottles were filled with pasteurised milk. The bottles were rinsed both inside and outside as they passed inverted on a conveyer system. Samples of this water had often been taken from the jets of the bottle-washing machines for examination in the creamery's laboratory, and readings of 0·3–1 part of residual chlo per million were usual, but occasionally much lo readings were obtained. Bacteriological examinati had been made periodically, and presumptive colif bacilli often found. When difficulty was experien in maintaining a supply of chlorinated water ei because chlorine was not available or because of a bre down in the pump house, a supply was obtained f the local mains, but this too was led to the storage t already mentioned. Such a temporary change in wa supply was common, being made on nine occasion 1946.

The river water was heavily contaminated with sewage of several towns higher up the valley, and a san of water collected near the intake to the crear yielded more than 18,000 presumptive coliform ba per 100 ml., more than 1800 fæcal *Bact. coli* per 100 and *S. paratyphi* B of the same bacteriophage typ that responsible for all the cases (phage type 1). Sam of river water taken over several weeks yielded *S. p typhi* B on three out of four occasions.

The constancy with which paratyphoid-B organi could be isolated from the river near the intake to creamery was surprising, because the river had a c siderable flow, estimated roughly at 2,000,000–3,000, gallons an hour. On investigation of the sewage charging into the river higher up, however, a sm examination of each of three outflows from separ towns yielded *S. paratyphi* B type 1 six months a the last case of paratyphoid fever had been notified.

Several samples of the chlorinated water were ta by us from the jets of the bottle-washing machines, a from one of these fæcal *Bact. coli* was isolated (1 100 ml.). Tests for presumptive coliform bacilli w often positive, but this result was due to clostridia, probably the presumptive coliform bacilli found pre ously in samples examined in the creamery's laborat were mostly clostridia. The presence of only a presumptive coliform bacilli (1 to 4 per 100 ml.) had b accepted in the past as evidence of the efficiency of plant and of the purity of the water. Tests for fa *Bact. coli* had not previously been made.

Examination of the workers in the creamery did reveal any carrier of *S. paratyphi* B.

After the use of the river water had been discontin only 4 cases of paratyphoid fever were notified in county in the next year. One of these was found t excreting *S. paratyphi* B phage type 1 from a drai gall-bladder after a surgical operation. There was evidence that this patient had recently acquired infection, and she may have been an old carrier. of the remaining three cases were in nurses who atten this patient. The last case was a girl who gave no hist of having had milk from the creamery.

DISCUSSION

Milk-borne diseases are not always readily recogni In some cases an explosive outbreak affecting yo persons may reveal the source of the infection imm ately, but many outbreaks producing a few cases spr over a considerable time often pass unnoticed.

So far as we can ascertain, this is the first record o outbreak of paratyphoid fever in this country spread pasteurised milk, and the experience shows the imp ance of making a careful check on all the processes pasteurisation plant and not merely on the ac heating of the milk. In this outbreak the milk was infected in the processing chambers, but appare only occasional bottles were contaminated by the w from the jets of the washing machines. It was cle possible for such a method of infection of the m supply to account for only 55 cases in six months. W used to rinse bottles before they are filled with should be a potable water, and the water used in

Letters to the Editor

THE TWO PATTERNS

SIR,—The Spens report on the remuneration of specialists speaks of

> "The intention underlying the National Health Service Act that in the hospital system of the future there should be a more uniform level of hospital efficiency throughout the country, a better distribution of specialists, and permeation throughout the hospital service of each region of the influence of the university centre. These objects can be achieved only by increasing the mobility of specialists throughout the service and facilitating the interchange of staffs between teaching and non-teaching hospitals . . . it is obviously important that the status of the area hospital centre should be in no way inferior to that of the teaching hospital, and that both should be able to attract specialists of the highest calibre. We are therefore of opinion that the same range of remuneration for clinical work should apply to specialists in both teaching and non-teaching hospitals."

The question immediately arises, will this be enough by itself to bring about equality of status between area hospital and teaching hospital? Does anyone believe that a mere levelling of income will bring this about? If anything will it not make the competition to remain at a teaching hospital even more intense than it has been? The best men have seldom cared mainly about money; their work and the conditions affecting this are what have mattered most to them. They have in the past accepted low pay, financial insecurity, and no guarantee of eventually getting on to the staff, for the privilege of working at a teaching hospital with its atmosphere and opportunities.

Clearly some more radical change is needed if the area hospitals are ever to achieve "equality of status" with the teaching hospitals. More circulation of staff—and this will be far more difficult to secure in practice than on paper—will not be enough. Can one readily imagine a specialist on the staff of a teaching hospital being willing to transfer to an area hospital as these have been organised? Surely if we are ever to see the interchange of staff between area and teaching hospital, and real equality of status between them, they must have roughly the same kind of organisation and internal administration, ensuring to their staffs the same conditions of work and a similar share of responsibility for the welfare of their hospitals.

We are fortunate in this country in that for many years an experiment has been going on in which two very different types of internal hospital administration have been used—i.e., that of the teaching and voluntary hospitals and that of the county and municipal hospitals. In the former the medical staff committee had considerable power and responsibility, especially in the teaching hospital, and worked through a hospital administrator—usually lay—who was the servant and executive officer of the committee and of the corporation; in the latter the administration was in the hands of a medical superintendent, and if a staff committee existed its function was purely advisory.

The standard of hospital practice with the exception of the care of the chronic sick and of the aged—in which the municipal hospitals have a unique experience—has been set by the teaching hospital. Clearly these have succeeded not only in attracting the best men but in providing them with conditions for fruitful work. Why has this been so and what are the secrets of their success? As you pointed out in your leading article of July 17, staff selection is a question of "truly fundamental importance." But in addition to exercising great care in the selection of staff (and this was almost entirely in the hands of the medical staff itself) there were other practices common to them all—i.e., complete clinical freedom, the presence of students, the prosecution of research, and the assistance of a powerful medical committee which in fact ran the hospital and school and was the custodian of its traditions.

Has not the time come to examine the organisation, methods of internal administration, and practice of the teaching and of the municipal hospital, to decide in the light of experience which methods give the best results, and to adopt these as far as possible for all large general hospitals? Would not this be the most practical way of ensuring real equality of status, and incidentally would it not reduce the need for interchange of staff between area and teaching hospital, while in fact making such interchange easier? The traditions and esprit-de-corps of the teaching hospitals have been a tremendous factor in their success. We must foster the growth of these essential imponderables in the area hospitals if the intention of the Act is to be translated into reality. What better or more tested method of doing this than by giving the staff of these hospitals a real and important share of responsibility for their welfare and development?

Richmond, Surrey. E. A. DEVENISH.

PAIN

SIR,—In spite of my giving a definition of psychogenic pain, when using the term in my paper on pain charts, misunderstanding seems to have arisen. I have not tried the pain-chart technique on psychoneurotics—only on normal persons. These may experience psychogenic pain. The "irregular" nature of such pain is in response to stimuli and analgesic drugs—not merely arrhythmic as Dr. Lowy interprets it in your issue of July 10.

Dr. Barton Hall (July 17) suspects me of psychological philistinism; but he fails to notice my definition of psychogenic pain, and consequently proceeds to tilt at windmills with quixotic fervour. Let me repeat: I am not describing psychoneurotic patients. Every physician and psychiatrist must be aware of patients with true anxiety, experiencing pain as a symptom; cases were plentiful during the war. Such persons are amenable to suggestion and reassurance early, but can be turned into psychoneurotics by mismanagement, especially if of unstable personality. Such a situation may be produced by organic disease, and must be assessed. It is here that the pain-chart technique gives information which is useful in management of the case, as described in my paper. Let me assure Dr. Barton Hall that the psychological aspect of the case described was considered; the brief résumé submitted was designed as a background to the pain chart, not as a full and irrelevant clinical and psychological case-history.

Pain charts of the type illustrated are commonly found in persons with pain "which has little or no organic basis, and is maximally influenced by suggestion"—i.e., of "psychogenic" as opposed to "organic" origin. In the context of assessing the response to analgesic drugs this fact is of prime importance. I have emphasised that in many patients with cancer or coronary-artery disease there is response to distilled water (see chart 7), and that in the management of cases the assessment of this factor is of considerable value. Such assessment is of course, made in conjunction with the rest of the clinical picture. I see no reason at all for the perpetuation of the abuse of the distilled-water test "as a diagnostic refuge" for housemen as suggested by Dr. Barton Hall. However, I am concerned to prevent doctors tricking, not only their patients, but themselves in the use of analgesic drugs.

Dr. Pinoff (July 24) discusses the interesting factor of pain sensitivity. I have given much attention to this, but have obtained no evidence of rapid oscillations in normal persons. Chart 4 in the paper is a record of untreated pain, such as he asks for, in which it will be seen that a similar stimulus at different times produces similar response. However, during the experience of pain, sensitivity is decreased. Counterirritation by blistering, &c., depended on this fact for its questionable benefits. Shakespeare describes it with beautiful accuracy when he says: "One fire burns out another's burning. One pain is lessened by another's anguish."

Dr. Craig (July 31), like Dr. Barton Hall, having ignored my definition of psychogenic pain, plunges deep into the obscure depths of the "bad" word (without defining it), and emerges ascribing to me "views" on subjects that I cannot find mentioned in the paper. The pain chart records pain alone, not the underlying

In England Now

A Running Commentary by Peripatetic Correspondents

THE inhabitants of Henley-on-Thames are used to seeing magnificent young men with all shades of sunburn, clad in exotic variations on the zoot-suit (if that is how you spell the garments skiers wear). But this year's gathering of the rowing men of 27 nations for the Olympic events—the royal blue and white of Finland, the port-wine of Portugal, the red, white, and blue of Great Britain, the scarlet of Canada, the green of Ireland, and so on—has put even regatta week in the shade.

The weather has been beastly: mostly drizzle with occasional showers. Except for the last afternoon, when summer returned with a bang, and even the vast open stand (3000-odd seats at 30*s.* compared with 25*s.* in the covered stand) was crowded. On Saturday morning, when the towpath crowd were yelling like mad over the victory of Risso of Uruguay, the clouds opened, and for five minutes we cowered under whatever shelter we could find, to emerge chattering like monkeys. For Risso, an "outsider," had done the impossible. Many lengths behind John B. Kelly, jun., of the U.S.A., famous son of a distinguished Olympic sculler, he had spurted when most men would have given up hope, to win by inches. On Saturday afternoon the sun shone while we worked the family skiff on to the booms to see the British eight and double-scullers qualify for Monday's finals. But on the whole the boatmen have worn long faces and only the plutocrats in the covered stands have kept dry. The high spot, I think, was watching the starts on the first morning, when only a few foreign officials were present. With the starter calling "Messieurs! Êtes-vous prêts? Partez!" and the coxes of Portugal, Greece, Yugoslavia, Hungary, and Italy yelling as no Anglo-Saxon could do, we felt we were taking part in a truly international affair.

* * *

Two things immediately strike the visitor who has previously lived here long enough to lose his astonishment at skyscrapers, spittoons, and the New York summer. These two things are the price of food, and the connotation of the word communist.

Don't let anybody tell you that the end of price controls stopped rationing here; it merely shifted a certain number of citizens out of the rationing bracket and reduced the rations of others. Meat prices are the highest; you pay in strict proportion, it seems, to the amount of useful amino acids ingested. Prices vary, of course, across the continent and by localities, but the following are representative of the East Coast and a lower middle-class district. Steak and lamb chops are 6*s.* a lb., pork chops (in bygone days the staple food of many a Negro janitor and many a medical student) 4*s.*, and chicken 3*s.* Butter is 5*s.* a lb., eggs about 4*s.* 3*d.* a dozen, milk 6*d.* a pint, fish around 3*s.* to 3*s.* 6*d.* a lb. It took me longer to extract from the young commercial traveller, who rents the basement of the house where I am staying, information about the dietary he and his wife follow than it did for him to tell me that mine was at starvation level; but I finally discovered they had meat once or twice every fortnight. An old friend who had been at medical school with my wife, and whose husband was also a doctor, was more forthcoming. Both were relatively new in practice, and still in the mildly struggling stages—in their middle thirties, in other words. They very seldom had steaks or chops, though they managed meat meals of a more English type about three or four times a week, with chicken once or twice: the yearly food bill for three adults and three children was £500. Wages and earnings are, of course, somewhat higher than in England—in the academic medical world just about 25%. A professor of physiology gets £2000–2500, an associate professor (reader) about £1500–2000, an assistant professor (lecturer) £1000–1250. Probably, with cars, refrigerators, radios, and many household goods below English prices, food above it, and rent and entertainment not too dissimilar, the standard of living of British and American counterparts is about the same, at any rate below professorial level. The G.P. on the average lives better, I would say, since (as in England) he can generally expect to earn more than a professor. In other wo the rich (and this includes the £8 a day visiting busi man) do all right: the poor—well, they gripe like n the ones I've talked to, but more about the Russi and, in New York, the British, than about food prices those who play the food markets.

The *New York Times* has published a chart dr by the State Labor Department dealing with the tr of weekly earnings, actual and real, for 900 New York City manufacturing workers. Since beginning of 1945 the price index has gone up 30% actual wages 16%: real wages have come steadily d and are now at the level of February, 1943, a midway p in the armament boom from January, 1941, to the of March, 1945. Inflation here is a familiar word, every person I have asked expects a depression, s tacular or minor (but mostly the former) within t years, "unless," add a good 50%, "there is a war fl

Events in Berlin and the activities of the Cong investigators of men such as Dr. Condon, the em physicist, get inextricably mixed in the many peo minds. Among the majority of social and educati strata in New York City (by and large a liberal strongh it is not an exaggeration to say that anyone holdi political or economic doctrine departing from the clas conception of laisser-faire is called a communist. looks as though this country is getting set for a witch-hunt. And at the same time there is a frightening sentiment widespread amongst the peop have talked to: it is akin to that of the British in and 1939—"let's get it over with: anything is be than this business of not being allowed to live in pea

Being married to an embryo psychiatrist my takes her job very seriously, so her embarrassment be imagined when, coming home unexpectedly the o afternoon, I overheard her in the garden furio shaking our two-year-old, above whose screams could distinguished, "I don't care two hoots what this does *your* complexes; all I know is that you're absolut ruining *mine*."

tact, as well as skill in shorthand, typing, bookkeeping, and filing.

Why does not the Ministry of Health set up a training-school for medical secretaries, who are after all very necessary to the efficient running of hospitals? If, after learning shorthand and typewriting, girls could receive training in elementary physiology (to give them a basic knowledge of what they are doing), simple instruction in the various branches of specialist medicine. practice in taking technical reports and keeping medical records, and even some practical training to enable them to assist in hospital departments or in a private surgery, followed by examinations and the award of diplomas, the medical secretary would then have a recognised place in the medical world; and the standard of work. particularly from stenographers taking reports. would improve accordingly.

MEDICAL SECRETARY.

PROFESSIONAL SECRECY AND VENEREAL DISEASE

SIR,—At the end of last year[1] you were good enough to allow me to draw attention to breaches of professional secrecy which doctors found themselves compelled to make by Government departments. notably the Ministry of Food. The position of doctors under the National Health Service Act is rendered still more invidious by S.I. 506 and 507 (March 24. 1948) which compel the general practitioner to submit his medical records of public patients under his care to the inspection and even to the custody of two bodies: (1) the local executive council, and (2) the (local) medical services committee, the first consisting of 50% lay members. and the second of an actual majority of lay members. including the chairman. Concurrently with these developments. and in the same unhappy direction, a breach has been made in a practice which has enjoyed statutory authority for thirty years. By the operation of the Bevan Act. the Public Health Venereal Diseases Regulations, 1916, have been revoked, and with this revocation, the statutory requirement that all information obtained about persons under treatment for V.D. shall be confidential has been withdrawn. Unhappily, the motives underlying these new arrangements would seem to be that scrutiny of records is demanded by the economic pressure to reduce to the lowest possible level the actual disbursements for benefits and services promised by the N.I. and N.H.S. Acts.

There have long been two schools of thought in this matter of dealing with venereal diseases—the school which clamours for their notification, and the school which pleads for the maintenance of absolute confidentiality. A trial of strength between these two views was staged in an important debate in the House of Commons on April 19, 1928, on a Bill presented by the Edinburgh Corporation calling for their compulsory notification. Mr. Pethick Lawrence, as he then was, proposed a motion which I seconded. resisting the demand for notification. The weight of opinion was strongly against any relaxation of the statutory requirement quoted, and the Edinburgh Bill was defeated by a large majority. I believe that since then the practice has been universal in V.D. clinics by which the patient seeking advice and treatment is given written assurance that no disclosure shall be made of his disorder. and that a number shall be substituted for his name on any records made.

I submit, Sir, that in present circumstances, when venereal disease has been classed, as in a recent broadcast, among the four diseases which are now most destructive to humanity, any suspicion of relaxation of secrecy is to be especially deprecated.

House of Commons. E. GRAHAM-LITTLE.

SIR,—For over 30 years treatment of V.D. in this country has been confidential by custom and by statute. The effect of this, together with the arrangements for free voluntary treatment and careful public education, has been excellent, as the figures of attendance at public clinics show.

The principles that treatment shall be free and that it shall be voluntary, which were secured by regulations in 1916, are included in the new scheme; but the important and necessary requirement of confidence, on which all British V.D. treatment has been built and on which all public propaganda is based, is left out. No explanation has been given, nor have any satisfactory replies to Parliamentary and other questions been received. The Minister has said that he hopes confidence will be maintained as before: and no doubt doctors, nurses, and administrators will do everything possible to observe this. as in the past. But his hopes cannot have the same power and efficacy as a legal requirement.

The amendments to the N.H.S. Act which are now being drafted will presumably rectify the omissions and ambiguities of the Act. It is to be hoped that the medical profession and all who are concerned with the treatment of patients and administration of clinics and hospitals will urge the Minister to restore the requirement that (to quote the revoked 1916 regulation) "all information obtained in regard to any person treated under a scheme approved in pursuance of this article shall be regarded as confidential."

KATHARINE B. HARDWICK

Livingstone House,
Broadway,
London, S.W.1.

General Secretary, Association
for Moral and Social
Hygiene.

HEARING-AIDS

SIR,—May we through your columns make clear the position regarding hearing-aid supplies?

We are receiving a considerable number of callers with E.C.10 prescriptions. some of which are specifying that the patient be supplied with a "National hearing-aid"; others prescribe that the patient's existing hearing-aid shall be repaired under the health scheme. and still others call for supplies of hearing-aid batteries.

The Government has chosen to leave hearing-aid manufacturers such as ourselves outside the scheme, and therefore we are not in a position to accept prescriptions for any hearing-aid supplies other than those for which the patient is prepared to make payment. It seems unfair that existing users of hearing-aids are not to get assistance towards maintaining their instruments, but it remains for the deafened public to make representation in the proper quarter if they wish to get this apparent anomaly rectified.

Oxford. JOHN BELL & CROYDEN.

REPEATING THE PRESCRIPTION

SIR,—In the National Health Service, as you say,[1] "Private patients who formerly had repeat prescriptions filled by pharmacists now come to have each prescription written on to the official form; . . ." And the extra labour involved has been mentioned among reasons for staying out of the service.[2] May I put the other side?

In the first place, the reputable practice of medicine insists that patients should not be treated without supervision. On the whole, the most reputable type of practice relies on the maximum of supervision with the minimum of medication. and the old National Health Insurance very rightly protected patients from the least reputable type, which is medication without supervision.

In the second place, the amount of drug prescribed rested with the doctor's discretion, as it does now. One could prescribe, say, 200 digoxin or phenobarbitone tablets. to last 2–3 months, if one felt that the patient would be likely to flourish on these unsupervised. Liquid preparations have an additional limiting factor in the size of the largest available bottle, but a three months' course of iron in liquid form could still be ordered on a chain of antedated prescriptions—if one were determined not to see the patient during that time. So far as I am aware. all this can be done still.

In the third place. even the private patient was, and is, protected from indiscriminate drugging, in so far as the Poisons Schedule stands between him and his (or his doctor's) folly. Now, as before, the chemist is obliged to keep prescriptions with scheduled drugs, and to obtain the doctor's permission before dispensing the same drug again. This arrangement is intended to

disease, in the same way as a temperature chart records body temperature only. Interpretation of such charts is a separate part of diagnosis; the chart itself is purely descriptive. However, just as a temperature chart may legitimately suggest a diagnosis of typhoid fever, so may a pain chart amplify history-taking and convey information regarding the psychogenic or organic nature of the pain.

Staines. K. D. Keele.

CARS FOR DOCTORS

Sir,—Your correspondent "Waiting-list" (July 31) wrote as follows: "To wait until the car will not go at all, and will therefore pass muster as 'unserviceable,' is obviously fantastic."

Fantastic, but fact these days. My own car, 1938 model, has given all the symptoms and signs of one or more worn big ends for the past two months. My garage, a large firm and the local agents for this make, assured me that spare parts were unobtainable, as were any reliable reconditioned engines for this model; they arranged to have the engine in August, for the parts to be made and the crank reground. However, the big end broke and the car jammed immobile ten days ago. Since then I have been unable to hire or borrow a car.

Improvident? I do not think so. In March, 1946, when my release from the R.A.M.C. was imminent, I ordered a new car. I am still awaiting delivery, and the distributors cannot even now tell me when I am likely to get it. In the circumstances I had to buy a second-hand car to start practice, and though this car served me well mechanically it meant that: (1) I had a serviceable vehicle and so lost my "really early date" for delivery; and (2) my new car will cost £1080 instead of £680—the price when I ordered it. No firm had any cars to hire before early October, and the firm offering one then quoted the price as 22 guineas per week, including petrol.

My patients are visited by taxi in the day or on foot or *bicycle at night. The expense is nothing* compared with the pitfalls of buying another second-hand car and having another "serviceable" car.

Hildenborough. C. Glaisher.

EPIDEMIC JAUNDICE

Sir,—The interesting papers[1] and your leading article[2] on the sequelæ of epidemic jaundice, prompt a note on the following case:

In the winter of 1945–46 a physician, aged 55, in civil practice had a moderately severe attack of "infective hepatitis." The infection was possibly derived from among Servicemen who attended outpatient clinics for consultation. They included soldiers from Italy and Africa and prisoners-of-war.

The onset was insidious. In November the patient had a mild rigor followed by a few days of fever. In December there was a second bout of fever associated with "fatty diarrhœa." During January he became emaciated: ascites and œdema of the feet developed, and fever continued with profuse nocturnal sweats. Jaundice appeared late (at the end of January) and was slight, affecting the face and upper limbs more than the trunk and legs: absence of bile from the stools and biliuria were of much longer duration than the jaundice. The liver became grossly enlarged, reaching below the umbilicus, with the right lobe touching the iliac crest; the spleen was never palpable. Recovery was slow, a mild pyrexia (night reading 100°F) persisting until the middle of April when observations were discontinued; the *liver gradually diminished in size and signs of obstructive* jaundice disappeared. In September he appeared perfectly well and was able to walk and swim as usual during a holiday at the Lakes.

The first relapse occurred in February, 1947, after a night journey to Scotland in an unheated train. Mild fever and signs of hepatic obstruction developed, with nausea and anorexia but no jaundice. *The liver again became enlarged* almost to its former dimensions. This attack was not so severe as the first, and by July recovery was apparently complete. There was a third relapse or recurrence in December, 1947, which began with vomiting and fatty diarrhœa. The enlarged to a lesser degree than in the first and second at and there was no jaundice. At the end of June this he was free from symptoms but the liver was still pal two finger-breadths below the costal margin.

The pathology of the liver can only be surmised the absence of liver puncture or functional tests, but remarkable variation in size is difficult to correlate *cirrhosis or partial necrosis. Is it due to the* "clo swelling" of the morbid anatomist superimposed o cirrhotic liver? The relapsing type of infective hepat is recognised, but this case differs from most of t recorded in that the original attack and each of the t relapses have been progressively less severe, w apparently complete recovery. With regard to suggestion of hepatic neurosis following hepatitis, t patient has developed a distaste for fried food and m fat; he is now sensitive to cold, and especially to c winds to which he was *formerly* indifferent.

A last point may be made concerning the treatment infective hepatitis. Rest in bed and high protein are considered essential. This patient continued work during the first attack though his activity curtailed partly by difficulty in walking or going upst. He had a fortnight's convalescence three months a the onset. In the subsequent relapses he has contin to work as usual. It is difficult however to see how t régime can have influenced the relapsing course of illness.

The Victi

MISTAKEN DIAGNOSIS OF CANCER

Sir,—As Mr. Justice Birkett's decision is disquieti to the medical profession, so are your comme last week disquieting to patients. Having stated t position definitely that "to omit to use all proper a accustomed aids to diagnosis is obviously a breach professional duty" you then try to escape *on the "no-o* can be infallible" plea. Surely a pathological report an essential for the diagnosis of a malignant growt In a cancer hospital I was assured that such a rep is routine. The difficulty had been to believe the accur of the newspaper reports that the surgeon had b guilty of such an omission; now The Lancet re confirms them.

Even with confirmation from the pathologist, h far is a surgeon justified in telling a patient that he only live a short while? It is time that our statis were reorientated on a health basis. The number people who are alive when according to medical op they *ought to be* dead would be surprising.

One of the Dead

MEDICAL RECORDS

Sir,—In reading last week's letter on this subj I was struck by the sentence: "The difficulty of find a good medical stenographer was acknowledged." reason is not far to seek.

Other workers in the field of medicine are recogni —*the nurse, the technician,* the physiotherapist, t radiographer—but not the medical secretary. There no special training for her, and there is little distinct between the secretary carrying a great deal of respo bility and the most junior typist. How would a sis enjoy being treated in the same way as a student n Most secretaries and stenographers who choose a me career do so because they consider it more "sele than commerce, because they think it will be easy, because the work is of absorbing interest to the I think the majority come into this last category, for it very badly paid, often highly responsible, and certai far from easy.

Something should certainly be done about salar Doctors are notoriously mean when it comes to pay their secretaries, but I do not think they really me to be. I think it is because all medical clerical classes *lumped together* rather contemptuously in a doct mind as "typists." A nurse's skill is respected, but secretary is not credited with having any; yet t must be well educated, possess a pleasing personali and have a high degree of intelligence, initiative, a

did not notify the patient; and he did not take any tests.

The M.O.H. next received a letter from solicitors, claiming damages on behalf of the discharged cook on the grounds that the letter written by him to the manageress was libellous, that as a result of it she had lost her position, that she had become unemployable in such capacity, and that after very little investigation the allegation made had been shown to be unfounded. The solicitors also made a claim against the county council.

When the case came for trial before Mr. Justice Maguire on May 3, 1948, the plaintiff gave evidence that after dismissal she returned to hospital where tests were made: the results, she was informed, were satisfactory. She had since been afraid to take up employment as a cook although she had had plenty of offers. Under cross-examination she said that two other employees on the restaurant car to which the typhoid epidemic had been traced had had typhoid.

A doctor gave evidence that the girl was originally in hospital for two months, and was discharged after the usual routine tests. On readmission tests showed that she was over the typhoid and was not excreting typhoid bacilli at the time the tests were made. Under cross-examination he said that the plaintiff could have been a precocious carrier, and that 19 or 20 persons were admitted to his hospital as a result of the Great Northern Railway outbreak. He was satisfied that the overwhelming weight of evidence showed that the infection came from the staff of the dining-car, and his opinion was that the plaintiff was the most likely member of the staff. In his opinion she might have been a precocious carrier and a convalescent carrier. He considered that it would be very risky to have kept the girl in the hotel without a check. He himself had not warned her against handling food, but it was a routine matter that she should be warned by a member of the staff.

The plaintiff, on being recalled, stated that no warning was given to her on leaving the hospital.

In his evidence the M.O.H. agreed that he had not complied with the regulations as laid down. He did not carry out an examination as there was no time to do it: he considered it his primary duty to get rid of the girl as cook. He appreciated that under the regulations his only power was to have the girl removed for a stated period, and that he had not specified any period in his letter.

The chief medical officer of the Department of Health stated that he considered unworkable the regulations in force at the time to which the complaint referred; they had been superseded by new regulations. He thought that it was not safe to allow the plaintiff to work in her position in the hotel.

The jury, having previously given a direction dismissing the county council from the action, found in favour of the plaintiff and to the effect that the M.O.H. had been negligent in the discharge of his statutory duties; and they assessed damages at £750.

The council of the Medical Protection Society, which had acted for the M.O.H., decided that an appeal was useless in view of the finding on facts, and in view of the undoubted fact that despite the medical evidence being in his favour he had exceeded his statutory powers and had by his failure to notify the patient deprived her of the right to compensation.

An Action Dismissed

Two years ago[1] a brief note in this column referred to litigation against Mr. H. G. Bedford Russell in respect of money received from a deceased patient. Sums amounting to approximately £10,000 had been paid to him over two years, and the patient's executor, in taking over her affairs, felt it his duty, in the interests of her estate, to seek to recover the money. Members of the medical profession stand in a special relation to their patients and are exposed in such circumstances to allegations of having exerted undue influence.

The litigation was happily ended on July 29, when counsel for the executor announced that subsequent enquiries had shown that the patient gave Mr. Russell the money not by way of gift but for the furtherance of research into the origins of the sinus trouble (from which she suffered) and its effects upon the mind and body. Steps had been taken to give effect to this charitable purpose by a trust deed approved by the Attorney-General. Mr. Russell's counsel stated that it was reasonable for the executor to have brought the initial action; the executor declared that Mr. Russell had acted in a perfectly proper manner and that all allegations of unprofessional conduct or undue influence were entirely unfounded and unreservedly withdrawn. Mr. Justice Vaisey, dismissing the action and making the appropriate order by consent of all the parties, said the case had served the useful purpose of clearing Mr. Russell of any kind of impropriety, professional or otherwise.

Obituary

CHARLES MATHESON KENNEDY

M.B.E., F.R.C.S.

Mr. C. M. Kennedy, surgeon to the Prince of Wales's Hospital, Plymouth, died on July 26. Although within a few months of retirement, he was still in active hospital and private practice.

Born in co. Donegal in 1884, the son of Dr. David Kennedy, he was educated at Queen's College, British Guiana, and at St. Edward's School, Oxford. At the London Hospital he was an enthusiastic member of the club's union and played rugby for the hospital. In 1906 he took the Conjoint qualification, and five years later the F.R.C.S. In 1911 he became surgical registrar at the London, and two years later he was appointed to the staff of the East London Hospital for Children. His career was interrupted by the 1914–18 war, during which he served as a surgical specialist, later commanding a hospital engaged chiefly in cerebral surgery. He rose to the rank of lieut.-colonel and was appointed M.B.E. On demobilisation he returned to his hospital appointments in London, but when an opening occurred he obtained a staff appointment at the (then) South Devon and East Cornwall Hospital and settled in Plymouth.

Here he led a full life, for besides being a general surgeon he held posts as orthopædic surgeon to the South Devon and East Cornwall Hospital, to the Plymouth City Hospital, and to the Dame Hannah Rogers Hospital for Children at Ivybridge. Though his work was thus largely orthopædic, it was never predominantly so, and his writings were on abdominal surgery. In spite of heavy work he also undertook command of the Wessex Territorial field ambulance, recruited in Plymouth, and he was at various times president of the Plymouth Medical Society and of the South Western branch of the British Medical Association. An excellent committeeman and chairman, he was for several years secretary of the medical board of his hospital.

"Charles Kennedy's surgery," writes H.F.V., "was of a high standard, and he was a leading light in the West Country, where his punctuality and his ability to recollect details of cases will long be remembered. His opinion, whether upon professional matters or hospital administration, was much sought: when one went to him to discuss some difficult problem he would ponder for a few seconds only, and then give an answer which was always well balanced and advice which was worth following. A strong character, forceful but kind, he never hesitated to denounce another's views, and he could be a strong but scrupulously just opponent. Nothing if not honest, he was always a loyal and trustworthy friend."

Mr. Kennedy leaves a widow and four sons.

HUGH COLLIN DAVIES

M.D. GLASG.

Dr. H. Collin Davies died at his home in Colwyn Bay on July 29. He was born in Carmarthen in 1878, and received his early training at the University College, Cardiff, where he held an open exhibition in natural science. After graduating at Glasgow University in 1903 he spent many years in practice in South and West Wales, and during the 1914–18 war he served in the R.A.M.C. In 1925 he took his M.D. and in the same bring doctor and patient together at suitable intervals, whenever anything in the nature of a potent or dangerous drug is in question; it applies to private and public patients alike, and it assumes that doctors are reasonably interested in their patients' welfare. If we don't dispute this, what exactly are we grumbling at? That a smaller number of people than hitherto will be able to imbibe medicines to their hearts' content and without guidance? Or that the State is at fault for refusing to pay for drugs and services the usefulness of which is to be judged entirely by the patient? It seems risky enough to leave it to the judgment of the doctor, if he regards the patient's visit as a tiresome reminder that another prescription is due, instead of as an opportunity to watch progress and change or withold drugs according to the results obtained.

---

[1] *Lancet*, 1946, ii, 31

The number of conditions which need constant medication with relatively innocuous drugs are relatively few—quite certainly not enough to make prescription-writing a nuisance. Where the nuisance exists, the conditions must be absent, and it just shows how wise the State is in restricting malpractice of this kind by discouraging its perpetrators.

PRACTITIONER.

BINOCULAR MICROSCOPES

SIR,—The lessened eyestrain resulting from the use of binocular microscopes has led to their being employed very largely by those of us who have to work with them all day. Until the beginning of the century the Wenham and Greenough binoculars were the only practical instruments of this kind, but they were restricted to low powers, the former (which used one objective) because of the nature of the Wenham prism, the latter because to increase stereoscopy two objectives were used. With the introduction of efficient half-silvered prisms, it became possible to make binocular attachments for the ordinary microscope, all the ordinary powers of the microscope being now usable with them. In spite of the single objective, a considerable amount of stereoscopy is obtainable in this way, and it can even be exaggerated by suitable eyepiece-caps.

In the Wenham and Greenough binoculars converging tubes were used, largely for structural reasons, but the more modern binocular microscopes, as made on the Continent and in America, have parallel eyepieces. The reason for this is clear enough. One of the most elementary pieces of instruction to beginners with the microscope is to work with relaxed accommodation, partly because this is the most restful way to work, and partly (when a monocular instrument is used) to render the image seen by the unoccupied eye as vague and ill-defined as possible so that it may be the more easily disregarded.

Lately, however, two English manufacturers have attempted to reintroduce converging oculars in their binocular microscopes, the reason given being that, since the object is ten inches away, there is a tendency to imagine that you are looking at it direct, and that therefore you accommodate and converge your eyes. Furthermore, they say that it facilitates stopping to write notes, as you do not have to bring your eyes back from infinity. There is certainly increased difficulty in doing this after the age of 45 or thereabout, but microscopes are surely not made exclusively for workers over that age, and workers over this age may well have difficulty in accommodating to the ten inches laid down by the makers. The decision to change to converging oculars was apparently made at a conference of optical manufacturers, and one can only say that it is a pity they did not consult a competent physiologist before making the decision. For it is surely impossible simultaneously to converge your eyes and relax your accommodation without resultant eyestrain. The answer I have obtained from both manufacturers in response to inquiry has been that you do not in point of fact work with relaxed accommodation at all—an answer that seems to me at variance with the facts. All the experienced pathologists of my acquaintances work with relaxed accommodation as ascertained by careful testing. Where you are working (as with a microscope) with two focusing systems—the accommodation and the fine adjustment of the microscope—both focusing on an object at no clearly defined distance away, it is obvio best to keep one fixed and move only the other. the accommodation is powerless to do any but a fraction of the huge focusing that is necessary, it clearly the accommodation that must remain fixed, it can only do so comfortably at its limit—i.e., at relaxation.

Whatever may be the theory of the matter, practical aspect is decisive. The parallel-tube i ments are comfortable to work with all day—I done so myself for many years. But I have also of the converging type, and it only takes about f minutes' work with this to make my eyes ache and

It seems to me important to get this point settl and it would be a great help if a physiologist such Professor Hartridge would give us the benefit of opinion.

London, W.1. J. W. SHACKLE.

BAL

SIR,—

Ignoramuses like me
 Think the Editor might see
Ambiguities should be
 Made as plain as plain *can* be:
Judge today then my surprise
 That you did not put us wise
Thinking that we should surmise
 What BAL might epitomise.
As a favour, Sir, you might
 For those others in my plight
Let me that key-word indite—
 *B*ritish *A*nti-*L*ewisite.

ZETA.

Medicine and the Law

Dismissal of Suspected Typhoid Carrier

A CASE recently heard in the High Court at Dubl underlines the need for close adherence to regulations i securing exclusion of a suspected typhoid carrier fro work involving food-handling.

In May, 1945, a medical officer of health in received a letter from another medical officer of notifying him that a young woman believed to be at a hotel in the first M.O.H.'s area had cont typhoid in the previous July and had been empl as cook "on the Great Northern dining-car with an outbreak of typhoid was connected." On disch from hospital, the letter added, she had been cert as free from *Salmonella typhi*.

On receipt of this letter the M.O.H. visited the in question and confirmed that the woman had taken up an appointment there as cook. He expl to the manageress that it might be dangerous to e her as a food-handler. When interviewed the admitted that she had been employed in the dining- After further discussion with the manageress the M.O telephoned the hospital where her condition had b investigated and was told that investigation had poi to her as the cause of the outbreak. The M.O.H. a saw the manageress and said that he was afraid would have to stop this young woman from prepa and handling food. He did not tell her to sack the He told her that the hospital doctor had said that girl should not be employed as a food-handler, and felt that it was his duty to implement this b this doctor had said that she might be a preco carrier. He telephoned the Department of Health was told by an official that the girl should not, in opinion, be employed as a food-handler, but that decision would have to rest with the M.O.H. He wrote a letter to the manageress which included t words:

> "I am sorry to say that she is possibly a carrier of typhoid fever. She must not be employed you in any position connected with the preparation handling of food."

The manageress then dismissed the girl. The M. wrote down the patient's name in his register but

INCITEMENTS TO ACTION

Examples of the new murals at Orsett Lodge Hospital, Essex, described in THE LANCET, July 24, p. 167. The elderly and infirm patients are cheered and braced by these active scenes set in the times of their youth.

that the congress has set itself two tasks. The sections dealing with the environment, occupational hazards, and diseases of the worker will set out what the doctor's job in industry is; those on the training of industrial medical officers, on the organisation of industrial medical services, and on the integration of occupational health with national and community services will discuss how he may best get on with it. At the end of the congress proper Mr. H. E. Griffiths will give the Mackenzie industrial health lecture, at B.M.A. House, on the Surgeon in Industry. In the following week the delegates will scatter all over the country from Cumberland to South Wales, visiting research units and reablement centres, and watching our industrial health services—national and private—in action. All inquiries about the congress should be addressed to Miss G. B. Mawdesley, room 501, B.M.A. House, Tavistock Square, London, W.C.1.

PERMANENT COMMISSIONS IN THE R.A.F.

THE Royal Air Force is short of officers on the permanent staff of the medical and dental branches. Doctors and dentists who have left the R.A.F. on release and who are interested in making a career in the Service are accordingly invited to apply for permanent appointments in these branches. Applications should be addressed to the Air Ministry (M.A.1). Adastral House, Kingsway, London, W.C.2. All suitable officers now serving on short-service commissions are being considered for permanencies, and permanent commissions are being offered also to doctors and dentists who served during the war and who have now returned to civilian life.

HOME HELPS

THE London County Council has inherited the results of the work on the home-help service begun by the 28 metropolitan borough councils and the City Corporation. Mr. Reginald Stamp, chairman of the L.C.C. health committee, addressing the National Association of Home Help Organisers on July 17, said that in future the service will probably be planned for the nine London divisional areas coterminous with educational divisions. Home-help organisers will be appointed in each division, and will encourage properly qualified women to give help to the infirm or to those in need during times of sickness or other difficulty. The divisions will be split up into neighbourhood units, and just as the health visitor becomes familiar with families, so it is hoped will the organiser get to know the population intimately and prepare a setting for friendly understanding between helper and helped.

Payment of home helps is being arranged on lines which will take account not only of the need of help but of the ability of the citizen to pay. The organisers must create a public opinion which will enable the home help to do her work in the right atmosphere. She must not be made to feel subservient to the householder, and she must have the right attitude towards her service. The organisers, he suggested, should offer their home helps clubs and educational opportunities, not only to train them for their work, but to give them a broad interest in the affairs of human kind.

Miss Dorothy Elliott, chairman of the National Institute of Houseworkers, agreed that one of the chief tasks facing the institute was to build up a good domestic health service under the local authorities. This institute gives a diploma, and some of those holding it are already employed by local authorities as home helps.

A FIFTH FREEDOM

To the four freedoms of the Atlantic Charter, Ilford Borough Council have added a fifth—freedom from food and drink infection. To achieve this end they are undertaking a campaign which will include lectures and demonstrations to food-handling trades and their own provision of meals and catering services. Meanwhile a small but competent leaflet, illustrated with telling pictures, is being distributed to householders. It gives 23 items of good advice, preceded by a short homily on the principles which underlie methods of safeguarding food. Among other things, householders are advised to beware of transmitting infection from dirty hands and septic sores, to avoid touching the mouth or nose when handling food, to make sure that cooking utensils are clean, to keep the dustbin covered, to wash the hands after visiting the toilet, and to kill flies and bluebottles. Some useful advice for mothers follows, on the cleansing and sterilising of bottles and teats, and the care of the baby's food, especially broth.

LIFE WITH JUNIOR

THIS American "March of Time" film sets out to give some idea of the life and behaviour of 10-year-olds. The first part shows the routine and the adventures of a schoolboy throughout one day, with the repercussions of these adventures on the family life. The second part is devoted to problem children and the way in which the Child Study Association of America tries to deal with their difficulties.

It may be that the picture presented is typical of American middle-class patterns, but it is hardly typical of the same social strata in Great Britain. The juvenile court is reminiscent of the Brains Trust—children solving problems, with admiring parents sitting round and clapping their wisecracks. All the children, especially the girls, look rather overfed and are dressed and behave like Hollywood stars in miniature. The breaking of eggs into a hat in play, the bewildering variety and choice of delicious foods the American child refuses to eat, and the sight of the science room in the school for 10-year-olds with all its elaborate contraptions can only rouse envy in the British spectator.

year he joined the staff of the Welsh Board of Health as regional medical officer, an appointment which he held until his retirement in 1945.

During the late war Dr. Davies was seconded by the Welsh Board of Health to the Emergency Hospital Service as hospital officer for North Wales and deputy for the area. As such, he was responsible for organising the Emergency Services throughout the six counties of North Wales. "The strain of this work," a colleague writes, "which came at a time of his life when he was past his prime, must have contributed to the ill health which he suffered during his retirement. His kindly disposition, however, and his constant cheerfulness were strong enough to overcome his disabilities. His long experience as a general practitioner enabled him, when he joined the Board of Health, to carry out his official duties in an outstanding way. To doctors throughout Wales he was known as a kind friend, and cases referred to him were sure not only of sympathetic consideration but also of a first-class opinion."

Births, Marriages, and Deaths

BIRTHS

BLEAKLEY.—On Aug. 1, at Bangor, co. Down, the wife of Dr. John Bleakley—a son.

CLELAND.—On Aug. 3, at Irvine, the wife of Mr. Gavin Cleland, F.R.C.S.E.—a daughter.

COLE.—On July 30, at Dorking, the wife of Dr. William Cole—a son.

CONWAY.—On July 31, the wife of Dr. James Conway—a daughter.

COURTIN.—On July 22, at Rochester, Minnesota, the wife of Dr. R. F. Courtin—a son.

HARTLEY.—On Aug. 1, at Rye, the wife of Dr. J. L. Hartley—a daughter.

KINGDON.—On July 30, at Swanwick, the wife of Dr. John R. Kingdon—a daughter.

MORRISON.—On July 29, at Sheerness, the wife of Dr. J. N. Morrison—a daughter.

NOTT-BOWER.—On Aug. 3, at Cirencester, the wife of Squadron-Leader T. M. Nott-Bower, M.R.C.S.—a son.

PARSONS.—On Aug. 3, at Bexhill-on-Sea, the wife of Dr. A. C. D. Parsons—a daughter.

PAULLEY.—On Aug. 4, in London, the wife of Dr. J. W. Paulley—a daughter.

PRICE.—On Aug. 9, at Bath, the wife of Dr. A. E. Kingsley Price—a son.

QUINTON.—On July 30, at Ipswich, the wife of Dr. John Quinton—a daughter.

RICHARDS.—On Aug. 2, the wife of Dr. Donald Richards—a daughter.

ROBERTS.—On July 29, in London, the wife of Dr. A. T. M. Roberts—a daughter.

SHAW.—On July 31, at Braunton, the wife of Dr. F. O. J. Shaw—a daughter.

STEWART.—On July 29, at Preston, the wife of Major Walter Stewart, M.B.E., R.A.M.C.—a son.

VINE.—On Aug. 4, at Cambridge, the wife of Dr. Maudsley Vine—a son.

WATKINS.—On July 31, in London, the wife of Dr. P. F. A. Watkins—a daughter.

WRIGHT.—On Aug. 1, at Woking, the wife of Dr. R. B. Wright—a son.

MARRIAGES

CRAWFORD—KELSEY.—On July 29, at Shrewsbury, Frank John Hamill Crawford, M.D., to Louise Kelsey.

DALY—McVERRY.—On Aug. 4, at Rostrevor, co. Down, Dermot Alexius Daly, M.B., to Catherine Augustine McVerry.

WILSON—MARSDEN.—On July 17, Brian Douglas Raymond Wilson, M.B., to Violet Evelyn Marsden.

DEATHS

AITKEN.—On July 29, at Plymouth, Alexander Gardner Aitken, M.B. Glasg.

ALLARDICE.—On Aug. 2, at Newcastle-under-Lyme, Staffs, William Clachan Allardice, J.P., M.D. Glasg., F.R.C.S.E.

CUNNING.—On July 29, at Reigate, Joseph Cunning, M.B. Melb., F.R.C.S., F.R.A.C.S.

FERGUSSON.—On Aug. 2, at Goldsithney, Cornwall, James Herbert Fergusson, C.B.E., M.R.C.S., surgeon rear-admiral, R.N., aged 73.

MACKIE.—On Aug. 8, at Sandown, Kenneth William Mackie, M.R.C.S.

STONE.—On July 31, Robert Dudley Algeo Stone, L.R.C.P.I., aged 85.

WACE.—On Aug. 5, in London, Richard Henry Wace, M.B., aged 80 years.

Appointments

POND, D. A. R., M.D. Duke Univ., M.B. Camb., M.R.C.P., D.P.M.: asst. physician, department of applied electrophysiology, Institute of Psychiatry, Maudsley Hospital medical school.

• MILLAR, J. H. D., M.B.E., M.D. Edin., M.R.C.P.E.: physician, Scunthorpe and District War Memorial Hospital.

• Amended notice.

Notes and News

STREPTOMYCIN REGULATIONS

REGULATIONS have been made by the Minister of the Secretary of State for Scotland, and the Minister of and Local Government for Northern Ireland, after with the Medical Research Council, bringing within the scope of the Penicillin Act, 1947. The these regulations, which came into force on Aug. 1, is streptomycin and preparations containing streptomycin be supplied to the public only by or in accordance with directions of doctors, dentists, or veterinary surgeons, registered pharmacists on the prescription of doctors, denti or veterinary surgeons, and may be administered only by in accordance with, the directions of such qualified pra tioners. Though supplies of streptomycin have increase is still generally available only through the hospital serv The regulations anticipate the time when its use may extended. As with penicillin and preparations penicillin, pharmacists and authorised sellers of poisons be able normally to dispense a prescription for stre and preparations containing streptomycin only once and more than three months after the prescription was if, however, the prescription directs that it may be di on a specified number of occasions or at specified interval a specified period, it may be dispensed in accordance that direction.

VACANCIES IN PRACTICES

EXECUTIVE councils are reminded in a letter from Minister of Health that it is for them to inform the Med Practices Committee when a doctor notifies his intention withdraw from the medical list or when his name is remo from the list. At the same time they are to report to committee on the need to fill the vacancy; and it may assumed that the committee will normally accept the coun view. The council will also have to decide whether to advert any vacancy which the Medical Practices Committee agreed exists. In the case of withdrawals from the list which normally three months' notice is required), the Minis considers that vacancies should usually be advertised in medical and local press in ample time to allow a succes to be appointed before the outgoing doctor withdra Similarly, where an area is under-doctored, councils will to use their power to advertise. In the case of sudden de however, it is suggested that, to avoid delay, the vaca should be filled from any applications already recei subject to the views of the local medical committee. W a doctor dies suddenly, one of the following three tempo arrangements may be made, normally for not more two months: (1) the executive council may arrange other doctors in the locality to conduct the practice porarily; (2) the person acting on behalf of the estate sh be given the chance of appointing a locum tenens, pen the filling of the vacancy; or (3) failing this, the exe council may themselves, after consultation with the medical committee, appoint a locum tenens. A procedure may be followed if a vacancy occurs for some rea other than death and it cannot be immediately filled. Minister has decided that, after all, applications for consen employ an assistant should not, after they have been sidered by the council in consultation with the local med committee, be referred to the Medical Practices Commit unless: (a) the doctor making the application already empl an assistant; (b) the council proposes to refuse consent, (c) the Medical Practices Committee has notified the cou that the area already has sufficient doctors. Applications assistants for inclusion in the medical list will still nec be referred to the committee.

CONGRESS OF INDUSTRIAL MEDICINE

THE ninth International Congress of Industrial Medi will meet in London from Sept. 13 to 17 under the of the Commission Internationale Permanente pour Médecine du Travail. Lord Moran, P.R.C.P., will preside the opening of the congress, when Mr. G. A. Isaacs, Min of Labour and National Service, will give an address. Webb-Johnson, P.R.C.S., will be in the chair at the clo session, when the speaker will be Mr. G. R. Strauss, Mini of Supply. Both of these meetings will take place in Central Hall, Westminster. The scientific sessions will be nearby in the Caxton Hall and the Alliance Hall. The liminary programme,

THE AGRICULTURAL WORKER

G. F. Keatinge
M.A., M.D. Dubl., M.R.C.O.G., D.I.H.
CHIEF MEDICAL OFFICER TO THE BUTTERLEY CO. LTD
R. Littlewood

"One of the great lessons of history is that no nation can be stronger than its agriculture."—President Truman.

This country is short of food now and probably will be for some years. Increased food production is essential not only to save dollars but also to avert famine. Estimates of the additional labour force needed in agriculture this year vary from 20,000 to 80,000 regular workers, but no-one can say where even 20,000 workers are to be found. If they cannot be found, as seems probable, there are two alternatives—severe undernourishment within the next few years, or such an increase in the output per man-year as will enable the farming industry to reach the targets it has been set.

This paper is an attempt to investigate what contributions industrial and social medicine can make to assist British agriculture in its task. It analyses the causes, economic, political, and social, of the drift from the land which is the cause of today's shortage of agricultural workers, and, reviewing the conditions under which the farm worker earns his living, suggests ways by which his efficiency and status can be improved. Though we have felt for some time that such a study should be made we must acknowledge that the impetus came from the inspiring article on coalminers (Morris 1947) and the reflection that food is as important as coal to the national recovery.

The years 1840–70 were a golden age for British farming. About 1873 a period of depression began which, except for the artificial boom during and immediately after the first world war, lasted until 1939. Despite occasional good years farming continuously declined in importance and prosperity. Our farmers fought a losing battle against overseas farmers, who, cultivating fertile virgin land, had low costs of production and had, for allies, improved and new methods of transport, long periods of falling prices, a run of bad harvests in Great Britain, and, above all, our policy of free trade, which lasted from 1846 to 1931.

Owing to the rapid growth in population and the changes in the types of food demanded by workers with rising standards of living, our food requirements increased until by 1931 they were almost double what they were in 1861; and imports were essential because by 1870 there was as much land under cultivation as was possible under free trade (Astor and Rowntree 1938). Cheap food, moreover, was vital for the maintenance of the vast wage-earning community.

The battle against foreign competitors became a series of rearguard actions in which the British farmers fell back on products in which they enjoyed a naturally sheltered market. Since it was useless to compete with the American and antipodean producers of wheat and after the development of cold storage) meat, they concentrated on perishable foods, such as dairy produce, eggs, vegetables, and on the more expensive fresh meats. This involved a change from arable to grass farming. The acreage under permanent grass increased by over 0% between 1870 and 1938 (Addison 1939). Nearly ,500,000 acres, an area greater than the whole of Wales, was lost to the plough.

The more the land was laid down to grass, the less was the amount of employment offered by the industry. The conversion of ploughland to pasture reduced the labour employed by 7–9 men per 1000 acres (Ernle 1927), but this was often counterbalanced by the additional labour needed to look after the increased number of stock. The change, accompanied by a more efficient use of labour and by increasing mechanisation, was bound to reduce the number of agricultural workers. But the fall was an absolute decline, which was all the more surprising in view of the unprecedented growth of the population, which increased from 26,000,000 in 1871 to over 46,000,000 in 1937.

The Drift from the Land

The drift from the land was not confined to the nineteenth century or to this country. Movement away from the land has been, and still is, a feature of all developing countries, and such movement seems inevitable in a competitive world economy. Industrialisation, with its demand for labour, inevitably brings a flow of workers from agriculture to the factories of the towns. The decline in the rural population from 1881 to 1921 in some leading industrial countries was as follows (White and Shanahan 1932).

Rural population as percentage of total population

	1881	1891	1901	1911	1921
England and Wales..	32·1	28·0	23·0	21·9	20·7
Canada	..	68·3	62·6	54·6	50·5
U.S.A.	71·4	64·6	61·0	54·2	48·6

The industrial revolution began earlier in Great Britain than it did elsewhere and developed more rapidly. It speeded up the drift to the towns which the enclosures of the eighteenth century had already quickened. The Education Act of 1870 and the enfranchisement of the agricultural worker in 1884 gave additional impetus. Compulsory education and the possession of a vote meant that the countryman was at last brought into contact with the outside world and learned of the opportunities which it offered. When he lost his job or wanted to better himself he emigrated or, more often, migrated to the towns. The rural exodus varied from time to time and from place to place, being greatest in bad seasons and in districts adjoining industrial areas. It was most notable in the inter-war years. In 1921–24 the total number of workers, male and female, averaged 816,000, whereas in 1938 the number had declined by over 25% to 593,000 (Committee on Land Utilisation in Rural Areas 1942).

LOW WAGES AND LONG HOURS

One of the principal causes of this drift was the disparity between agricultural and industrial wages. There was a wide difference between the average wage of an agricultural worker and that of an unskilled labourer in industry, in spite of the fact that in agriculture even the general worker must be highly skilled. Throughout the nineteenth century the wages of town labourers were generally about half as high again as those of farm workers (Astor and Rowntree 1938). In the twentieth century the wages position can be seen from the following estimates made by Bowley (1937):

Average earnings of men and boys (shillings per week)

	1906	1924	1931	1935
Coalmining ..	31·5	53·0	45·2	44·5
Building	..	59·9	58·2	56·2
Textiles	22·9	51·0	48·0	49·2
Agriculture ..	18·3	31·5	35·0	35·7

Regulation of wages, introduced during the 1914–18 war, was made permanent by the Agricultural Wages (Regulation) Act, 1924, which empowered county committees to fix minimal wages. This brought some improvement in the level of wages, but in 1936, when unemployment insurance was first extended to agricultural workers, in some counties a land worker with a family, by obtaining an industrial job and qualifying for benefit, could receive more as an unemployed industrial worker than as an employed agricultural worker (Astor and Rowntree 1938). It is true that some agricultural workers had certain perquisites, such as low rent and

In the second part of the film this difference of cultural standards becomes even more apparent. The office of the Child Study Association, where parents apply for first-aid regarding their children's behaviour and upbringing, is impressively large and has about it the busy bustle of a railway station before Bank holiday. Mothers are interviewed by what are apparently social workers, and the children are not seen at all and there is no hint of psychiatric help for anyone. Rather curiously the only child shown in a clinical set-up is doing a Rorschach test.

From the comfortable bourgeois families to the rapid and easy successes in treatment, there is little that a British child-guidance worker will recognise as typical of her work. In fact, as a presentation of child guidance the film is so misleading that it would be a pity if it were widely shown in this country. It would be helpful to know how it is viewed by serious child-guidance workers in America.

TELEPHONE RELAY

Ilford Medical Society has arranged for a telephone operator to take urgent calls from local patients whose doctor is off duty, and to put them in touch with another doctor. By this arrangement, forty-four of the fifty doctors in the area are free on Thursday afternoons and evenings and all day on Sundays. Each works at these times one week in twelve. The operator's number is Valentine 1380.

At Birmingham the executive council is reported to have considered a proposal for a telephone system whereby members of the public unable to locate their local practitioner would dial a special number through which they would be connected with another doctor. This system, it has been suggested, should be integrated with that to be operated for the ambulance service, and possibly also with that of the bed bureau.

University of Oxford

On July 31 the following degrees were conferred:

D.M.—G. I. M. Swyer.
M.Ch.—G. O. Jolly.*
B.M.—R. A. Bruce, J. P. Horder, W. G. H. Leslie, M. C. Manifold, David Razzak, C. G. A. Thomas, H. W. James, A. W. Lindsay, M. G. M. Venables, W. H. Taylor, D. P. Winstanley, N. S. C. Gent, F. D. Kelsey, J. R. Sudbury, F. J. C. Roe, Leon Bagratuni, G. E. S. Jones, D. R. Richard, Katharine M. S. Ainley Walker, Barbara E. Porritt, D. F. Magee,* Harold Ellis,* J. E. Cotes,* P. D. Wall, Peter Harrison-Hall,* M. A. Peyman,* John Swithinbank,* B. L. Day,* J. N. Micklem.*

* In absentia.

University of London

Dr. E. P. Sharpey-Schafer, whose appointment to the chair of medicine at St. Thomas's Hospital medical school we announced last week, has been for the last twelve years on the staff of the Postgraduate Medical School of London, where he is now physician and senior lecturer in medicine.

Dr. Sharpey-Schafer, who qualified in 1933, received his medical education at the University of Cambridge and at University College Hospital, where he was awarded the Fellowes gold and silver medals for clinical medicine. Two years later he took the M.R.C.P. After holding house appointments at his own hospital he became R.M.O. at the National Hospital for Diseases of the Heart in London. He has published papers on endocrinology, dealing mainly with thyroid disturbances, and in recent years his research interest has been mainly on circulatory dynamics. He has also published many papers on the circulatory effects of hæmorrhage, the circulation in anæmia, and (jointly) on the pharmacological action of digitalis and other substances in heart-failure.

Royal College of Surgeons of England

Faculty of Anæsthetists.—On July 8 the council of the college admitted the members of the board of the faculty to its new established fellowship (F.F.A. R.C.S.).

Edinburgh Post-Graduate Board for Medicine

On Friday, Aug. 20, at 3.30 P.M., in the anatomy theatre of the university, Prof. E. B. Verney, F.R.S., will give a lecture on Urine Secretion.

Patients' Pictures

A collection of pictures by patients of Netherne Hospital, which have been used as an aid to the understanding of emotional disturbances and are of diagnostic and therapeutic value, will be on view at 1, Grosvenor Crescent, London, S.W.1, from Aug. 16 to 21. The exhibition will be open daily from 10.30 A.M. to 4.30 P.M. and on Saturdays from 10.30 A.M. to noon. Visitors to the exhibition will also be able to see some aspects of the work of the British Red Cross Society picture library and the St. John and Red Cross hospital library.

London College of Osteopathy

A nine-month course, open to registered medical pract tioners, on the theory and practice of osteopathy will begi at the college on Oct. 3. Further information may be ha from the secretary, 24, Dorset Square, London, N.W.1.

British Association of Physical Medicine

A course of lectures suitable for candidates preparing f part II of the diploma in physical medicine will be held o Tuesdays and Thursdays from Sept. 2 to Oct. 7, at 5 P.M. Further details can be had from the honorary secretary of th association, 45, Lincoln's Inn Fields, London, W.C.2.

Royal Institute of Public Health and Hygiene

Dr. Paul Banzet, surgeon to the Hôpital Broussais, Pari will deliver the Bengué lecture for 1948 on Wednesda Sept. 22, at 3 P.M., at the institute, 28, Portland Plac London, W.1. He will speak on the Surgical Treatment o Gastric Ulcers.

Alvarenga Prize

The College of Physicians of Philadelphia have awarde this prize to Prof. Melvin H. Knisely, of the University o Chicago, for his work on sludged blood (see *Lancet*, 194 i, 26).

Foreign Medical Scholarships

The British Council have been asked by 9 foreign countri to recommend candidates for some 40 scholarhips. Th scholarships are given to reciprocate scholarships or othe assistance given by the council and provide for a period of study abroad which varies from four months to two years. The following awards have been made:

The Belgian government a scholarship in tropical medicine to Dr. H. F. Lyon (Edinburgh) and another in dermatology to Dr. R. P. Warin (Leeds); the government of Sweden and the Swedish Institute a scholarship in surgery to Dr. C. Dafoe (Ontario), and in surgery to Dr. J. Scott Baker; the Netherlands government a scholarship in ophthalmology to Miss L. Hodgson (Leeds).

Conference on Infertility

The Family Planning Association are holding their annual conference on this subject at Exeter on Sept. 25 and 26. The speakers will include Mr. D. Young (Congenital Absence of the Vas); Mr. Albert Sharman (Uterotubal Insufflation); Miss Josephine Barnes (Hysterosalpingography in Water-soluble Radio-opaque Media); Dr. M. Hadley Jackson and Dr. H. A. Davidson (Vitamin-E Therapy for Subfertility in the Male); Dr. Mary Barton (Value of the Sims Test in the Diagnosis of Male Infertility); Dr. E. Friedman (Testicular Biopsies); Miss M. Moore White (Testosterone Implants); Dr. R. G. Harrison (Blood-supply of the Testis and its Relation to Sterility); Dr. G. I. M. Swyer (Assessment of Infertility Data). Further information may be had from the secretary of the association, 69, Eccleston Square, London S.W.1.

National Association for the Prevention of Tuberculosis

The jubilee of the association will be celebrated next year, and one of the principal functions will be the Commonwealth and Empire Health and Tuberculosis Conference to be held at the Central Hall, Westminster, London, S.W.1, on July 5, 6, and 7, 1949. The programme will include the following subjects: tuberculosis as a world problem; modern treatment and its results, including P.A.S. and streptomycin; mass X-ray methods; regional county tuberculosis schemes, organisation of comprehensive tuberculosis schemes in British colonies; tuberculosis among nurses and students; eradication of bovine tuberculosis.

A prize of 100 guineas will be awarded for an essay on the control of tuberculosis in a British colony.

The competition is open to doctors of either sex in the British Colonial Medical Service of not more than ten years', nor less than five years' medical standing, of which at least three have been spent overseas. Essays should reach Dr. Harley Williams, N.A.P.T., Tavistock House North, London, W.C.1, not later than March 1, 1949.

Last year the Institution of Mining Engineers and the Institution of Mining and Metallurgy held a conference on Silicosis, Pneumoconiosis, and Dust Suppression in Mines (*Lancet*, 1947, i, 641). The proceedings have been published and are obtainable, price £1, from these institutions at Salisbury House, Finsbury Circus, London, E.C.2.

rather below the average in the list of recorded occupations. The situation is different, however, in the case of women agricultural workers, who, with domestic servants, have the highest rate of illness for any recorded occupational group.

The high labour turnover in the Women's Land Army, much of which is due to sickness and accident, is another indication of the high incidence of sickness among women engaged in agricultural occupations. Exact figures are not available, but a special analysis made in January, 1945, showed the resignation-rate from all causes to be 3·22%, of which 1·22% was represented by sickness and accident (Ministry of Agriculture and Fisheries 1948).

Forestry work is more exacting than the average work performed by a woman on a farm, but it is not without relevance that an investigation into the health of women forestry workers showed their sickness-rate to be high, averaging a loss of twenty days a year by each worker. Many of the women engaged in this work had also lost weight. Though the figures were too small to be of statistical value, 40% of all releases from the Women's Timber Corps in the administrative divisions visited were on medical grounds (Swanston 1944).

Though the mortality-rate for the whole male population in rural areas in England and Wales was 81, that of agricultural occupations was even more satisfactory, being only 73 (Registrar-General 1931). Despite the high level of sickness among single women employed in agriculture, they show a favourable mortality-rate of 87, compared with 100 for all single women living in rural districts.

Nevertheless the mortality among farmers was significantly above the average for septicæmia, suicide, and diabetes, and probably for blood diseases and appendicitis. The mortality among farmers' wives was significantly above the average of that among all married women for maternal causes and exophthalmic goitre, and probably for influenza and non-respiratory tuberculosis. The agricultural labourers had a mortality probably indicating a significant excess for hernia, and an excess not statistically significant for cancer of the skin and non-respiratory tuberculosis. The wives of agricultural labourers showed a probably significant excess for pernicious anæmia and maternal diseases.

The significant excess noted in the farmer for septicæmia and appendicitis, in his wife for maternal causes, and in the agricultural labourer for hernia may well be explained by the difficulty in obtaining prompt and adequate treatment under proper conditions by those living in isolated areas. It is less easy to explain the significantly high incidence of suicide in the farmer, which had also been noted in 1921–23 (Registrar-General 1931). It may be due to solitude and the lack of social contacts in certain cases; on the other hand, the fact that the main motive for attempted suicide was a material one in 87 out of 100 cases investigated by Von Andics (1947) suggests that suicide in the farmer may reasonably be attributed to the anxieties with which he had to contend in the critical years from 1921 onwards. Perhaps the significant excess of exophthalmic goitre in the farmer's wife may bear some relation to the same cause. The excess of non-respiratory tuberculosis noted in the agricultural labourer and the farmer's wife can hardly be dissociated from the ingestion of infected raw milk. Among the conditions showing an excess mortality in farmers and agricultural labourers, however, only cancer of the skin can be held to have a possible occupational basis.

Toxic Hazard.—Despite the favourable situation of the agricultural worker as regards both incapacitating sickness and mortality, the occupational hazards to which he is exposed are not few, and among them toxicological risks have become more frequent owing to the application of scientific and engineering methods to farm work. Thus the use of mercurial compounds, such as tolyl mercuric acetate in treating seeds (Goldblatt 1945) and methyl bromide as a fumigant to destroy insects likely to damage picked fruit, have already caused serious effects on workers (Johnstone 1945). Among other dangerous insecticides are certain of the fluorine compounds which also serve as artificial fertilisers (Hunter 1939), and dinitro orthocresyl, which as a spray has been responsible for the deaths of several workmen. The internal combustion engine has brought with it the risk of exposure to oils capable of causing dermatitis and keratotic changes in the skin (Twort and Lyth 1933). Other toxic hazards are the use of arsenical compounds as sheep dip (Paufique and Bonamour 1946) and the use of tar derivatives in the preservation of timber (Henry 1946).

Diseases of Animals.—The fact that farmers and agricultural workers show a high incidence of certain diseases communicable from animals to man, such as abortus fever, glanders, and anthrax, is comparatively well known; yet the diagnosis is often overlooked, at any rate in the early stages, and this may have serious consequences. In the case of anthrax, for example, though the causal organism is sensitive to penicillin (Murphy et al. 1944), delay in beginning its administration greatly reduces the chances of recovery. Though man is relatively immune to infection with *Erysipelothrix rhusiopathiæ*, the causal organism of swine erysipelas (Barber 1948), it is probable that a good many cases pass unrecognised and that the incidence is greater than is generally supposed (Glover 1948). Aphthous fever occasionally occurs in man (Dlugosz 1943), and ringworm can be transmitted from various animals. Few farms are free from rats, and the farm worker is bound to come in contact with them directly or indirectly. In the former case rat-bite fever may result, and in the latter Weil's disease may be contracted, for it has been shown that contamination of rivers and water-ways is a common cause of this condition (Robertson 1946). There is also reason to believe that the virus causing sway-back in sheep may give rise to disseminated sclerosis in man (Campbell et al. 1947).

Fungi.—Among other fungi especially likely to affect workers on the land is aspergillus, which on inhalation causes "farmer's lung" (Fawcitt 1936).

Accidents.—No reliable statistics are available about accidents in farm work. Though there is reason to think that the accident-rate is not high, some farm accidents can cause very severe injuries and may be followed by tetanus.

Allergy.—Though plants are more liable to cause allergic conditions in gardeners, the agricultural labourer is not immune and may also be affected by animal hairs which can cause a severe reaction in a sensitive person (Britton 1947).

Occupational Disease.—What seems to be a true occupational disease has been described by Bellesini (1947), who states that the hands of milkers show arthritic changes in the terminal interphalangeal joints of the index and middle fingers. He attributes this condition to faulty technique in milking and advocates proper instruction.

Though incomplete, this is a formidable list of hazards; but, when in addition to them the social conditions are borne in mind, it is indeed surprising that the health of the agricultural worker is so good.

The Position Today

The outbreak of the 1939–45 war involved the agricultural industry in a "ploughing up" campaign to lessen the nation's dependence on food imports and to save shipping space. In 1939–44 the arable area was free produce from the farm: but, even when allowance is made for these, the disparity remained great.

The working week in agriculture also compared unfavourably with the industrial working week, which was progressively shortened by the various Factory Acts and the efforts of strong trade unions. By the nineteen-thirties the eight-hour day had been widely secured, but in agriculture the standard hours varied from 48 to 60 a week. In some districts they were considerably more, the West Riding, for example, having customary hours of 67½ a week in summer and 63 a week in winter (Addison 1939). A seven-day week was the rule rather than the exception, and even Christmas Day and Good Friday were holidays with pay only in some counties, in spite of all the efforts of the National Union of Agricultural Workers.

The farm worker had little prospect of rising in the world. With wages barely sufficient to live on it was almost impossible to accumulate capital to farm on his own account, nor could he often hope to rise to the position of foreman or manager, since few farms were large enough or prosperous enough to support such posts.

SOCIAL CONDITIONS

Housing in country areas was generally bad, and many cottages were not even worth the 2*s.* rent charged in some counties. Though some improvements were made during the inter-war years, many rural houses in 1939 had no electricity, no gas, and no water. Surveys made in the 'thirties emphasised repeatedly the shocking housing conditions. The Northamptonshire survey condemned no fewer than 5000 cottages out of 25,400 examined, and in the New Forest out of 700 cottages examined 255 were entirely unfit for human habitation and 208 others needed reconditioning (Addison 1939). A survey carried out four years ago speaks of "conditions dangerous to health and offensive to decency," "water contaminated by sewage and cattle pollution," and "pail closets shared by two or more families, their contents shot onto the nearest rubbish heap or carried through the house for a fortnightly street collection" (National Federation of Women's Institutes 1944). Overcrowding was common, 41,928 houses in rural areas being scheduled as overcrowded under the Overcrowding Act, 1935.

Urban houses were by no means always ideal, but at their worst they usually had artificial lighting and piped water, all too often absent in the country. And even the slum-dweller, overcrowded and insanitary though his home might be, lived in a community and could enjoy the amenities, amusements, and social services that increasingly became the concomitants of town life. The rural community in this respect was only too obviously at a disadvantage.

> It "received unequal treatment in respect of certain important public services, partly because it has been ill-organised for pressing its claims, partly because it has been unable to pay as large a share of the costs as urban communities can, and partly for the obvious reason that such services are more expensive to provide where the population is scattered" (Astor and Rowntree 1938).

Education.—From the educational standpoint rural areas compared unfavourably with the towns. Some schools were closed down owing to the decline in population, and children had to walk miles to school. Others had buildings and sanitation far below modern standards —in 1944 half had nothing but earth-and-bucket closets and often not enough of them (National Federation of Women's Institutes 1944). Rural children were handicapped when competing for scholarships for higher education because the better teachers tended to prefer the towns, where conditions were more congenial (Astor and Rowntree 1938). And our system of education "devised and inspected by city folk intent on producing not peasants but clerks" did not meet needs and made no attempt to foster "an intell and loving interest in country life" (Trevelyan 19,

Health services were also denied to the country-d to some extent. Though the health surveys of 1945 that before the war the agricultural areas were at as well served as the industrial areas on the ba number of inhabitants per hospital bed, the ge hospitals, being in the larger towns, were too far for the countryman. Small villages had no docto baby-welfare clinic, and no maternity home. The di nurse often served two or more parishes, and the mi was not infrequently "the woman from down the l

General Conditions.—The agricultural worker, b educated than his forebears and no longer absorb his own surroundings, suffered from a feeling of isol which, paradoxically, the spread of road transport increased. His stake in the agricultural community vanished with the enclosure movement of the nineteenth century, and he saw before him only ' unending vista of a gradual process of physical exhau in another's service" without any of the compensa that sweetened the existence of the town worker (E 1927). He was the helot of the nation and escaped his slavery whenever he could. Farmers, often weig down with mortgages, could do little to improve co tions for their workers. Higher wages, shorter ho repairs to cottages, all meant increased costs w could not be supported by the low prices they recei for their produce. The nation as a whole seemed indiffe to their plight. A town-bred electorate saw in the de of agriculture the downfall of an aristocratic syst and the natural outcome of the policy of laisser fa and "statesmen regarded the fate of agriculture w all the more indifference because it involved no sc problem of unemployment" (Trevelyan 1944).

AN AGEING LABOUR FORCE

Between the wars agriculture, in common with other depressed industries, was faced with the prob of an ageing labour force.

> "The greatest cause of the drift from the village that been going on for a long time past," declared a former Mini of Agriculture in 1939, "is the feeling of the young men women that they may have a better chance somewhere Where there were 100 employed who were under 21 in there were only 73 in 1931, and the figure has become sm since then" (Addison 1939).

The number of regular workers under 21 decrea by some 75,000 (nearly 44%) between 1921–24 and (Committee on Land Utilisation in Rural Areas 19 Agriculture had always relied for its new entrants family recruitment, but "just as in coalmining, children of farm workers when leaving school chose ot occupations—any work other than farming where wa were so bad and prospects so poor" (Macpherson 1947

Fertility and Health

In view of all these conditions it is surprising to that the traditional fertility of the farm labourer wa little affected. The declining birth-rate common every social and occupational class in the last h century showed the least decrease in the agricult districts (Martin 1937). Innes (1941) has calcula that the decrease in the birth-rate in 1921–31, a per of great agricultural depression, was 21% for agricultu labourers compared with 43% for semi-skilled text workers and 50% for semi-skilled miners.

SICKNESS AND MORTALITY

The Department of Health for Scotland (1937) sho that the incidence of sickness was not unduly h among male agricultural workers, who in 1935, w 14 cases per 1000 men employed, occupied a positi and though school-children and holiday workers under the "Lend a Hand on the Land" schemes give some assistance they are only obtainable in the summer months. The realist policy is, therefore, not "more men," for in the absence of some form of conscription they are unobtainable, but "better men."

BIGGER UNITS

How, then, is the agricultural industry to obtain its better men? Both the Government and the industry are doing much to attain this objective, but in our opinion their improvements do not go far enough.

Omitting all holdings of less than 5 acres, 74% of all farms in Great Britain do not exceed 100 acres, and only 4% are over 300 acres. Agriculture has seen few of the amalgamations and concentrations that have characterised all our other large industries in the last century. The unit of British farming is still the small farm.

There have been good reasons for this in the past. Returns from farming have been too low to attract or to provide the capital which large-scale farming requires; it is physically impossible to extend some farms; and the present system of land tenure favours small farms because there are more prospective small tenants than large ones (Astor and Rowntree 1938). There has been opposition on both sentimental and political grounds. Many people still believe that the yeoman is the backbone of England, and proposals for large-scale farming have usually been condemned as "socialistic," as was the case with the Large-Scale Farming Corporation embodied in the Land Utilisation Bill, 1930 (Addison 1939).

Nevertheless, as an economic proposition there is no question of the advantages of the large farm both for the employment of capital and the remuneration of labour. The small farm is an anachronism which the nation cannot afford to perpetuate in a period of world-wide shortage of food. Nothing so sweeping as collectivisation or nationalisation is advocated, but we suggest that a gradual aggregation of farms into bigger units will benefit both the farming industry and the nation. It is beyond our scope to suggest how this should be done, but it is difficult to imagine its being carried out without some form of compulsion.

Such aggregations of units would give farmers the advantages of easier marketing, bulk-buying, lower overheads, &c. They would facilitate the provision of scientific and technical advice, efficient direction, and up-to-date business methods, such as costing, which is particularly lacking on many present-day farms. They would ensure that the best use was made of machinery and expensive equipment, for, now that the tractor has taken the place of the horse as the unit of farm power, " 200–300 acres of arable land, according to soil, is a minimum for the most efficient utilisation of the implements and machines employed today in the various operations of cultivation and harvesting (Astor and Rowntree 1938). The present trend of scientific and mechanical invention, too, will increasingly favour larger units of production.

Larger farms would do much to raise the status and prestige of the industry. The farm worker would have more opportunity to learn modern methods, and there would be more opportunities of promotion to managerial and supervisory jobs. Agriculture would become even more mechanised and highly skilled, and would require greater knowledge about breeding, nutrition, chemistry, &c. As its "professional" status grew, it would attract men and women who were interested in the land as a way of life that was intellectually as well as spiritually rewarding.

Above all, larger units would make it possible to maintain small communities in which farm workers could lead a social life and continue the team spirit which large-scale farming would both demand and develop. Such communities would not only facilitate the extension of essential services and amenities but also would provide the corporate life which gregarious man needs if he is to give of his best.

MEDICAL SERVICES

Supervision of the worker's health at his place of work has now become a commonplace in many industries, and medical services are firmly established in undertakings under the control of large organisations, such as the big combines and the Ministry of Supply. It has already been shown that the hazards of the agricultural worker are not small, but specialised medical supervision of the occupational health of the agricultural worker has not been practicable in the past owing to the small size of the British farm. If, as we believe is possible, larger farming units can be organised, the principles of industrial medicine can be put into practice.

The new entrant to the agricultural industry can be properly placed in work within his powers only if all workers are medically examined. It is our experience that it is even possible to place disabled persons with certain kinds of defect in suitable jobs despite the arduous nature of much farm work.

Medical examination is of special importance for young persons, who will be spared the disappointment and waste of time entailed in taking up work for which they are not suited. Medical examination of the young person in a factory within fourteen days of starting work is obligatory under the Factories Act, and what is required in a factory is at least as necessary for the farm. Similar precautions are especially necessary in the case of women seeking employment on the farm, and the high incidence of sickness to which attention has been drawn could probably be reduced greatly by proper placement of women in suitable occupations.

The risk of ill effects on the health of man or animals if grain, fruit, or vegetables treated with toxic materials are eaten by them is not so great as might have been anticipated. Thus Spencer et al. (1948) show that, however toxic dinitro orthocresyl may be to the operators using it as a spray, the crops treated with it are harmless by the time they are used as food. Nevertheless, medical advice should be available on the hazards to the consumer in the use of toxic substances for this purpose.

First-aid material and equipment, though almost unheard of on the farm, are as necessary as elsewhere, and the training of workers in their proper use is easy to arrange where there is a medical service. Moreover, if the farm worker of the future is to live a community life, not only will his social conditions and those of his family improve but also his health should be better, provided that the communities in which he lives are not too large. In fact he ought to have the best of both worlds, enjoying, on the one hand, the open-air life of the countryman and the valuable perquisites which provide him with a diet above the average, and, on the other hand, the improved housing, sanitation, water-supply, and general services of the town.

increased by over 6,000,000 acres, and the number of workers by 172,000—an increase of 21% (Agricultural Statistics 1947). Owing to the demands of the Services the number of regular male workers fell by 20,000, and the increased labour requirements were met by an increase of well over 100% in female workers (mainly in the Women's Land Army), by the employment of prisoners-of-war, and by an increase in the amount of casual labour (Agricultural Statistics 1947).

The increase in the volume of output over 1939 has been estimated at about 30%, and the increase per man at the highest point was about 10–15% (Ashby 1947). This was largely made possible by increased mechanisation. At the end of the war British agriculture was more mechanised than any other agricultural system in the world (Parker 1947).

To meet the rise in the cost of living and to keep workers on the land wages were periodically increased. When the war ended, a national minimum wage of 70*s*. for a 48-hour week was in force for the male worker.

MAN-POWER

The agricultural industry has been given a target of £100,000,000 worth of extra food by 1951–52. On present prices this represents an increase in production of 20%.

The Economic Survey (1948) assesses labour requirements for this programme as 1,110,000 workers in 1948, rising to 1,170,000 in 1951. Allowing for the recruitment of Poles and E.V.W.'s and for the retention of ex-prisoners under civilian contract, some 10,000 British workers will be needed to achieve this year's total. But the figure is likely to be larger than this, since there may be some loss of regular women workers and, owing to the raising of the school-leaving age, there will not be the usual intake of 15,000 juveniles (Economic Survey 1948).

To prevent withdrawals from the industry the call-up of farm workers for military service has been cancelled for the next two years, and the duration of the Essential Works Order has been extended. The Government's main stimuli for recruitment are propaganda, the improvement of conditions of service in the Women's Land Army, and priority for new houses and hostels for agricultural workers. There is also a system of direction under which directees can choose agriculture from a long list of other undermanned essential industries.

Today's battle for output is partly the problem of *obtaining man-power and getting it into the right places* (Economic Survey 1947). The over-all labour force falls substantially short of what is needed to reach the national objectives; and, in the absence of a system of complete direction such as obtained in war-time, the movement from non-essential to essential industries can be influenced only indirectly. In effect, labour still has freedom of choice, and those undermanned industries which are the most congenial or offer the best opportunities will gain most recruits.

CONDITIONS

Farmers, assured of a schedule of guaranteed prices that gives them the greatest opportunity for good farming that they have ever had (Street 1947), can at last afford to pay decent wages. With a minimum wage of 90*s*. the farm worker is as well off financially as most of his counterparts in the towns. But, though in these days of rationing his perquisites (low rent, free milk, potatoes, &c.) increase his real wages substantially, farm wages are still not high enough to override the attractions of urban industries or to compensate for the lack of amenities in rural England.

The working week in agriculture is much longer than in other industries. Weekend work is necessary for milking and stock-feeding, and overtime is inevitable
during the harvests. The farm worker avera
more than his minimal 48 hours; and, thou
paid for any overtime, he has little leisure
with the factory worker, who often has a five

Future Needs

BETTER MEN

It is not surprising, then, that agricultural emplo
is generally unattractive to urban workers. A m
of its unattractiveness can be seen in the failure
Government's agricultural training scheme for ex-S
men, and in the exodus from the Women's Land
when the war ended. Not until the industry ca
amenities and conditions comparable with those e
by workers in other industries will it obtain the n
of regular male workers it needs. Nor can female

and though school-children and holiday workers under the "Lend a Hand on the Land" schemes give some assistance they are only obtainable in the summer months. The realist policy is, therefore, not "more men," for in the absence of some form of conscription they are unobtainable, but "better men."

BIGGER UNITS

How, then, is the agricultural industry to obtain its better men? Both the Government and the industry are doing much to attain this objective, but in our opinion their improvements do not go far enough.

Omitting all holdings of less than 5 acres, 74% of all farms in Great Britain do not exceed 100 acres, and only 4% are over 300 acres. Agriculture has seen few of the amalgamations and concentrations that have characterised all our other large industries in the last century. The unit of British farming is still the small farm.

There have been good reasons for this in the past. Returns from farming have been too low to attract or to provide the capital which large-scale farming requires; it is physically impossible to extend some farms; and the present system of land tenure favours small farms because there are more prospective small tenants than large ones (Astor and Rowntree 1938). There has been opposition on both sentimental and political grounds. Many people still believe that the yeoman is the backbone of England, and proposals for large-scale farming have usually been condemned as "socialistic," as was the case with the Large-Scale Farming Corporation embodied in the Land Utilisation Bill, 1930 (Addison 1939).

Nevertheless, as an economic proposition there is no question of the advantages of the large farm both for the employment of capital and the remuneration of labour. The small farm is an anachronism which the nation cannot afford to perpetuate in a period of world-wide shortage of food. Nothing so sweeping as collectivisation or nationalisation is advocated, but we suggest that a gradual aggregation of farms into bigger units will benefit both the farming industry and the nation. It is beyond our scope to suggest how this should be done, but it is difficult to imagine its being carried out without some form of compulsion.

Such aggregations of units would give farmers the advantages of easier marketing, bulk-buying, lower overheads, &c. They would facilitate the provision of scientific and technical advice, efficient direction, and up-to-date business methods, such as costing, which is particularly lacking on many present-day farms. They would ensure that the best use was made of machinery and expensive equipment, for, now that the tractor has taken the place of the horse as the unit of farm power, "200–300 acres of arable land, according to soil, is a minimum for the most efficient utilisation of the implements and machines employed today in the various operations of cultivation and harvesting (Astor and Rowntree 1938). The present trend of scientific and mechanical invention, too, will increasingly favour larger units of production.

Larger farms would do much to raise the status and prestige of the industry. The farm worker would have more opportunity to learn modern methods, and there would be more opportunities of promotion to managerial and supervisory jobs. Agriculture would become even more mechanised and highly skilled, and would require greater knowledge about breeding, nutrition, chemistry, &c. As its "professional" status grew, it would attract men and women who were interested in the land as a way of life that was intellectually as well as spiritually rewarding.

Above all, larger units would make it possible to maintain small communities in which farm workers could lead a social life and continue the team spirit which large-scale farming would both demand and develop. Such communities would not only facilitate the extension of essential services and amenities but also would provide the corporate life which gregarious man needs if he is to give of his best.

MEDICAL SERVICES

Supervision of the worker's health at his place of work has now become a commonplace in many industries, and medical services are firmly established in undertakings under the control of large organisations, such as the big combines and the Ministry of Supply. It has already been shown that the hazards of the agricultural worker are not small, but specialised medical supervision of the occupational health of the agricultural worker has not been practicable in the past owing to the small size of the British farm. If, as we believe is possible, larger farming units can be organised, the principles of industrial medicine can be put into practice.

The new entrant to the agricultural industry can be properly placed in work within his powers only if all workers are medically examined. It is our experience that it is even possible to place disabled persons with certain kinds of defect in suitable jobs despite the arduous nature of much farm work.

Medical examination is of special importance for young persons, who will be spared the disappointment and waste of time entailed in taking up work for which they are not suited. Medical examination of the young person in a factory within fourteen days of starting work is obligatory under the Factories Act, and what is required in a factory is at least as necessary for the farm. Similar precautions are especially necessary in the case of women seeking employment on the farm, and the high incidence of sickness to which attention has been drawn could probably be reduced greatly by proper placement of women in suitable occupations.

The risk of ill effects on the health of man or animals if grain, fruit, or vegetables treated with toxic materials are eaten by them is not so great as might have been anticipated. Thus Spencer et al. (1948) show that, however toxic dinitro orthocresyl may be to the operators using it as a spray, the crops treated with it are harmless by the time they are used as food. Nevertheless, medical advice should be available on the hazards to the consumer in the use of toxic substances for this purpose.

First-aid material and equipment, though almost unheard of on the farm, are as necessary as elsewhere, and the training of workers in their proper use is easy to arrange where there is a medical service. Moreover, if the farm worker of the future is to live a community life, not only will his social conditions and those of his family improve but also his health should be better, provided that the communities in which he lives are not too large. In fact he ought to have the best of both worlds, enjoying, on the one hand, the open-air life of the countryman and the valuable perquisites which provide him with a diet above the average, and, on the other hand, the improved housing, sanitation, water-supply, and general services of the town.

MENGO ENCEPHALOMYELITIS

A HITHERTO UNKNOWN VIRUS AFFECTING MAN

*From the Yellow Fever Research Institute, Entebbe, Uganda**

MENGO encephalomyelitis virus was originally isolated from a paralysed rhesus monkey (UR 22) which had been captive in the outside monkey runs in the compound of the Yellow Fever Research Institute in Entebbe (Dick et al.). This monkey had not been subjected to any experimental procedures. Subsequently a strain of Mengo encephalomyelitis virus was isolated from mosquitoes of the *Tæniorhynchus* (*Coquillettidia*) *fuscopennatus* Theobald species captured in the monkey runs in the same compound. Strains of the virus were also isolated from another lot of tæniorhynchus (consisting mainly of *T.* (*C.*) *fuscopennatus* Theo.), from a mongoose (ichneumia sp.), and, about a year after the first isolation, from another unused captive rhesus monkey which was febrile but showed no evidence of paralysis. The isolation of Mengo encephalomyelitis virus, its immunological specificity, its pathogenic and physical properties, and the histological lesions which it produces will be described elsewhere. A case of human infection with Mengo encephalomyelitis virus, the isolation of the virus from the patient, and the results of preliminary studies on human immunity to this virus are reported here.

The infection took place in one of us (G. W. A. D.), who was living in the compound where Mengo encephalomyelitis virus was isolated from the rhesus monkeys, the mongoose, and the batch of *T.* (*C.*) *fuscopennatus* mosquitoes, and who had been handling the virus more extensively than had the rest of us. No other infections with this virus have occurred among the European, Goan, or African staff members who have taken part in experiments with the virus or who have lived in the compound.

CLINICAL FEATURES

Incubation Period.—No definite information on incubation period of the infection in man is availal but, if the infection was naturally acquired, and if seems most probable, it took place at Entebbe, maximal incubation period was probably nine d because before that the patient had been absent fr Entebbe for eleven days. If the infection was contra in the laboratory the incubation period was proba five to eight days, estimated from the dates on wh the patient was handling Mengo encephalomyelitis vi before the beginning of his illness.

Onset.—The patient had had an attack of bronchitis, fr which he had practically recovered. On Nov. 22, 1946, felt slightly "out of sorts" physically, but towards even he became mentally very alert. He experienced sl shivering at night. Next day he awoke with a very sev headache, of a "bursting" type, which was aggravated coughing or by quick movements. Later the heada became so violent that he hesitated to cough or to str in any way. He had no fever and proceeded on saf driving 240 miles. On the journey he took repeated doses of aspirin but these did not relieve the headache, though subsequently its intensity was somewhat diminished by alcohol. He took his usual daily tablet of mepacrine at night.

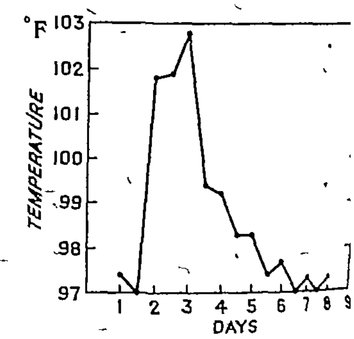

Fig. 1—Temperature chart in human case Mengo encephalitis.

Course.—On the morning of Nov. 24 the patient's headache was still severe and throbbing. About noon he began to shiver, could not walk about, and felt better lyi down in a dark room. He took some 'Veganin' and 2 of sulphadiazine.

He was examined by one of us (A. M. B.) on Nov. 24, whe his general condition was good, though his temperatu was 101·8°F (fig. 1). His pulse-rate was 84 per min. and th pulse was of good volume. His face was flushed and h conjunctivæ injected. His pupils were equal and react briskly to light and accommodation. He had some hyp æsthesia over the scalp and forehead. By the evening h headache was worse and he was delirious, with irritabilit restlessness, and delusions. He vomited three times betwe 7 and 10 P.M. Repeated blood slides were negative fo malaria and other parasites. The patient was given a tablet veganin and morphine gr. $^1/_4$ and had four hours' heavy sle

On Nov. 25 his headache was intense, generalised, an bursting in type, and he had severe photophobia. H tongue was moist and moderately furred. There was defin rigidity of the neck on flexing the chin on the chest. A arm and leg reflexes were sluggish. The plantar reflex wa flexor, and the abdominal reflexes were brisk. Hyperæsthes of forehead and scalp was still present. No abnormality o the cranial nerves was found, but the optic discs were blurred. Blood slides were again negative for parasites. The tota white-cell count was 7300 per c.mm. (polymorphs 65%, lymphocytes 33%, monocytes 2%). The patient was st very restless and mildly delirious and his temperature wa 102·8°F. He had a poor night in spite of medication wi morphine and potassium bromide, but by next morn (Nov. 26) his temperature had fallen to 99·4°F, his headach had become less severe, and he was more relaxed. Pho phobia, neck-rigidity, mild œdema of the optic discs, an hyperæsthesia of the head were still present.

Next day all signs and symptoms diminished, and th patient's temperature was normal, but in the evening he tingling of the right forearm and hand, with some numbn No abnormality of sensation or motor function was dete The white-cell count was 8400 per c.mm. (polymorphs 58 lymphocytes 39%, monocytes 3%).

By the 28th the patient had further improved. He had only occasional twinges of headache, and his

was still normal. He was allowed to get up. Next day he did not complain of any symptoms apart from paræsthesia of the right forearm. On Nov. 30 he discovered that he was deaf in the right ear and had some weakness of the upper fibres of the trapezius muscle on the right side. The deafness was subsequently shown to be of nerve type.

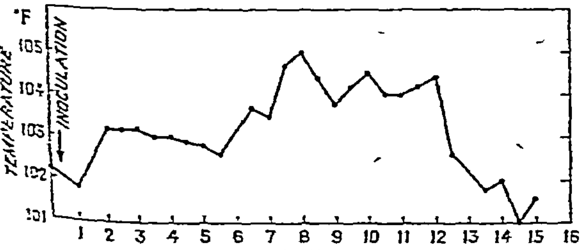
During the first fortnight of convalescence there was some weakness of the muscles of deglutition, but this and the weakness of the trapezius muscle disappeared within about three weeks. Convalescence was uneventful, and the only sequela was slight residual nerve deafness on the right side.

ISOLATION OF VIRUS

In Mice[†]

Blood was taken from the patient on the first day of illness, and the serum was inoculated intracerebrally in 0·03 ml. quantities into each of 8 six-day-old mice and intraperitoneally in 0·1 ml. quantities into 8 other mice of the same age. Of the mice inoculated intracerebrally 1 died on the first day. On the second day 2 of the mice died and 1 was incoördinated and had paralysis of the hind legs; 1 mouse died on the fourth day; 2 mice were sick on the eighth and ninth days and were sacrificed, successful intracerebral transfers being made. There was 1 survivor on the thirtieth day. Of the 8 mice inoculated intraperitoneally with the patient's serum 1 died on the second day and was used for subinoculation purposes. The other 7 mice remained well for thirty days. From the dead mouse a successful intracerebral transfer was made, a 10% Seitz-filtered suspension of the mouse brain being used. By the second passage there was 100% mortality among inoculated mice.

The average survival time from the second up to the tenth passage in mice inoculated with 10% Seitz-filtered mouse-brain suspensions was 1·2, 1·4, 1·0, 1·4, 1·2, 1·0, 1·4, 1·0, and 1·0 days. From the tenth to the twenty-sixth passage (when mouse-brain passage was stopped) the average survival time was usually less than a day. The average survival time of mice inoculated with the human strain of the virus was at first shorter than that of mice inoculated with any of the other strains except the mongoose strain (Dick et al.). Apart from this the clinical signs in mice inoculated with mouse-brain suspensions of the human strain were similar in all respects to those produced by other strains of the virus (Dick et al., Dick (a)).



In Rhesus Monkeys

On the second day of illness the patient was again bled, and rhesus monkey (MR 739) was inoculated intracerebrally with 0·1 ml. of the serum. On the seventh day after inoculation MR 739 had a slight rise of temperature (103·8°F) and next day its temperature was 105°F. Fever continued for five days (fig. 2), but no other manifestations were noted.

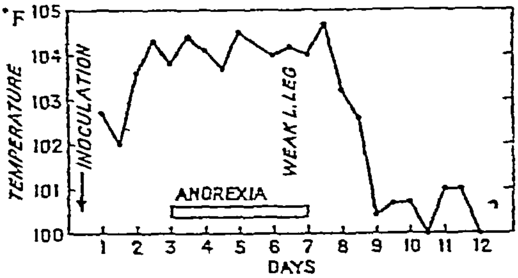


Fig. 3—Temperature chart of rhesus monkey MR 600 subinoculated with eighth-day serum of MR 739.

MR 739 was bled on the eighth day, and mice and a rhesus monkey (MR 600) were subinoculated with its serum. Mice inoculated intracerebrally with 0·03 ml. quantities of this serum behaved similarly to those receiving other strains of Mengo encephalomyelitis virus (Dick et al.). Passages of 10% Seitz-filtered mouse-brain suspensions were successful. The average survival time of the first group of mice inoculated with serum of MR 739 was a day; in the next six passages, in which mouse-brain suspensions were used, the average survival time was less than a day. From the eighth to the twenty-first passage mice were inoculated intraperitoneally with mouse-brain suspension, and the average survival time remained at about a day. Mouse-brain passages were then discontinued, and mouse-brain virus was preserved by freezing and drying and in 50% glycerin (Dick (b)).

MR 600 was subinoculated intracerebrally with 0·1 ml. of eighth-day serum of MR 739. MR 600 exhibited daily pyrexia from the second to the eighth day (fig. 3) after inoculation, and circulating virus identified as the Mengo encephalomyelitis agent was demonstrated in its serum on the second day (no other tests were made for circulating virus). From the fourth to the sixth day after inoculation MR 600 had anorexia, and some weakness in the left lower limb was evident on the seventh day. This monkey recovered completely, and both it and MR 739 developed immunity to Mengo encephalomyelitis virus as demonstrated by an intraperitoneal protection test.

In Guineapigs

Two guineapigs (nos. 173 and 174) were inoculated intracerebrally with 0·1 ml. of second-day acute-phase serum of MR 739; they died within 24 and 48 hours after inoculation. Passage of the brain of guineapig no. 173 was made to two other guineapigs (nos. 175 and 176), which were found dead 24 hours later. In all cases Mengo encephalomyelitis virus was identified in the brains of the dead guineapigs. The human strain of Mengo encephalomyelitis virus was much more virulent to guineapigs (Dick (a)) than was the original strain of virus isolated from the paralysed rhesus monkey (UR 22).

IDENTITY OF THE VIRUS

The serological individuality of Mengo encephalomyelitis virus and the relationship of the monkey, mongoose, and mosquito strains were established by neutralisation tests (Dick et al.).

The virus neutralisation test is used to demonstrate specificity of antibody for a known virus, or, with known antibody, to identify an unknown virus.

Briefly, serum which is suspected of containing antibody is added to a suspension of known virus, or vice versa, suspensions of unknown viruses are added to sera containing known antibody. The serum-virus mixtures are usually allowed to stand at room or incubator temperatures for a certain time, and animals (for the encephalitis viruses usually Swiss white mice) are then inoculated with these mixtures by a route which depends on the pathogenicity

---

[†] The mice used in all experiments were descended from the original stock of Swiss white mice from Carworth Farms near New York City. Mice used for experiments were 35–42 days old unless otherwise stated. A group of mice consists of 6 which, under routine, are caged together on weaning at 21 days.

* Numerator indicates the number of surviving mice, the denominator indicates the number of mice inoculated.
† Calculated by the method of Reed and Muench (1938). M.E. = Mengo encephalomyelitis. .. = no test made.

of the virus under test. Normal and immune control serum-virus mixtures are also set up and inoculated into groups of mice, the former to determine the titre of the virus suspension used and the latter to check the specificity of the reaction. The number of virus particles neutralised by the known and unknown sera may then be calculated from the mortality ratios of the inoculated mice (Reed and Muench 1938, Paul 1944), and the neutralising effect of the unknown serum may be compared with that of the normal and immune control sera. Similarly the degree of neutralisation of an unknown virus by a specific immune serum may be calculated.

The details of the methods used in immunological studies of Mengo encephalomyelitis virus are described by Dick et al. For the purpose of identifying the virus isolated from the above-mentioned patient the following experiments were done:

A 1 in 100 suspension in saline was made with the brain of a sick mouse which had been inoculated with fifth-passage mouse-brain suspension of the infective agent recovered directly from the human patient. The mouse-brain virus suspension in 0·25 ml. quantities was added to 0·5 ml. portions of known normal and immune sera. The virus-serum mixtures were allowed to stand at room temperature for 20 min., and mice in groups of 6 were inoculated intraperitoneally with 0·06 ml. each of a mixture. All mice remained well after inoculation with the mouse-brain virus suspension mixed with convalescent serum from a monkey (MR 692) which had been inoculated with a known strain (UR 22) of Mengo encephalomyelitis virus. There was no neutralisation of the human strain of virus by sera from known non-immune animals.

A similar experiment was done with second-passage mouse-brain virus recovered from the human patient through rhesus monkey MR 739. The virus was again neutralised by serum from a monkey (MR 692) known to be immune to Mengo encephalomyelitis virus, but not by normal sera.

The final proof of the identity of the infective agent from the human patient was achieved when it was shown that the patient's convalescent serum neutralised both the virus isolated from the patient and a known strain of Mengo encephalomyelitis virus (UR 22 strain); inactivated second-day acute-phase serum from the patient had no such neutralising power. This latter serum was inactivated by heating at 64°C for an hour. At the time of this test the pronounced stability of Mengo encephalomyelitis virus was not known, and it is conceivable that active virus may have been present in the "inactivated" specimen. Accordingly, about a year after these tests were made, another protection test was done, in which the neutralisation effect of human immune serum on the UR 22 strain of virus was compared with that of (1) a known monkey immune serum, (2) a normal monkey serum, and (3) serum taken from the human patient on the third day of illness and stored in a refrigerator. No virus was isolated from this third-day acute-phase serum, and any objection such as m be raised in the case of the original protection t could not apply. The results of these intraperito protection tests are presented in the accompany table, which shows that the convalescent human se protected mice against a test dose of 25,000 M.L.D. UR 22 strain of Mengo encephalomyelitis virus and agai at least 3170 M.L.D. of the strain isolated from human patient.

HUMAN IMMUNITY TO MENGO ENCEPHALOMYELITIS

No specific surveys have been made for the purp of studying the incidence of human immunity to Me encephalomyelitis virus; but sera collected for yell fever immunity tests have been tested for neutrali antibodies to the Mengo encephalomyelitis virus. technique used in testing these sera was similar to t of the neutralisation tests described above and has b discussed by Dick et al. The test dose of virus wa all cases greater than 100 M.L.D. per mouse; usu it was about 1000 M.L.D.

Sera from 237 persons have been tested, and 3 h been found to be immune: 1 from the patient wh case is described here; and 2 from children aged 4 an years, both living on the edge of the Budongo Fores Siba village, Western Province, Uganda. The res of the protection tests, excluding the case described, w as follows:

Area where sera were collected	*No. tested*	*No immune*
Uganda:		
Bwamba County ..	20 ..	0
Budongo Forest ..	61 .	2 (3 3%)
Toro District .. .	20	0
Kalinzu Forest	28 .	0
Various areas	30	0
Northern Rhodesia ..	39 ..	0
Tanganyika	0 ..	0
Miscellaneous	20 .	0
Total ..	236 ..	2 (0 8%)

Dr. C. R. Rainsford, senior medical officer, West Province, Uganda, kindly examined the two immu children and reported that they had no neurolog symptoms. It is planned to carry out more extens studies on the distribution of human immunity to Me encephalomyelitis virus.

DISCUSSION

The Mengo encephalomyelitis virus is so called beca it was first isolated in Mengo District in Bugan Uganda (Dick et al.), but the name is not intend to indicate that the activity of the virus is confined that district, since human immunity towards it has b demonstrated in the Western Province of Uganda.

The symptoms of the illness were those common to all forms of acute encephalitis: headache, irritability, delirium, and vomiting. Symptoms of paralysis were also present. Virus was isolated directly from the patient's blood on the first and second days of illness and identified as Mengo encephalomyelitis virus. Neutralising antibodies to that virus appeared in the patient's serum during convalescence and could still be demonstrated more than a year after the acute stage of the illness.

The source from which the patient acquired the infection is not known, and probably never will be. The patient had more laboratory contact with the virus than any of the other professional or technical staff of the Institute, yet some of the others also had considerable contact. In the period immediately preceding the illness caused by the virus the patient was the only person in residence in the Institute compound. That there was "free" Mengo encephalomyelitis virus in the vicinity about this time is attested by the isolation of the virus from a naturally infected rhesus monkey kept out of doors in the Institute grounds, from mosquitoes caught round the monkey runs, and from a mongoose trapped in the compound (Dick et al). The infection may therefore have been contracted either in the laboratory or naturally. The point is only of academic interest, since immunological studies have already shown that man can acquire the infection naturally.

The virus encephalitides of man may be divided into (1) primary virus infections with a known clinical syndrome, (2) suspected primary virus infections, and (3) infections with ordinarily non-encephalitogenic viruses (Olitsky and Casals 1947). Included in the first group are the encephalitides caused by such viruses as those of eastern (Ten Broeck and Merrill 1933), western (Meyer et al. 1931), and Venezuelan encephalomyelitis (Kubes and Rios 1939), lymphocytic choriomeningitis (Armstrong and Lillie 1934), St. Louis encephalitis (Muckenfuss et al. 1933), Japanese B encephalitis (Takaki 1926), louping ill (Pool et al. 1930), and Russian far-eastern tick-borne spring-summer encephalitis (Silber and Soloviev 1946), and by Sabin's B virus (Sabin and Wright 1934). There is evidence (Dick et al., Dick (a) and (b)) that Mengo encephalomyelitis virus is not identical with any of the known neurotropic viruses, and it may therefore be included in the list of primary virus infections of man.

The viruses responsible for most of the suspected primary encephalitides have been isolated in this laboratory. One of these, West Nile virus, was isolated from a human (Smithburn et al. 1940); and two of them, the Semliki forest virus (Smithburn and Haddow 1944) and the Bunyamwera virus (Smithburn et al. 1946), from mosquitoes. The origin of another (Dick unpublished) is uncertain, but humoral immunity to each of them has been found in man. (It is suggested that Bwamba fever (Smithburn et al. 1941) should not, strictly speaking, be included among the encephalitis viruses, since there is evidence that this virus, though highly neurotropic in mice, does not produce encephalitis in man.) Mengo encephalomyelitis virus might have remained in the group of suspected primary encephalitides if immediate and energetic steps had not been taken to find out the cause of a pyrexia of unknown origin in a man, with signs referable to the central nervous system, which was subsequently shown to be due to this virus.

Though, as already stated, humoral immunity in man has so far been demonstrated to four of the suspected primary encephalitis viruses isolated in Central Africa, nothing is known of the symptoms, if any, which these viruses may produce in man. We are therefore apparently in the unique position of having discovered the ætiological agents of several diseases whose clinical picture remains unknown. This in itself is sufficient indication for the necessity of intensified laboratory and field studies on the virus ætiology of disease in East and Central Africa.

SUMMARY

A case of encephalitis in a laboratory worker was found to be caused by a virus first isolated from animals in the Mengo District of Uganda.

The isolation and identification of this virus are discussed.

Preliminary studies on the distribution of human immunity to this virus have revealed the presence of neutralising antibodies in two children living in the Western Province of Uganda. It is therefore established that the human infection can be contracted naturally.

We wish to thank the Director of Medical Services, Uganda, and the Director of Colonial Medical Research for permission to publish this paper.

PERFORATED PEPTIC ULCER

REVIEW OF 105 CASES

A. H. SANGSTER
M.D. Dalhousie, F.R.C.S.
SURGEON IN CHARGE OF SURGICAL UNIT, BALLOCHMYLE HOSPITAL, DEPARTMENT OF HEALTH FOR SCOTLAND

PERFORATION remains the most calamitous complication of peptic ulcer. Mortality figures vary from 1·1% (Baritell 1947) to 7·7% (McClure 1940) and to 26% (Martz and Foote 1940), while Monro (1945) states that most hospital series have a mortality of 20–25%.

In 1939 I reported on 100 perforations with 24 deaths (Sangster 1939). I now review 105 with 4 deaths. The reason for this drop in mortality is at first not easy to see, but I believe it to be due to two main factors: patients in the first part of this series, being Service personnel, were in good general health; and cases in the latter half occurred after improvements in anæsthesia and postoperative care had come into use.

The average age in this series was 33·7 years, the youngest patient being aged 15 and the oldest 66 years. The general health of our patients was better than usual. Nearly half of them were in one of the Services, young, active, and outwardly healthy people. Symptoms of peptic ulceration had been present in most of the cases for less than a year. The actual figures are:

No history	24%
History of a year or less	46%
„ „ 1–5 years	25%
„ „ more than 5 years ..	5%

In 3 patients an ulcer had perforated on a previous occasion. The history of 82 patients shows that the average duration of perforation before operation was 8·7 hours. I believe this to be somewhat shorter than is usually found. Two patients in the series were not operated on. The history was typical, and radiography showed gas under the diaphragm, but all the symptoms had subsided by the time of admission. Both patients had travelled to hospital by air.

OPERATION

Operation was performed in 103 cases. It is our custom not to delay operation. Supportive measures, such as fluid replacement, serum-protein restoration, &c., are begun immediately and are continued during operation as necessary, but the operation is performed as soon as the anæsthetist is satisfied with preoperative medication.

The anæsthetist carries a great responsibility. He is entirely responsible for preoperative medication and for the choice of anæsthetic. The usual anæsthetic is nitrous oxide, oxygen, and ether. Curare has been used ever since its introduction and has definitely proved its worth in the 27 cases where it was given.

The operation has in many cases been done by one of the surgical registrars, and in some by the assistant surgeon. The essentials of the operation have been the same. The perforation is closed as rapidly as possible. No attempt is made to clean the peritoneal cavity, nor was drainage ever used. No drugs are ever placed inside the peritoneum.

The method of closure is to take a double bite of the involved viscus, with an atraumatic needle, well wide of the lesion. This suture is tied and left long. The procedure is repeated on the opposite side of the perforation. When these two stitches are lifted up, the perforation sinks into a valley. Two or three further stitches may be inserted to keep the sides of the valley in apposition. The two long end stitches are then used to tie a portion of omentum over the area.

There were 79 duodenal ulcers and 13 gastric, and 8 were placed in a category labelled pyloric. This last group includes those ulcers whose exact location could not be determined without unwarranted dissection.

The above operation was used in all but 5 patients. Four gastrectomies were performed because of massive induration; and one gastro-enterostomy. All these patients recovered.

POSTOPERATIVE TREATMENT

A postoperative régime has been instituted which, we believe, has aided the recovery of many patients—not only those with perforations.

Chest complications are largely prevented by our physiotherapists, who institute supervised exercises the day after operation. There were 7 cases of pulmonary atalectasis, none of which was serious, nor did any call for active interference. Pneumonia developed in 2 patients; one recovered, but one did not (see below).

No patient is instructed to leave his bed, but all are encouraged to do so the day after operation, and we have found that, once early rising is instituted in a ward, practically all patients wish to get up as soon as they are allowed.

Diet is important. A high-protein low-fat diet is instituted 48 hours after operation. Our dietitians provide a high-protein fluid diet based on Varco's (1946) plan modified by peace-time scarcities. The following is the fluid diet devised by our catering officer and dietitians:

VARCO I

		Composition (g.)		
		Carbo-hydrate	*Pro-tein*	*Fat*
7 A.M. ..	1/4 cup oatmeal (strained) ..	0·8	1·4	0·75
	3/4 " skimmed milk	9·0	6 3	0·4
	Glucose	—	—	—
9 A.M. ..	1 cup orange juice	24·0	—	—
	Glucose 15 g.	15 0	—	—
10 A.M. ..	Skimmed-milk powder 120 g. ..	58·8	40·4	1·2
	1 cup skimmed milk	12·0	8·4	0·5
12 (noon)	1 cup orange juice..	24·0	—	—
	Glucose 15 g.	15 0	—	—
2 P.M. ..	1 egg	0·4	6·4	5
	Skimmed-milk powder 30 g. ..	14·7	10 1	0
	Glucose 15 g.	15·0	—	—
	1 cup skimmed milk	12 0	8 4	0
4 P.M. ..	Skimmed-milk powder 120 g. ..	58·8	40 4	1
	1 cup skimmed milk	12·0	8 4	0
	Marmite	—	—	—
6 P.M. ..	1 glass fruit juice	44 0	0 8	—
8 P.M. ..	As at 2 P.M.	42·1	24·0	4
	Calories 2471 ..	303 6	155 9	17

VARCO II

Night Feed—			
Skimmed milk 30 oz.	43·5	29·0	2
4 dried eggs	—	24·0	21
Skimmed-milk powder 6 oz...	87·5	60·0	1
Sugar 200 g.	200 0	23·5	12
'Horlick's malted milk' 5 oz.	90·5	—	—
Calories about 2700 ..	427·5	130 5	41

The use of this diet has been worked out by Mr. Gav Cleland, F.R.C.S., the assistant surgeon, as follows:

1st day ..	Water
2nd day ..	Varco 2 : 2-hourly feeds of 2 oz.
3rd day ..	Varco 2 : 2-hourly feeds of 3 oz.
4th day ..	Varco 1
5th day ..	Varco 1
6th day ..	Gastric (light and high-caloric)

COMPLICATIONS

Thrombosis.—In the last two or three years we ha become thrombosis-conscious; we carefully watch fo thrombosis anywhere, but particularly in the calf muscles The nurses routinely palpate the calves of all post-operative patients, and the finding of tenderness i considered an urgent indication for heparinisation. have no experience of venous ligation for thrombosis.

Subphrenic abscess occurred twice. Drainage in on resulted in recovery, but in the other further complica tions ensued and death followed.

Paralytic ileus was found in 4 patients. All recover after the use of intestinal suction, morphine, and intr venous fluid and protein replacement. One of the patients had sprue, and great difficulty was experience in getting the bowels opened, even after bowel soun had returned to normal.

FATAL CASES

(1) A man, aged 41, admitted having perforated 72 ho before. He was a mental defective and had locomo ataxia. He was "in extremis" and died shortly af operation.

(2) A Polish soldier, aged 24, had perforated 11 hours bef admission. After operation he developed a subphrenic abs which was drained. Two weeks later further exploration the subphrenic space revealed a big necrotic area in liver. Four weeks later he developed pneumonia, follow by empyema. Toxæmia was the cause of death, but th was evidence of gross liver damage before the pneumo appeared.

(3) In a man, aged 56, necropsy showed a fulminati pneumonia.

(4) A man, aged 47, operated on for perforation h hæmatemesis on the 8th, 13th, and 21st postoperative da Transfusions kept him in fair condition, but continu bleeding set in 22 days after operation. Gastrectomy performed 30 days after operation, because blood-tra fusions could hardly replace the amount of blood lost. H way through the operation mobilisation of the duoden opened an abscess. The man died four days later fr peritonitis.

In my former series of perforations (Sangster 19 a patient died from hæmatemesis. It may not be w for one reason or another to perform gastrectomy a particular patient, but I consider that postoperati hæmatemesis should make the surgeon consider procedure.

SUMMARY

A series of 105 cases of perforated peptic ulcer are reviewed.

Of these, 103 patients were operated on, of whom 4 died.

It is suggested that recent advances in anæsthesia and postoperative care were mainly responsible for reducing the mortality to this figure from the 29% found in a former survey.

I wish to thank the medical superintendent for permission to publish this article; and the members of the staff whose efforts have so largely been responsible for the happy results obtained in most of these cases.

POLYARTERITIS NODOSA

REPORT OF A CASE

R. D. TONKIN
M.D. Lond., M.R.C.P.
CHIEF MEDICAL ASSISTANT AND REGISTRAR, WESTMINSTER HOSPITAL

R. J. V. PULVERTAFT
O.B.E., M.D. Camb., F.R.C.P.
PROFESSOR OF CLINICAL PATHOLOGY IN THE UNIVERSITY OF LONDON AT WESTMINSTER HOSPITAL

IT is curious that the presence of palpable skin nodules and eosinophilia should still be regarded as the essential diagnostic criteria of polyarteritis nodosa because for many years now the various authorities who have reviewed the subject (Strong 1928, Curtis and Coffey 1934, Harris et al. 1939, and Miller and Daley 1946) have all shown that in only a small proportion of cases is either of these features present.

Furthermore, few people realise that polyarteritis nodosa by no means carries the high mortality originally ascribed to it. Over half the patients recover, and this recovery may include complete resolution of the pathological lesions in the arteries.

Believing that the condition is about to take greater prominence in clinical diagnosis, we offer a brief outline of a further proved case.

CLINICAL RECORD

Mrs. A., aged 25, was admitted to Westminster Hospital on Feb. 2, 1947, in a state of coma, with a history of having had two fits within the past two hours. She had complained of abdominal pain over the preceding three weeks, and this had been unrelieved by alkalis. In the early hours of the morning of Feb. 2 she had a fit lasting a few minutes, after which she recovered consciousness. A second fit followed closely on the first.

An hour later, on admission to hospital, she presented the clinical picture of "rousable" cerebral irritation, but without any localising signs. Apart from incontinence, there were two outstanding clinical findings—hypertension (165/100) and massive albuminuria. There was slight fever, but of far greater significance was the fact that she showed a tachycardia out of proportion to this fever, and irregularity of rhythm. There was also early papillœdema of the left optic disc. The other systems were normal.

Next day she had a succession of ten epileptiform attacks at intervals of about ¼ hour. These ceased after the intramuscular administration of soluble phenobarbitone gr. 3.

She exhibited an irregular pyrexia over the next few days, but improved gradually to the point of coöperation. However, the disproportionate tachycardia and the heavy albuminuria persisted, and the hypertension became progressively more evident, there being a rise in the diastolic pressure to 130 mm., a level which persisted until her death three weeks later. Macroscopic hæmaturia was present on two occasions, and repeated microscopy of the urine in the interval revealed a moderate pyuria with some red cells and a few hyaline and granular casts. The blood-urea level was only 25 mg. per 100 ml.

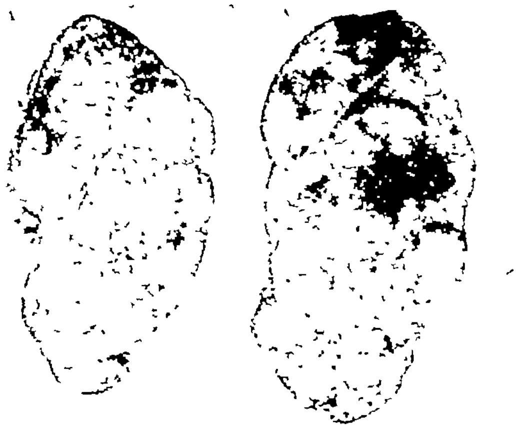

Fig. 1—Macroscopical appearance of kidneys (half-scale).

Within a few days it became apparent that she had developed a peripheral neuritis involving the left foot. The knee-jerk was weak, the ankle-jerk absent, and the plantar response lost in consequence of a cutaneous sensory loss over the foot and extending up the outer side of the lower leg.

The Wassermann reaction was negative, and the cerebrospinal fluid was normal in pressure and content. Radiography revealed no abnormality in skull, but some enlargement of the left cardiac border; the lung fields were clear.

Electrocardiography gave confirmatory evidence of widespread myocardial involvement: there were multiple premature beats in the presence of a rapid nodal rhythm, and arising from various foci. Serial tracings were taken and there was a constant change. One taken three weeks later showed definite right axis deviation, in spite of the fact that the outstanding clinical finding was that of systemic hypertension. The P waves were large and the P-R interval prolonged.

Over the next week or so the hypertension and the albuminuria remained unchanged, the blood-urea rose to 60 mg. per 100 ml., the disproportionate tachycardia persisted, and the leucocyte-count remained raised in the region of 16,000 per c.mm (polymorphs 89%). There was no eosinophilia.

The patient repeatedly asserted that she had no headache, and she was in fact remarkably free from any subjective complaints. Her indifference to her predicament as a whole, and to the paralysis of the left foot in particular, was noteworthy.

On the 16th day she developed acute left heart-failure with presystolic gallop, and extensive pulmonary œdema, but responded very satisfactorily to digitalisation. However, five days later her general condition began to deteriorate rapidly. The blood-pressure rose even further (200/130), epileptiform attacks came on again, and papillœdema became unmistakable in both eyes. A blood-count showed a persistence of the leucocytosis at 18,000 per c.mm. (polymorphs 91%),

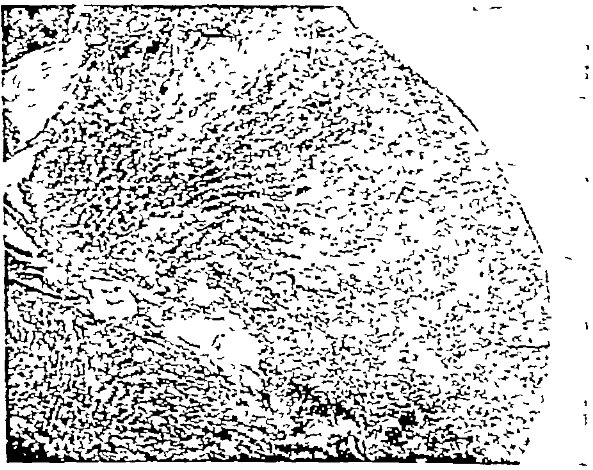

Fig. 2—Section of kidney, showing multiple small infarcts.

and blood-urea remained at 60 mg. For the last few days of life continuous morphinisation was required to control the epileptiform attacks. The blood-pressure rose further, until as a result of myocardial failure it fell shortly before death.

The total duration of illness was about seven weeks. The patient maintained a tachycardia throughout her illness, and that this was constantly disproportionate to the temperature.

POST-MORTEM FINDINGS

The outstanding macroscopical finding was extensive infarction in the kidneys (fig. 1). The infarcts were both old and recent and caused contraction and gross lobulation of the kidneys. Fig. 2 is a section of one of the kidneys, and strikingly demonstrates the secondary effects of the vascular lesions. It shows multiple infarcts, surrounded by a zone of hyperæmia, with areas of normal kidney tissue intervening.

The heart showed considerable hypertrophy of the left ventricle and minute white nodules just under the visceral pericardium and arranged along the track of small superficial blood-vessels (fig. 3); microscopy revealed that these consisted of a fibrous reaction round the vessels where the walls had given way as a result of fibrinoid necrosis. There was also a small area of infarction in the muscle of the left ventricle at the apex. The main branches of the coronary arteries were normal.

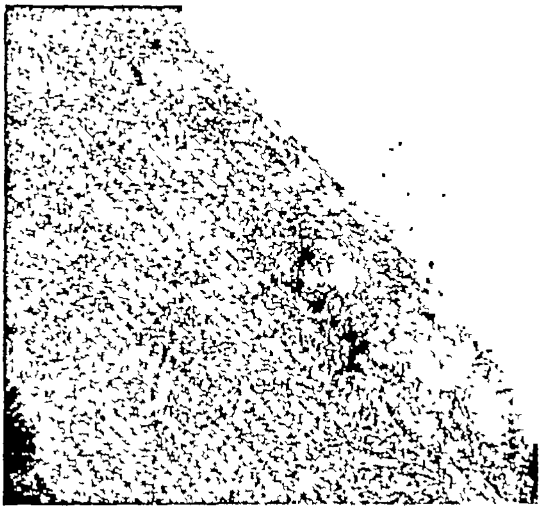

Fig. 3—Surface of heart, showing nodules along course of small pericardial vessels.

The spleen showed a solitary healed infarct. No significant abnormality was discovered in the brain.

The microscopical appearances were essentially similar in all parts, but were best illustrated in the small myocardial and renal vessels. At points along the course of the arterioles areas of necrosis in the walls were found, and segments of the circumference were absent. Thrombosis occurred within the vessel, and at the point of a local breach in the wall the neighbouring tissues had been invaded. Various stages of this process were seen in different sections: in some places fibrinoid necrosis of the wall and early thrombus formation; in others organisation of thrombus and surrounding inflammation. Most of the lesions, however, were in the stage of "healing"; the thrombus within the vessel was well organised and in some cases had even recanalised, and considerable fibrosis surrounded the lesions.

Fig. 4 shows a section of a subpericardial vessel cut diagonally. The vessel wall has given way in several places, thrombosis has occurred, and there is much fibrous reaction round the lesions. Portions of the original vessel wall remain intact. Fig. 5 shows a further stage of healing, in that the thrombus has been recanalised.

In the parts of the kidney which were not involved in the infarction the glomeruli were normal—i.e., there was no associated glomerulonephritis. This is by no means uncommon in cases of manifest polyarteritis nodosa.

DISCUSSION

Though the lesions in polyarteritis nodosa are extremely localised and constant they are very widespread and profuse. Hundreds of small arterioles in all parts of the body are occluded, with consequent production of many small infarcted areas. Since any organ in the body may be involved, the symptoms are protean; and it is this that makes diagnosis during life so difficult.

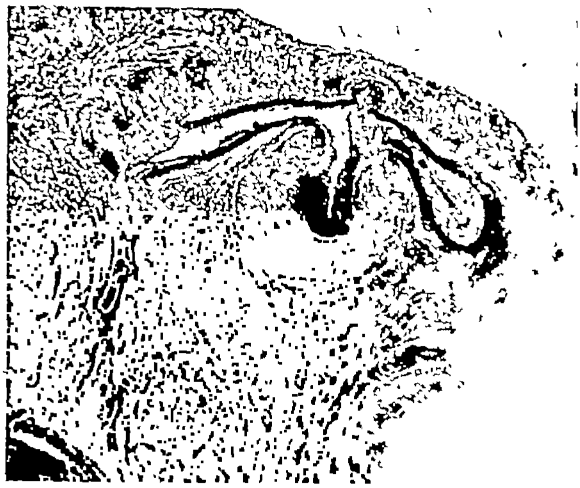

Fig. 4—Oblique section through pericardial arteriole, showing several areas where wall has necrosed and thrombus has invaded neighbouring tissue.

Many observers have attempted to classify polyarteritis nodosa into different types; but, as Miller and Daley (1946) point out, it is questionable whether this is helpful. Nevertheless it is necessary to have some basic framework on which to develop a clinical picture, for it is scarcely scientific to say that a diagnosis of polyarteritis nodosa must be considered when a plethora of symptoms is present not conforming to any established syndrome.

Harris et al. (1939) demonstrated by necropsy that pathologically the kidneys are the organs most often involved; they found lesions in 87% of cases. Polyarteritis nodosa is therefore a diagnosis that should be considered in any case which presents with a "nephritic syndrome" (in its broadest sense), and in which there are one or more additional and apparently incongruous features. The more important of these features are (1) fever; (2) persistent tachycardia disproportionate to the rise in temperature; (3) cardiac arrhythmia, or other evidence of an acute toxic myocardial process, especially a changing electrocardiogram; (4) peripheral neuritis; (5) persistent moderate polymorph leucocytosis; (6) recurrent polyarthritis; (7) abdominal pain; and (8) transient pulmonary infiltrations.

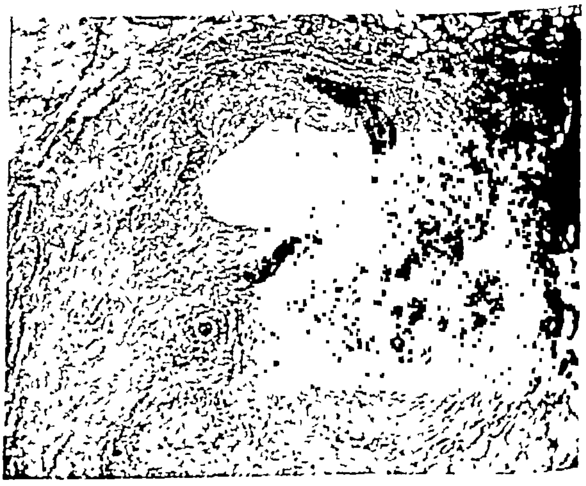

Fig. 5—Cross-section through small arteriole, showing later stage of organisation of thrombus and recanalisation.

Though the term "nephritic syndrome" has been ed here as the basic framework upon which to develop e clinical description, in any particular case the buminuria, the hypertension, the œdema, or all three, ay be absent. The two features which we regard as e most important, and the most often encountered, e (1) a disproportionate tachycardia, especially if pported by electrocardiographic evidence of wide-read myocardial involvement; and (2) a persistent oderate polymorph leucocytosis without any other lequate explanatory cause. These two features were nphasised by Lamb (1914).

SUMMARY

Attention is drawn to the fact that polyarteritis odosa only carries a 50% mortality, and that skin odules and eosinophilia, previously regarded as athognomonic, are uncommon.

A case is reported in which the clinical manifestations ere observed for seven weeks and the diagnosis was onfirmed post mortem.

The clinical picture may be pleomorphic, but there almost always clinical evidence of renal involvement. wo other diagnostic "signposts" are a disproportionate chycardia and other evidence of myocardial involve-ent, and a persistent moderate polymorph leucocytosis.

Our thanks are due to Sir Adolphe Abrahams for permission publish the case and for much help and advice, and Mr. F. King for opinion on the fundal changes.

MINIMAL REQUIREMENTS FOR MASS RADIOGRAPHY

F. C. S. BRADBURY
M.D. Belf., B.Hy., D.P.H.
ENTRAL CONSULTANT TUBERCULOSIS OFFICER, LANCASHIRE COUNTY COUNCIL

DOUBT has arisen about the value of mass radiography that the return may not be commensurate with the xpense, as foreseen from the beginning by many the tuberculosis service. One obvious method of reventing this result is to use mass radiography solely or selected groups in whom tuberculosis is expected to e more than ordinarily prevalent. This is the method sually followed at present. A drawback to the exclusive se of this method is that mass radiography would ome to be associated with susceptibility to tuberculosis, nd to be singled out for mass radiography would be antamount to being labelled a tuberculosis suspect. This seriously limits the use of mass radiography.

A better method, which could include the foregoing, would be to make sure that by adequate propaganda high proportion of the examinees in any group to be urveyed could be expected to attend for examination. There are two reasons behind this statement. First, he common-sense argument that there must be some ninimal effectiveness of mass radiography below which he procedure is not worth while. Some would perhaps place this minimum at a single person and say that if survey discovers one tuberculous person it has been vorth while; but it is not difficult to reject this extreme view. Secondly, it may be expected that if two-thirds f a large group of people agree to participate in a mass- survey and a third decline, the reasons the third to decline will lead to the existence es of tuberculosis per 1000 in the abstaining group than in the two-thirds who participate. In other words, the greater the proportion of persons examined n any group, the greater will be the percentage incidence of tuberculosis discovered, because it will more and more approximate to the true percentage incidence in the whole group.

INCIDENCE OF TUBERCULOSIS IN RELATION TO PERCENTAGE OF PERSONS EXAMINED

Survey	No. employed	No. examined	Percentage examined	Incidence of significant tuberculosis per 1000 examinees
E	8890	4675	52·6	3·6
C	34,150	20,498	60·0	4·1
D	8460	5232	61·9	4·3
B	19,940	14,338	71·9	5·2
A	13,600	10,982	80·8	6·1

That this is no mere speculation is shown by the figures relating to the last five surveys carried out by the Lancashire county council no. 1 mass radiography unit (see table).

The question now arises whether any lower limit can be fixed to the effectiveness of mass radiography, below which its use cannot reasonably be justified. Clearly such a limit must be arrived at from practical considerations. I suggest that, to be worth while from the standpoints of cost, man-power, and effective control of infection, a mass-radiography survey should discover more tuberculosis than it leaves undiscovered. To place the limit any lower than this would incur the risk of actual harm being done by a mass-radiography survey owing to the false sense of security which might reasonably attach to a group which had been so inadequately surveyed that the greater part of its initial content of tuberculosis still remained undiscovered.

If it is accepted that the limit of effectiveness of a survey is the discovery of at least half the tuberculosis in any group, it can be shown that the proportion of persons who must be examined to satisfy this requirement is about 70%. This figure is derived from the foregoing table in the following manner:

It is noted from the table that the variation in the amount of tuberculosis detected by mass radiography is almost directly proportional to the percentage response. This means that if 100% response gave 10 tuberculous persons per 1000 examined, a 40% response would give 4 tuberculous persons per 1000 examined, and the degree of adequacy with which a partial examination represents the percentage incidence of tuberculosis in the entire group will vary with the square of the percentage examined. Hence if 100% examination gives all the detectable tuberculosis, 70% response will give $\frac{(70)^2}{100}$ or 49% of the total tuberculosis in the entire group—i.e., 70% of the total because only 70% are examined; and this figure is again reduced to 70% of itself because the expected incidence of tuberculosis is only 70% of the incidence in a representative sample.

It is possible to obtain a similar result by calculation from the known incidence of tuberculosis in the general population, without the information given by the preceding table, but the calculation is too complicated for general use.

In view of the loss of time associated with the dismantling, transportation, re-erection, and testing of the apparatus each time it is moved, it is scarcely practicable to arrange a survey for less than about 4000 persons, except as part of a larger survey.

SUMMARY

There is a lower limit to the efficiency of mass radiography, below which it becomes uneconomical. It is suggested that a practical measure of this lower limit would be the point where mass radiography leaves undiscovered more tuberculosis than it discovers.

On this basis it is shown that not less than 70% of any group to be surveyed should actually be examined.

Reviews of Books

Clinical Picture of Thyrotoxicosis

PETER MCEWAN, M.B., F.R.C.S.E., consulting surgeon, Bradford Royal Infirmary. Edinburgh: Oliver and Boyd. 1948. Pp. 127. 15s.

MR. McEwan is a Yorkshire surgeon, who has been treating cases of thyrotoxicosis for the last quarter of a century. He has now condensed his experience of the disease into this little book. Its most engaging quality is its unpretentiousness, for it simply describes what the author has himself seen. Theories of causation, and of the mechanism of symptoms, are not discussed. The various phenomena which make up the clinical picture are treated individually in brief chapters—a method which makes the reader's path an easy one. The great variety of clinical types of thyrotoxicosis is much emphasised—perhaps, indeed, over-emphasised. It is not easy, for instance, to accept his contention that thyrotoxicosis is a cause of pain in the arm, though the candid way in which the evidence is presented makes it difficult to quarrel with him. Treatment is dealt with more briefly. The relative merits of surgery and thiouracil are discussed in a fair and balanced manner, and the book concludes with an interesting analysis of deaths from thyrotoxicosis, as recorded by the Registrar-General. The striking peak of deaths in 1936 is probably due, Mr. McEwan thinks, "to the hand of the surgeon," and the subsequent fall to improvement in technique. Even in 1945 at least 70 deaths were attributed to thyroidectomy, as opposed to 4 attributed to thiouracil.

This friendly little book is a welcome relief from the standardised products of modern team-work. It is easy to read, though not always easy to agree with; and it could be improved by revision.

Diagnosis in Daily Practice

BENJAMIN V. WHITE, M.D., assistant clinical professor of medicine, Yale University; CHARLES F. GESCHICKTER, M.D., professor of pathology, Georgetown University. Philadelphia and London: J. B. Lippincott. 1947. Pp. 693. £4 10s.

DESCRIBED as "an office routine based on the incidence of various diseases," this large book is divided into five parts—the diagnostic survey, diagnostic abnormalities, symptoms and physical findings, laboratory procedures, and major diseases. The authors stress the statistical aspect and assess the diagnostic significance of clinical findings largely on their incidence in various conditions. It is, in essence, the method of working from the most probable through the possible to the most unlikely; and though it has much to recommend it, this approach has obvious difficulties. Certainly diagnosis is reached by the linking up of symptoms and signs, but the cross-references and tables needed to correlate all the possible combinations are too numerous and complex. In spite of this, the book contains a mass of useful information, most of it easy to find, some much less so. Tables on the statistical survey and of normal standards, and some of the tables of differential diagnosis, are especially good. The main strength of the book, however, lies in its illustrations and diagrams, some of which—notably the coloured illustrations of skin diseases and diagramatic representations of the distribution and types of rashes—are excellent.

Vitamins and Hormones

Vol. v. Editors: ROBERT S. HARRIS, professor of biochemistry of nutrition, Massachusetts Institute of Technology; KENNETH V. THIMANN, professor of plant physiology, Harvard University. New York: Academic Press. 1947. Pp. 478. $7.50.

THIS well-produced, if rather expensive, volume is a worthy successor to its four precursors, and it carries a cumulative index. Like the others, it contains some broad surveys, which have a wide appeal and (when contemplative and properly critical) a synthetic value, and also some monographs crammed with facts. The monographs can be fully appreciated only by the specialist, who already knows the facts and who may find the account outdated, for it takes time to pro works of this kind.

In the section on *vitamins*, Melnick and Oser's account physiological availability is in the best tradition of rev articles. Thoughtful, critical, and up to date, it warns that vitamin content and availability are not synonym W. J. Darby reviews the physiological effects of pt glutamates in man. He gives a good summary of clinical experiences with them; but many more cases been reported since he wrote it, and his appraisal of therapeutic value of these substances may therefore p too cautious—a good fault in these days of new enthusia In a highly technical account of the synthesis of vitam and related products, it is rather startling to find tha of the references are to U.S. patent specifications in author's name. This article, like those on the vit requirements of the chick and the mouse, aims more at statement of facts than at their critical discussion F Professor von Muralt comes a stimulating essay—of int alike to the physiologist, clinician, and biochemist- the highly specialised work he has been directing in B on the presence and functions of thiamine in perip nerve.

The section on *hormones* opens with a detailed accoun Li and Evans of the isolation, and physical, chemical, biological properties of the hypophyseal growth and adr corticotropic hormones. Both are proteins of mode molecular asymmetry and low molecular weight. Chan and Gordon broadly survey the biology of antithyroid ag covering their physiological and biochemical actions animal species from invertebrates to mammals. S structural formulæ would have made the discussion of chemical nature of these substances clearer.

The rest of this section is devoted to sex hormones. Emm and Parkes discuss the effects of œstrogens on the m mammal. Carter, Cohen, and Shorr, in a lengthy acco of the clinical uses of androgens in women, call attention to t widely different dosages employed with apparently eq success. Many of the benefits reported cannot be ascri to specific actions, and it is hard to allow for the psyc logical reactions of the patient to hormone therapy. may have to abandon the idea of the sex hormones as s stances with single sex-specific actions. Androgens and œst gens both enter into the physiological economy of both se and many of their observed effects seem related indire if at all to sexual physiology. Heller and Maddock h contributed an article, on the clinical uses of testoster in the male, which is outstanding in its orderly developm and in the clear guidance given to the clinician on the v and the dangers of this expensive and fashionable synth hormone. Their final judgment is that "testosterone a single undisputed use. This is its application in [illegible] the signs and symptoms that attend gonadal failure du primary testicular involvement."

Misprints are extremely rare, but an irritating rash abbreviations, such as PGA, MT, ICSH, and PA disfigures some parts of the book.

Surgery of the Ambulatory Patient (2nd ed. Pl adelphia and London: J. B. Lippincott. 1947. Pp. 032. 72 —The doctors who do minor surgery are often inexperien and rely on books. Prof. L. Kraeer Ferguson, of the Univer of Pennsylvania, has provided them with one which can fail to be popular. He writes with a wide experience of subject and gives the sort of detailed information wh makes the difference between good work and bungling. T first part of the book deals with general considerations s as equipment, anæsthesia, dressings, and the conduct operations. The second covers the range of minor surge and a good deal more besides, region by region. The th part deals with fractures and dislocations. There are ab dant illustrations, both photographs and drawings, of excelle quality, and British contributions are well represented in t references.

The scope of minor or outpatient surgery is d not only by medical fashions and resources but by social economic factors. Professor Ferguson includes in his many conditions which would in England probably be t in hospital. Some of these might have been omitted in of a description of alveolar abscess, or of the right way open a quinsy—to mention only two subjects for which looks in vain.

THE LANCET

LONDON: SATURDAY, AUGUST 21, 1948

Adoption

With some 33,000 children in this country lacking family life, would-be adopters usually suppose that their only problem is to pick a congenial child. Feeling that their good intentions are a sufficient guarantee for the child's future, they are astonished at the obstacles often put in their way. Babies seem to be inexplicably scarce; adoption societies ask for details which the adopters cannot believe to be relevant; and the law imposes exasperating delay. All this is the more annoying if they happen to hear of other prospective parents who "got a child without any trouble"—without impertinent questions, without waiting, and without guarantees on either side.

Their bewilderment is fully justified, for the three legal ways of adopting a child in England today have hardly anything in common. The methods are styled adoption through a regular society, third-party adoption, and direct adoption. The last is the least trouble: the mother hands the baby to some sympathetic friend, perhaps over a glass of beer at the local, and the adopter goes through with the necessary legal formalities—or she doesn't. The child thus has no safeguards whatever. Third-party adoption offers him very little more security: a doctor, the matron of a nursing-home, a health visitor, or anybody else, can introduce a prospective parent to a likely baby; this third party is only required (and often forgets) to notify the health department of the local authority seven days before the child is adopted. The interval is intended to give the authority time to send a visitor to see and approve the home; but in practice a week is often too short. And there are other drawbacks to the method. Thus the third party may be far more concerned with the welfare of the prospective parent than with that of the child; and doctors, it seems, are particularly prone to this fault. Feeling sorry for the spinster of 50, the couple who have foregone a family because one partner has hæmophilia or epilepsy, or the neurotic widow, they prescribe a child in much the same spirit as they would prescribe a course of phenobarbitone or a month at the seaside. The results, for the adopter, may be good, at any rate at the outset; but the child is willynilly committed to a long-term engagement. His spinster mother may be old and infirm when he is yet in his teens; his adopted father's health may deteriorate, and with it the ability to support a wife and child; his widowed foster-parent may use him as the sounding-board for her own emotions, and rob him of his peace for life These are important hazards, and they ought to be considered carefully on the child's behalf. There is the further drawback that third-party adoptions are often arranged within a single neighbourhood. The child is brought up among neighbours who know his mother's history and his own; and he is always encountering his real, as well as his adopted, relations. It is only fair to the child to give him a fresh start in surroundings where nothing is known of his antecedents; otherwise he has to make an exceedingly difficult and complex adjustment. Finally, the method is open to one signal abuse: there are matrons of some small nursing-homes who make a regular practice of arranging adoptions. They cannot, of course, take money for this service without bringing themselves into conflict with the law, but they let it be known that they will undertake to find a home for the expected child, and they charge the mother a high rate for her confinement. This is clearly a most improper proceeding, exposing the child to all the risks of casual or careless placement, and the mother to something like sharp practice.

To recognise these facts is to understand more clearly the policy of the adoption societies. They hold that the important party in an adoption is not the prospective parent but the child. The adopters may be seeking an immediate solace or comfort, but the child's whole future is at stake; and he will have to pay in the long run for any error of judgment made by his would-be benefactors. The societies must therefore take their duties seriously, and in so doing many of them have the advantage of the experience that goes with a respectable age. Besides the regular societies, however, many small moral welfare organisations have in recent years registered as adoption societies in order to be able to place illegitimate children who come their way; and though this means that societies—now about 50 in all—are distributed more freely through the country than they used to be, it has the disadvantage that small societies may arrange adoptions for as few as six children a year (which gives them little experience) and are often obliged to place a child in his own neighbourhood.

The law provides general safeguards. Thus, nobody under the age of 25 may adopt a child; and a single man may only adopt a boy, not a girl. But the regular societies make more stringent rules. They have a case-committee which inquires thoroughly into the suitability of would-be adopters, and also into the health and antecedents of the child. As a rule only married couples in early middle life are approved, though occasionally a brother and sister may be accepted as joint adopters. Adoption by a single person or a widow is not encouraged, partly because the societies believe that the child needs both parents if he is to have the best possible chance of developing normally, and partly because the untimely death of a single adopting parent may leave the child stranded. The society's case-committee checks the marriage certificate of the parents, visits their home, and gets credentials of their suitability and health. The child is examined medically before he is accepted; a Wassermann test is done; and the mother has her rights explained to her. The child then goes to the parents on trial for three months—which the societies regard as a good plan because it gives everyone, including the mother, time to think things over. After three months the parents can, if they wish, consider the child for another three months, but at the end of that time they must adopt or give him back. Until the child is legally adopted the mother has the right to change her mind and refuse to surrender him, and this may fall very hardly on adopters who have come to love the child as their own. But the period of delay also has another use: it gives the parents a good chance to assess the intelligence of the child. The trial period usually starts when he is about six months old, and at this age it is not easy to diagnose mental defect, especially of minor degree. During the ensuing six months development in a normal child is exceedingly rapid; and, since the legal arrangements often take a further three months to complete, the parents (and their family doctor) have nine critical months in which to study the child's mentality and rate of development. Adoption means that parents accept full responsibility for the child as if he were their own; and many will consider that they ought to have this chance of studying him carefully before doing so. Nevertheless it is possible to be too cautious. Fathers and mothers normally receive their children as surprise packets, and sometimes the surprise is not pleasant. Some adopters, perhaps, would be willing to take the same risk, especially if it meant earlier adoption. From the psychological point of view, adoption in the first few weeks of life is preferable for both the child and the parent.

In their efforts to safeguard the child it is possible, indeed, that the adoption societies have gone a little too far. They say that since they always have more would-be parents on their books than children, they can afford to take serious trouble about finding the child a good and fitting home. But there is some reason to suppose that more children would come their way, and fewer be disposed of by direct and third-party adoption, if their investigations and precautions were a little less formidable. Their obligations would surely be fulfilled if they ensured that the baby had as good a chance of a comfortable and happy home as the average child, and that the adopters had as good a chance of getting a normal healthy baby as average parents. There is a risk that by being meticulous they may defeat part of their own purpose; they ought, as a matter of course, to be arranging nearly all the adoptions in the country, but in fact they are leaving a large proportion almost unregulated. It is important to remember those 33,000 children being brought up without any home life at all; for if most of these had been adopted in infancy they would, by and large, have had a happier and emotionally more satisfying life than they are getting now. Adopters, it seems, are not scarce; encouragement and propaganda would doubtless swell their ranks; and over some ten years they might greatly reduce the numbers of deprived children brought up in institutions, with a great gain in happiness all round. What if some of the adoptions did go wrong? There would, of course, be individual failures, some of them grievous, as there are now. But the chances are that most would turn out quite well—certainly as well as, or better than, life in an institution. The child's chief need is the direct and personal love of parents: the best physical care, the prettiest clothes, the finest grounds, the kindest nurses, and the most nutritious food are not a substitute for this.

Mastoid Surgery

To some extent mastoid surgery connotes fail in treatment. Though often there seems to be line of demarcation, acute suppurative mastoid can be regarded as a complication of acute suppurati otitis media, which is itself secondary to infectio in or near the nasopharynx. This infection trav by way of the submucous lymphatics up the eustach tube. Treatment therefore aims at arresting infection at its source and at preventing this spread. If the middle ear is already involved by the time the patient presents himself, energetic measures may succeed in segregating and finally eliminating the infection. The means employed are now matters of routine, including chiefly a direct attack on the infecting organism by some form of chemotherapy, and local applications to the site of invasion. this site is in the nose, steam inhalations should be employed—or short-wave diathermy if it is available—and also some method of nasal ventilation or sinus drainage.[1] With energetic conservative treatment of this kind from the outset, and with the patient at rest in bed, the condition will usually resolve.

Yet in spite of unremitting care and comprehensive treatment some cases progress to bone invasion and caries in the middle ear or mastoid process. Unless otherwise explicable, the persistence of purulent otorrhœa, or an abnormal unruptured drum, and deafness for a few weeks indicate such a state of affairs. At this stage a Schwartze mastoidectomy will effect a cure, but if it is not undertaken the infection may become chronic. In this sense every case of chronic otorrhœa can be considered either a failure of the treatment originally given or the result of neglect; and every student, undergraduate or postgraduate, should be taught to think it so. At present far too many cases of chronic infection still appear in the outpatient departments. Fortunately, apart from the social unpleasantness of a discharging ear and gradually increasing deafness, the patients are seldom seriously inconvenienced; but a proportion of them endure acute exacerbations of infection and complications of greater or lesser severity, and these require more energetic treatment —usually some form of mastoidectomy.

The two problems in management of the chronic discharging ear are thus (1) the selection of cases in which complications are probable, and (2) their proper disposal. The types of chronic discharging ear likely to give rise to serious trouble are fully discussed in otology textbooks. Each case must be considered individually and the decision can be made only by an otologist; after which the treatment is entirely a matter of operative technique. The operations usually employed for ablation of the disease are the radical mastoidectomy and its various modifications for disease confined to the attic region. (There are undoubtedly cases where the infection is only in the tympanum or epi-tympanum and does not apparently extend to the mastoid antrum and cells.) The classical operations involve an approach to the middle ear through a postaural incision, and this means removal of a great deal of possibly healthy mastoid bone. Such a route, it must be confessed, seems

---

1. See *Lancet*, July 17, p. 104.

nnecessary if the middle ear alone is involved and an be approached in any other way. The fathers of tology, TOYNBEE and his immediate successors, erformed intrameatal operations, for the post-aural approach had not been devised, and lately here has been a return to this type of surgery from an nwillingness to remove healthy tissue. LEMPERT's ndaural approach and TUMARKIN's intrameatal rocedure[2] are both methods of this kind. Undoubtedly hese operations have their uses but, purely on echnical grounds, time and more extensive applicaon by other surgeons are necessary before they an be included as part of the equipment of the verage otologist. Even more important, the proper election of cases is essential, especially for TUMARKIN's rocedure, and though a fair estimate can be made y clinical and radiological examination the fact must be faced that mastoid cells may be infected in egions remote from the antrum. Without exenteraion of such cells the operations will fail, and this isk must be remembered.

The Law and the Judges

THE dropping of the death-penalty amendment to he Criminal Justice Bill, even if it was a concession o prejudice, was necessary to save delay over a measure that commands wide support. It will prove benefit if it later permits a more informed and decisive verdict on the abolition of capital punishment.

But the debates have demonstrated all too clearly the weight and obstinacy of the opposition that conronts penal reform. If anyone has had illusions about the amount of ground gained for rational penology, those illusions must have been dispelled; or it is evident that the progress made is both insufficient and precarious. Many people familiar with the work of social psychologists such as HERMANN MANNHEIM, students of delinquency and penology uch as CYRIL BURT and NORWOOD EAST, and writers ike EDWARD GLOVER who have examined at length nd objectively the dynamic psychology of certain forms of punishment, must be bewildered and disppointed to find responsible persons, concerned in the administration of justice, who still clamour for the reinstatement of flogging, and who, like the statutes they administer, retain ideas of sexual delinquency which were demonstrably outmoded fifty years ago. A study of the opinions expressed by members of both Houses in these debates brings home very sharply the gap between knowledge and practice.

Actual judicial procedure in this country is in general, and within its terms of reference, fair and humane: but the attitude which the courts adopt toward the proven delinquent is often the reverse. The incongruity between the attitude of a learned judge to the sexual offender while he is on trial, and to the same offender when the time comes to pronounce sentence, is sometimes startling, and we are now faced with the anomaly that legislative efforts to reform the penal code can be frustrated by the judges. Thus to combat the increase of crime they seem to put their trust chiefly in an increasing severity of sentences. The latest report of the Commissioners of Prisons[3] contains an analysis of lengths of sentence during the years 1913, 1938, 1945, and 1946 which shows a steady fall in those of less than a month, from 78% of the total in 1913 to 22·9% in 1946, balanced by a rise in all longer ones. To some extent, of course, this is in line with advanced opinion, which sees little use in brief imprisonment as a means of reformation: the longer sentences could conceivably be defended if they gave better opportunity for psychiatric treatment or measures intended to build up social qualities and self-respect. But the truth is that our psychiatric care of prisoners is still extremely sketchy, and, owing to the crowded buildings and lack of staff, measures for their reform have slipped well below the 1939 level. Moreover, it is questionable how far the judges are thinking of opportunities to treat and reform. In the main they do not appear sympathetic to the defence of accused persons based on psychiatric evidence; indeed for some time it has been cynical talk among barristers that to call a psychologist for the defence is tantamount to asking for a doubled sentence. It is not unfair to the courts to say that their prejudices are strongest where those of most laymen are strongest; and it is precisely in those matters which have the strongest unconscious overtones—flogging, sexual offences, murder—that such prejudices operate most clearly. Unfortunately this seems to go with a growing mistrust of all scientific methods in treating and assessing delinquency—a distrust based fundamentally on an archaic faith in retributive punishment. And so long as this attitude persists there is grave risk that attempts at legislative reform will be obstructed and nullified in practice by the courts.

An increase in crime is a warning to us to reform the pattern of our society—to check the growth of insecurity and asocial behaviour which belong to that complex of militarism and centralisation termed, by GEDDES, megalopolitanism. It is also a signal that our conception of penology is obsolete, by the test of results as well as in the light of knowledge. The idea of retributive punishment is as outdated in psychology as the idea of human sacrifice in religion. The Criminal Justice Act is welcome as a step in the right direction, but we should be ready to go considerably further. Some of our prisons, with their anonymity, their slum standards of hygiene, their dietary punishment, and their assault on the self-respect of the criminal are under the same condemnation as the cat and the gallows—they are condemned both by their results and by their theory. How desperately bad conditions now are has lately been explained by the penal reform committee of the Society of Friends.[4]

The conservatism of the judges has in the past gained important victories for the rights of the individual, and the administration of justice, which they represent, is not a field into which medicine can reasonably intrude. But the disposal of convicted offenders is another matter. To attempt to remove all judicial control over such disposal would be a dangerous step for civil liberty: but penology is a field in which psychology and the bench ought to meet on a basis of coöperation, in the interests both of society and of the offender. Unfortunately the attitude of the law today, the cynicism of the courts towards medical testimony, the absurdities of the

McNaghten rule, and the fundamental unreason of many features of the penal system which the courts uphold with enthusiasm, all render a direct conflict far more probable than any such coöperation. The outcome of such a conflict cannot be doubted, but it may well be protracted and bitter. Not only the criminal, but the public at large—the chief concern of the reformer as well as the court—will inevitably suffer; and such a struggle between science and authority (already manifest in the difficulty which independent psychiatrists have found when required to testify, or to treat patients under existing conditions) might well do serious damage to Western conceptions of justice and humanity.

Annotations

THE MENTAL HEALTH OF MANKIND

PROSPECTS of righting the world in time to prevent another pandemic war seem so poor, and the obstacles to world citizenship so formidable, that the able and earnest group of psychiatrists, clergy, ethnologists, philosophers, social workers, and others who have gathered for the International Congress on Mental Health inevitably wear something of the forlorn aspect of Jack the Giant Killer. In that trial of wits, however, it was the giant who finally fell to the ground; and indeed in the history of mankind the mere size of a dilemma has never been the deciding factor in victory or defeat. There is no immediate way out of our trouble: but at least, speakers at this congress have shown where we may begin to lay our roads. In a contribution full of wit and factual knowledge Dr. Margaret Mead (reported on p. 303) outlined the principles and standards in the upbringing of children which help to form a responsible personality. Guilt may be good or bad; a sanction which obliges us to observe the duties of citizenship, or a paralysing burden which hampers and delays all mental growth. Aggression may turn inward on the self or outward on the world, and be useful in either phase—in moderation. An exceptionally interesting observation was that made on American and German soldiers who broke down under stress of war: in Americans the conflict was between the acts done and the standards of right and wrong in which the young men had grown up; in Germans the conflict commonly arose over failure to obey an officer, the father figure. If the inculcation of personal responsibility is to be the aim of upbringing, the American and English system has so far achieved it better than other methods.

Other lines of thought have been set out in the statement by the International Preparatory Commission which appeared this week. This commission, drawn from ten countries and appointed on behalf of the congress, met in advance under the chairmanship of Dr. J. R. Rees, to consider and report on group studies. These studies have been sent in from twenty-seven countries where mental-health problems have been considered during the past year by some 5000 men and women in varying professions. Much of the material in this document is general, directed to improving mental-health services in every country, and to providing guiding principles; but it is based on two clear conceptions. Though important elements of the personality are acquired during the early months of life, these early influences are not final determinants; no single stage in maturation decides ultimate success or failure, since good influences later can modify early distortion. And though man is much moulded by his institutions—which may be good or bad—yet institutions are not permanent: they change, and social patterns of behaviour change with them. Thus in our first blundering steps towards world citizenship we are not confronted, as somet appears, by the stone wall of an implacable antago but only by our neighbour's movable hedgerow.

ARTIFICIAL INSEMINATION

THE Archbishop of Canterbury's Commission Artificial Human Insemination included well-balanced elements, ecclesiastical, medical, and legal. Its report is unanimous in accepting "assisted insemination" as a sequel to normal intercourse (or the attempt at i between husband and wife. Eleven out of its twelve members agree that, if assisted insemination is inapplicable, artificial insemination with the husband's semen may be employed. By the same proportion it condemns artificial insemination with semen which is not that of the husband and it recommends that this practice be made a criminal offence.

The chapter of the report which deals with the legal aspects, written by Mr. Justice Vaisey and Mr. H. U Willink, K.C., is important, especially as it describes a "superficial and indeed grossly misleading" a note issued by the Medical Defence Union. It begins by suggesting that artificial insemination by the semen of the husband, assisted by mechanical means, might possibly be a ground for granting a decree of nullity if recourse were had to it with a total wilful exclusion of normal intercourse. As regards insemination by the semen of someone who is not the husband, a medical practitioner who administers it would, in the opinion of these two eminent lawyers, be an accomplice in fornication or adultery; they suggest that the medical profession might feel bound to formulate some new principles as to what is and what is not proper professional conduct in these matters. They are convinced that the use of semen of a donor who is not the husband constitutes adultery: here they quote Lord Dunedin's opinion given in the House of Lords in 1924 in Russell v. Russell:

> "The appellant conceived and had a child without penetration having been effected by any man; she was fecundated *ab extra* . . . the jury came to the conclusion that she had been fecundated *ab extra* by another man unknown, and fecundation *ab extra* is, I doubt not, adultery."

To this dictum of Lord Dunedin they add another from the Ontario Supreme Court's decision in Orford v. Orford (1921) which held it possible that such an act, performed upon a woman against her will, might constitute rape. They think that the device of mixing the semen of the husband with that of a donor or donors would in no way affect the question of adultery. The two legal experts mention with respect an article by Sidney Schatkin [2] on the question of the illegitimacy of the child. They appear to agree that, if the child is not the husband's actual offspring, it will be illegitimate even though the husband has freely consented to the insemination.

They then draw attention to the serious consequences of registering the child in such cases as the child of the husband. This, they say, would be a criminal offence, punishable with seven years' penal servitude, under section 4 of the Perjury Act, 1921. They express surprise at a statement [3] that "the couple are informed that the child will be legitimate if the husband is registered as the father; such registration is demanded, although it constitutes an offence." "The practitioner," they remark, "must be perfectly well aware that the couple to whom he gives his services are intending to make a false and fraudulent record of the resultant birth and is in truth the instigator of and accessory to the crime." They criticise the assurance suggested by the Medical Defence Union as proper to be obtained by the doctor—"that the birth of a child will not defeat

the claims of any person to any titles, estates, interests, or funds"—as one that could never properly be given or accepted.

Among other legal aspects of the matter they mention the "involuntary incest" which might occur (through the unsuspected mating of children of a common father) if the practice became frequent. They go on to consider the consequences of the insemination of unmarried women. The motive here might be the innocent one of a desire for motherhood, but it might be a wish to deceive a man into the belief that the woman was pregnant by him. It is, they conclude, the function of the law to prevent, and not to facilitate, fraud and deception. They therefore recommend legislation to make insemination by the semen of some donor other than the husband an unlawful act. Although their other colleagues accept this conclusion, the Dean of St. Paul's in his dissenting memorandum observes that, if the practice is already unlawful, legislation may be unnecessary and anyhow the proposed law imposing penalties would be difficult to enforce.

On the eugenic, psychological, and theological aspects of this problem readers will study the report at their leisure. The legal aspects seem to require urgent attention.

INTESTINAL LAVAGE IN RENAL INSUFFICIENCY

THE developments, made independently by Kolff,[1] Murray,[2] and Alwall,[3] in the treatment of renal failure by extracorporeal dialysis, have stimulated much dormant surgical enterprise in the same field. Experience with peritoneal and intestinal lavage is increasing steadily; and Odel, Ferris, and Daugherty [4] [5] have now added 2 more cases to the records.

In the first of these a man of 22, with a final post-mortem diagnosis of chronic nephritis and bilateral congenital cystic disease, was treated by the passage of a Willson-Sawyer tube 108 in. long, with a duodenal tube attached to the proximal 36 in. The intention was to effect inflow in the second part of the duodenum and outflow by suction through the longer tube, thus gaining dialysis through about 72 in. of jejunum. But intubation was difficult, even with sedatives, because of uræmic vomiting. This became paroxysmal when perfusion was ultimately started. Suction was then tried through a catheter into the tip of the appendix. Tenesmus developed, and a high rectal tube was passed. It was then found that most of the dialysing fluid—dispatched through the nasal tube—was by-passing the appendicostomy catheter and being recovered per rectum. The patient died, stuporose, with pulmonary œdema, within two days. No conclusion was possible about the efficiency of the dialysing fluid in this case ("P" solution of Odel and Ferris [6]), but the experience showed that the chief difficulties to be overcome were technical—intubation during uræmic vomiting, and the recovery of sufficient dialysate to eliminate excessive resorption. It was suggested that the first difficulty might be dealt with by irrigating through an appendiceal tube and recovering rectally, thus substituting the large intestine for the small; and the second, if duodenal intubation were still used, by inserting a much larger tube through a cæcal stoma.

Appendiceal irrigation was tried in the second case. A man of 39 with chronic nephritis (blood-urea 188 mg. per 100 ml.) had a catheter inserted into the appendix and dialysing fluid was passed through the colon to a rectal tube. Lavage was kept up for 64 hours, with some disability from nausea and abdominal cramps. Perfusion had to be stopped, however, when it was found that a hyperchloræmic acidosis with œdema was developing, even though the solution used was believed to be "physiologic" for the intestinal wall. Daugherty and his colleagues [5] comment that the wall of the colon seems to possess characteristics different from those of the peritoneal membrane in so far as exchange of chloride is concerned. Moreover, in 64 hours the blood-urea was reduced only to 112 mg. per 100 ml. They therefore agree with Kolff that for treating renal insufficiency the method is of dubious value.

TOWARDS AN ORDERLY WORLD

THE destructive power of arms has now reached a point at which civilisation could destroy itself almost overnight. Therefore (so it is argued) the nations must either abandon their sovereignty, and submit to some kind of international control, or perish. In propounding this familiar thesis Professor Mander [1] supports it with another—that the world must unite because its several parts are already too interdependent to function efficiently alone. His aim therefore is world unity by agreement, and by way of preparation he provides a factual review of all the attempts so far made to create international order. This review may be described as a constitutional history of the world as a whole; and in telling the story of our past failures and partial successes in constitution building he hopes to convince us of the urgent need for a united structure that will endure.

The reader's first response may well be pleased surprise that there are so many efforts of this kind to record. In broad outline he will already know about the attempts represented by the Hague Convention, by the League of Nations, and now by UNO, to reduce the ferocity and then the probability of war. But he may well be unaware of the enormous amount of detailed work, in many different fields, already done (and sometimes undone) to organise the world. The maintenance of health, the prevention of crime, the establishment of communications, and the conservation of resources—these are all objects that can be achieved more advantageously on an international than on a purely national basis. Again, in matters such as the regulation of labour standards and the protection of minorities, humanistic rather than utilitarian motives have been at work and have gained notable successes. In Professor Mander's view, a major reason for our failure to achieve security has been that we tried to achieve it by disarmament, which is impossible until security has been achieved. But an important movement in the direction of security is the development of a large body of rules which, though they are not enforceable by any international authority, Professor Mander regards as international law. Whatever the nations of the world have agreed to respect he would regard as law, even though their power to enforce it depends only on the continuation of such agreement. Despite setbacks, international law of this kind has been increasing in prestige.

With all this encouragement, however, the critical reader will also find his doubts and misgivings stirred; for a history of the attempts to unite the world in prosperity and peace is, after all, a record of past failures, and the latest edifice of international security already shows ominous cracks. At times peace and world order look as remote as ever, and the explanation must surely be that for most people they do not represent the highest values: they have not been worth purchasing on the terms so far offered. In the last resort nations are unwilling to buy peace at the cost of what they feel to be ideals; and since ideals cannot be proved either true or false, and will remain diverse, it may

be said that international equilibrium can never be secure enough to justify disarmament. On the other hand, if we cannot prove ideals, we can prove things about them; and if we could prove to our potential opponents that they would be happier by exchanging theirs for ours the period of vigilance would have an end.

CHEMOTHERAPY OF LEPROSY

REPORTS on the efficacy of sulphone drugs in leprosy accumulate. Davey[1] says that at the Uzuakoli Settlement in West Africa 17 patients with lepromatous leprosy, after long-continued but largely unavailing treatment with hydnocarpus oil, were treated for from five to ten months with 'Sulphetrone,' which proved relatively atoxic in the dosage of 3 g. daily six days a week. The general condition of all of them improved, and in all but 2 there was moderate (8 cases) or marked (7) retrogression of the leprotic lesions, though the bacteriological improvement has not so far equalled this. In some patients the drug produced a mild lepra reaction. In 11 of the 17 the lepromin test changed from negative to positive, indicating an allergising action.

Johansen and Erickson[2] record briefly their experience in treating lepromatous leprosy with 'Promizole,' whose effect they find comparable to that of 'Promanide' and 'Diasone.' It is slightly less toxic than the other two but it has to be taken in doses 6–8 times as large; the daily consumption of 12 to 18 tablets over long periods is unpalatable and distasteful, and as its cost is high they propose to abandon it in favour of the other sulphones. With long-continued sulphone therapy 2 of their patients became bacteriologically negative.

Faget and Erickson[3] describe severe toxic effects from the continued treatment of leprosy with relatively large doses of streptomycin. Though benefit has not been conclusively demonstrated, they believe that clinical and bacteriological improvement has followed both injection and local application. Investigation, they think, should go on.

SOCIAL SERVICE

> "We sometimes fail to realise how fundamental to the health of a democratic society is the volunteer—the man who, in addition to doing his daily job, is ready freely to give up part of his leisure for some cause or other that he believes in. . . . These people who care about causes; the adherents, the supporters, the belongers; the Chairmen, the Treasurers, Secretaries, Committee Members; they have a special significance in our society."

Mr. Herbert Morrison, addressing the annual meeting of the London Council of Social Service on July 12, was discussing the statutory pattern which, in our country, fits into and complements the voluntary pattern. As an example of statutory social advance he talked of our educational system. We are short of everything we need, he said: teachers, buildings—everything except children, though we could do with more of them. But already we have 9000 more teachers than we had before the war, and we hope to have nearly 50,000 more by 1952. Over 400 new schools are being built, and 52% of all children are now having dinners at school, compared with 4% before the war; 88% now have free milk. Under the further education and training scheme State scholarships, with full maintenance grants when necessary, have been more than doubled, and these are apart from local-authority awards. Other examples which he quoted were the National Insurance and Assistance Acts, the encouragement of food-production by the State, the National Health Service, and the provisions for the disabled. Interlocking with all these is the work of the bodies like the London Council of Social Service.[4] During the year the numbers of local councils in the London boroughs have multiplied, and—thanks to the powers now given to local authorities to provide entertainment—arts councils are being set up in many places to serve the leisure needs of the community. It has been found that community associations and centres, though they suit some parts of London, are inappropriate to others. In districts where there are large blocks of flats, small housing estates, or groups of prefabricated houses, small clubs are more welcome than neighbourhood units. The council's development officer has helped to start such clubs in many places. The plan has been first to find out by means of a questionary what kinds of things the tenants would like to do in their spare time; and a team of students from the London School of Economics has helped considerably with these surveys. The Goldsmiths' College, New Cross, has provided a training course for those undertaking work at community associations and centres. The welfare of old people is receiving more and more attention, and some 200 clubs have now been established for them in various boroughs. Mobile meals are provided in 17 areas, and 8 homes or hostels for old people have been opened during the year, with more to come. The National Corporation for the Care of Old People is supporting this aspect of the council's work with a grant for two years. Citizens' advice bureaux have been maintained, though—since local authorities are now beginning to set up their own information bureaux—they are fewer than they were during the war. The 67 bureaux directed by the council dealt with 101,130 inquiries during the year; and this year, as a result of new legislation, even more queries are expected.

GLUCOSE AND PHOSPHATE IN DIABETIC KETOSIS

OPINION has been fairly equally divided on whether to give glucose as well as insulin in the early stages of treatment of diabetic acidosis, while the blood-sugar is still high. From comparison of results in a small series Franks and others[1] argue that its use is disadvantageous. The differences they record in mortality may not be significant, but it is noteworthy that the patients receiving glucose required about twice as much insulin as the controls; the CO_2 combining power of the serum returned to normal more slowly; and there was no difference in the rate of disappearance of ketosis. Study of the chloride and water balances suggest that, through excess glycosuria, the maintained diuresis in the glucose series actually led to cellular dehydration.

The same authors[2] have also made observations on the phosphate metabolism in diabetic coma. It has long been known that there is a phosphorus diuresis during the onset of diabetic ketosis, and that insulin treatment is followed by a sustained fall in phosphorus excretion and in the inorganic phosphate level in the plasma. The effect, therefore, was tried of infusing 500 ml. of a buffered phosphate solution containing at first 1·3 g. and later 2·6 g. of phosphorus. This infusion kept the phosphate level in the blood normal, and direct evidence of phosphate deficiency was afforded by the failure of blood-phosphate to rise and by the absence of phosphate diuresis, even after the larger quantities. From the clinical standpoint the most striking effect of the phosphate was an immediate improvement in the patients' mental condition and diminution in fatalities. There were also signs of improvement in carbohydrate utilisation and a rise in CO_2 combining power.

These results need further confirmation, but they suggest that in treating diabetic coma glucose should not be given until the blood-sugar has fallen towards normal, and that intravenous phosphate infusion should be given about 4–8 hours after insulin treatment is begun.

INTERNATIONAL CONGRESS ON MENTAL HEALTH

THIS congress, under the presidency of Dr. J. R. REES, opened in London on Aug. 11 and continues until Aug. 21. It is three conferences in one. The first, the International Conference on Child Psychiatry, was concerned with personality development in its individual and social aspects, with special reference to aggression; the second, the International Conference on Medical Psychotherapy, took guilt as its main theme; and the third, the International Conference on Mental Hygiene, has this week been considering mental health and world citizenship.

CHILD PSYCHIATRY

Aggression and Emotional Development

Prof. **FREDERICK ALLEN** (U.S.A.) said that aggression was a fundamental characteristic of all living organisms. Although literally aggression meant "going towards," its usual connotation was one of attack and trouble. In theory, aggression had been made the basis of the death instinct; this was in sharp contrast to the speaker's view which equated aggression with life.

The early reaching out of the infant for food, his first aggressive act, was in response to the disturbance of his own internal equilibrium. Two separate life forces thus became interwoven—the infant roused to action by his physiological needs, and the mother figure upon whom he depended for food to satisfy his needs. Parents could become slaves to the child's demands, or they could become autocrats seeking docile obedience. The important point in the differentiating process between child and adult was the constant interplay, coloured by all the factors that made for healthy development or for unhealthy struggles and turmoil. As the expression of the individual's vitality, aggression was translated into action and then into feeling towards the limiting impact of an organising force represented by the parent. A certain amount of frustration was always associated with this impact.

To some extent all habit training was characterised by negative reactions. As the training efforts became charged with anxiety and rigid control, the greater would be the child's need to defend himself against being changed. Aggressive feeling was displaced to important anatomical areas involved in training; and these—the mouth, urethra, and anus—became associated with frustration of individual drives for omnipotence. Rigid and unimaginative efforts to regulate the feeding needs of the infant might accentuate the negative component in the early aggressions, and were the basis of many conflicts between child and parent, and later between child and society. Training in habits of cleanliness, involving urethral and anal control by the child, provided familiar areas of struggle. Negative aggressiveness was often focused on the functions of bowel and bladder. The enuretic boy who said "I want to be dry but I don't want to be made to be dry" expressed the common dilemma that emerged in the struggle between the parent requiring bladder control and the child fighting against it.

In the normal process of differentiation the child found media for expressing and organising his negative aggressions, other than in overt behaviour reaction of the "I will not" type; important media were his play and his fantasy life. Every human being reacted negatively, in some degree, to being changed; and the fantasy life of all people from childhood revealed negatively toned aggressive feelings and ideas related to the organising forces impinging upon them.

> "Each individual," Professor Allen concluded, "has a conflict in himself in organising his potential for aggressive action, either by using and adjusting to the framework provided for him to organise his individuality, or in feeling their restrictive or frustrating power and setting himself against their limiting influences. Out of the interplay rises the dynamic of aggressive action. . . . It is essential to avoid a *point of* view that regards the more positive values of aggressive action only as substitutes and diversions of the malignant quality assigned to aggression as a destructive force. . . . We want more of our children to develop the capacity to 'aggress and find their place.'"

Describing her observations on war orphans, Dr. **NELLY TIBOUT** (Holland) said that their reactions included identification with the aggressors, suppression of all emotion, depression and guilt-feeling, and depersonalisation.

Miss **ANNA FREUD** suggested that much of a person's emotional life was spent in a struggle to rid himself of aggressive feelings. From the admixture of love and hate arose many fantasies, day-dreams, religious conceptions, and utopias; in all the aim was pure love, but this did not exist in the human. There was wide divergence of opinion on the meaning of "aggression." By some it was restricted to attitudes and actions which were hostile, damaging, and destructive, while by others it was taken to include all active and constructive tendencies; by some the term was used to signify the act of aggression only, by others to include the attitude or urge from which the act originated; some schools considered aggression to be an inborn instinctive urge, while others regarded it as the product of environmental influences. According to the Freudian theory the aggressive urges represented one of two fundamental instinctive forces—i.e., the destructive instinct or death instinct. Their counterparts were the sex urges which represented the life instinct. Normally the development of aggression was intimately bound up with infantile sexuality.

In winding up the subsequent discussion, Dr. **EMANUEL MILLER** contended that what was regarded as aggression in an adult might not be aggression in a child.

MEDICAL PSYCHOTHERAPY

Genesis of Guilt

Dr. **H. G. VAN DER WAALS** (Holland) distinguished between "guilt-feeling" which was endogenous, and "guilt" which was not. Psychological studies had made it clear that conscience was capable of doing harm to the personality as well as good; and it was the undeveloped, or archaic conscience of infancy which was harmful. Psycho-analysts properly studied not guilt but guilt-feeling, and its related anxiety—the anxiety, that is, of the ego towards the superego. This anxiety was associated with fear of consequences, and as long as punishment was feared no true conscience developed. Defences against guilt associated with the unconscious need for punishment interfered with the normal conduct of life, and was even disastrous to true morality.

The Rev. Father **THOMAS GILBY** set out the Roman Catholic view, in which guilt was held to be a healthy symptom of recovery, not a morbid condition, and was inherited as part of human nature. Man was a creature, and as such exposed to conflicts—the first being a conflict against the general condition of creatureliness, the second in resentment against his animal nature, the third a conflict between spirit, or mind, and matter. Possibly the sentiment of guilt was at first a sentiment of separation from where one would want to be; and he distinguished "fault guilt" which was a turning away from the good, and "penalty guilt" which was a turning towards something else. The first was the concern of the priest: the second, when it implied turning towards a bogus form of guilt, was of great importance to the psychologist. Expiation itself was a function of health, of being on devout and friendly terms with our environment. Morbid guilt took the forms of desire to assert innocence, desire to seek impossible reassurance, and the fallacy of fixing on another object as a substitute or scapegoat.

Dr. Angelo Hesnard (France) said that morbid guilt (considered as a biopsychological fact, having no connexion with the ethical or social facts of normal guilt) was generally expressed by the "feeling of guilt" and the "need of punishment." In Freud's view, the strict early ethics of the superego—embracing the external prohibitions of the œdipus situation—derive from a primitive human tendency to self-destruction (masochism). Later the growth of sexual needs intensified this masochism (which was, in fact, the aggression which went with *libido turned inwards, on the ego, instead of* outwards) and provoked a new strictness in the superego. The neurotic sense of guilt was the result. Freud's pupils had modified this theory in various ways: tracing the sense of guilt not to primitive masochism but rather to infantile aggressive hate turned inwards on the self, reaction to training of the alimentary functions (Melanie Klein), protection against the danger of punishment, castration or withdrawal of love (Ernest Jones), or desire for punishment as a preventive of frustration (Reik, Alexander). Adler held that the neurotic adopted the attitude of a hero in face of humiliation both as a protection against inferiority feelings, and in an attempt to dominate his environment; while some of the neo-Freudians underlined the social and cultural factor in self-punishment. Regarded subjectively, guilt was behaviour which at the conscious level implied a lapse (without foundation in fact) and its punishment; and which could be recognised, on analysis, as an attempt to adapt to a prohibition threatening a "personal ethical value." It was associated with emotional frustrations and setbacks, and was connected with the œdipus situation. Objectively, it was seen to be behaviour showing the conflict between sexual and aggressive behaviour and the demands of the social and cultural environment.

In the discussion which followed Dr. Ives Hendrick (U.S.A.) noted that guilt in the grown person derived from the child's relation to authority; and it was striking, he said, how often people became in time like the parent they most resented. At a recent conference to study the German character it was observed that a nation had a culture which put into power people of a certain character; and to change the character structure of a nation and its leaders we must do more than change ideologies—we must change the family environment.

Dr. P. J. Reiter (Denmark) thought there was evidence of a primary instinct for detecting what was a good and what an evil action.

Dr. Jenny Roudinesco (France) remarked that stealing in children did not derive from a wish to do wrong but from the knowledge that by their action they could hurt someone else. The *untreated result might be per*manent guilt-feeling or even masochism. Dr. Samuel Lowy defined guilt as the emotion about things done, conscience as the emotion about the choice of things still to do. Unless guilt was satisfying a religious need, he said, it was a morbid phenomenon with no known function. The patient must be encouraged to concentrate on conscience, to say to himself, "How much more energy can I liberate for work in the world by getting rid of guilt." Guilt could be an enemy of conscience.

Mme. Maryse Choisy-Clouzet (France), who had made observations on lions and tigers "because these animals are so ambivalent," felt there was no rigid frontier between psychology and religion where guilt was concerned; sin was the sacred part of guilt, which was a neurosis. (Even a lion who has absent-mindedly eaten his friend, a great Dane, can feel guilt and sorrow it seems.)

In summing up, Dr. Ernest Jones pointed out that two views of guilt had been upheld: either that it was inborn or instinctive, or that it was due to incorporation into the personality of parental and environmental inhibitions. We did not know which was true, and we must work to find out. It was clear, however, that guilt did not develop along a straight line but interacted with other emotions. Thus fear gave rise to guilt, and guilt to fear; hate gave rise to guilt, and guilt to hate.

Guilt and Dynamics of Psychological Disorder

Prof. D. Brinkmann (Switzerland) discussed the pamphlet recently published in Zürich by Carl Jaspers on the "Problem of Guilt." This writer classifies guilt under four headings as *criminal, political, moral,* and metaphysical. In the first case the guilty person has offended against the laws, and the judgments established by the courts; in the second against the government the citizens have been responsible for choosing. Moral guilt arises because he is responsible for his actions, and feels guilt when he offends against his moral standards; metaphysical guilt arises because there is solidarity between man and man, and all are responsible for failure of justice in the world. Professor Brinkmann felt, however, that the moral and metaphysical guilt conceptions in this classification are full of contradictions. For instance, the tragic metaphysical guilt of the ancients cannot be classed with the Christian metaphysic. The Greeks saw man as the opponent of an all-powerful fate, while the Christian idea does not recognise fate at all. Man, in the Christian view, is subject to a personal God; and Western man always falls into the temptation of making himself into a saviour and seeking his own redemption. Guilt, indeed, is not a problem but a mystery; and only by active participation can we illuminate it from within.

Dr. John Rickman described the situation in which the psycho-analyst collects his facts. He listens to whatever the patient says in free association, and regards no two ideas as irrelevant if they occur in the same stream of association. He thus sees guilt in a wide context of personal experiences: not in relation to religious beliefs as the clergy must, not in relation to abstractions as philosophers choose to do, but as the patients find and feel it within themselves. Guilt is regarded as a painful tension arising between an individual and a code of behaviour—sometimes of human origin (the code of conventions in which he is brought up), sometimes of religious origin. The tension thus arises from an interplay of the person with the *environment: from an absorption of part of the environment into the self.* Thus conscience is an incorporation into the personality of parental injunctions. Both parents are loved by the child, though one is the rival in his erotic life; disobedience to the incorporated parental injunction means a pang of guilt and a fear of retribution—and moreover a sense of separation from the parents, and hence of *loneliness and depression*, coupled with the retribution-anxiety. Guilt and anxiety thus interlock, and it is hard to distinguish clinically a pang of guilt from the persecutory anxieties which also limit freedom of action and inhibit social and personal growth. Of various kinds of deep-rooted secondary mental distress, depression and the feeling of persecution, he said, were specially relevant to the topic under discussion. Depressive pain is felt when we have done or intended an injury to a loved object. Persecutory pain comes when we project on to the outer world feelings of hostility which we cannot tolerate within ourselves. When an emotional situation affecting ourselves and those we love d depend on is fraught with too much pain and is pressed, it continues to influence our mental life, and ere is an urge to resolve or complete the unfinished uation, even though we no longer know what it is want to complete. Depressive guilt, which contains large element of love, can be culturally valuable. art of the aggression is turned on the self, instead of to a loved person, and this inturned aggression ovides energy for the superego (or conscience). But e superego draws strength from the loving impulses well. The desire to please and draw nearer to the rents by obedience later becomes a wish to serve and are in the community. The reactions to guilt may a drive to restitution, a compulsive urge to propitiation, denial of the aggressive tendency, absorption in and the same time repression of the aggressive tendency, mpulsive or expiatory life patterns, sexual anomalies, eurotic or psychotic compromises, and even an interest religious and charitable organisations. Can the numbing and distorting effects of guilt on growth be itigated? Much depends on the upbringing of children. is hard for children to grow up in a broken home ithout acquiring an extra burden of guilt. Because his ambivalence the child will always unconsciously el some responsibility for the broken home. A home potentially broken if a parent uses the child's affection a weapon of defence or offence against the other parent. he child's guilt begins early, and so does cultural straint on his aggressive and asocial impulses. By he time he is four he can be described as a "cultural ait." A parent's failure to recognise the child's capacity r guilt is a failure to recognise that he is human.

In opening the general discussion, Dr. J. H. VAN DER OOP (Holland) held that a healthy feeling of guilt, s distinct from a neurotic one, is a useful social factor; nd that the superego is also valuable and important, nce we have now lost our primary instinctive directives. owever, society often demands not the optimal but e maximal degrees of repression, and the resultant nsion helps to cause the aggressive states which lead wars.

Dr. CLIFFORD SCOTT said that the restitutive aspects of uilt are often helpful since they lead us to desire know, understand, and live peacefully with our ighbours. Moreover, the unconscious capacity to ve can be used to resolve the guilty state.

Dr. K. M. ABENHEIMER, a former pupil of Carl Jaspers, plained that the pamphlet criticised by Dr. Brinkmann as about war guilt only, and was written to help the erman people to get some understanding of their own ilt feelings. Dr. W. FURSTENHEIM suggested that ars arise because people identify themselves with their ational idea of "truth," and such national truths may onflict. We must respect each other, and look for a nore general "truth" compatible with that of other eople.

Dr. W. C. HULSE (U.S.A.) reported that when an merican soldier breaks down under stress of war he oes so because of the conflict between what he has done nd what he has been taught is right. When a German oldier breaks down he does so because of guilt towards is officer, who is the father figure. "Have I done what e told me to do?" he asks. Dr. J. FLESCHER (Italy) iscussed the guilt reaction which comes not from what e have done but from what we would like to do; and rs. MELANIE KLEIN described how the introjected gures of the parents are built into the superego—good nd bad figures with persecutory powers. Dr. K. EBROWSKI (Poland) remarked that guilt is a regular nding in excited patients showing disintegration of the ersonality.

Collective Guilt

Miss MARGARET MEAD, PH.D., (U.S.A.) discussed not armful or pathological guilt but guilt as a sanction in society—"good" guilt which makes people behave responsibly, pay their taxes, pick up paper on the street even when no-one is looking, and refrain from throwing their banana-skins where people may slip on them. They behave in this way because they hear the voices of their parents enjoining on them the principles of good citizenship; and this sort of character training depends on the parents acting systematically as though they are better than they are—until, in fact, the child finds them out, by which time it is already too late, and their good principles have been built irretrievably into his personality. In this type of culture, built on good guilt, and found in Great Britain and the United States, the child learns to identify himself with the people in his country and with a political organisation which makes the citizen responsible for the State. In primitive cultures "guilt" character of this type is rare. Few primitive parents will work as hard as is needed to bring children up in this way, and shame is made to take the place of guilt. Instead of the parents saying "If you do that mother won't love you," or "Father will punish you," they say: "If you do that people will despise you." And as they make a habit of talking disparagingly and maliciously of the neighbours, this entails being despised by people you despise. Other societies are run on pride: the child is taught to act so that people he respects will respect him. These others are regarded as an audience and he acts as though on a stage; but a failure to acknowledge status, in such a society, is a deadly insult, and wars may be fought over a slip in etiquette. Elsewhere fear takes the place of shame or pride: any sort of unusual behaviour is thought to be alarming, and the child learns to stick to a rigid pattern in his acts. In one society no action at all is taken except under the spur of anger, and it may take a wife a whole day of loud talk to get a husband angry enough to go out and find food for the family. In some societies members are interchangeable, so that any member can be killed as a substitute for another. In Japan the solidarity of the family is carried to such lengths that every child is capable, by a false step, of disgracing his entire family and suffering rejection as an outcast. The "good" guilt type of character-structure is rare, and has only occurred once or twice in history. It makes for the most responsible behaviour, but that does not entitle those of us who have it, Dr. Mead thinks, to foist it on others. That would be a sort of psychiatric imperialism. We must fit different cultures together by other means than force.

In the general discussion, Dr. HENRY V. DICKS referred to Flugel's criteria of moral development—from the egocentric to the social, from the unconscious to the conscious, from autism to realism, from fear to security, from emotional to intellectual judgments, and so on. The triumph of the reality-ego over the superego helps to lessen unconscious guilt. Guilt is part of the natural social equipment of children, and development depends on the gradual internalisation rather than projection of guilt, and on the growth of reparation-guilt over persecutory guilt. For Western European children the introduction into the superego of "good" and "bad objects" takes place early, and it is important to know the ratio of love and hate in this ambivalence. Cultures which include a high proportion of bad objects must erect barriers for dealing with their effects. Collective guilt, in such cultures, would be a reaction to severe individual guilt. Germany before the war appeared to all observers to be more rigidly ordered than any other country and to insist more on good behaviour in children. The father figure was built up, and a high degree of conformity was required. But the picture became that of an adolescent revolt turning to the Nazi movement, with the leader as the father figure. Before the rise of Hitler, in the depression, gangs of delinquent boys were wandering the country in revolt against paternal authority. The revolt was, of course, most noteworthy when economic forces made paternal authority a failure. In fantasies of parricide the boy identifies himself with the sadistic aspect of the father, and the craving for tenderness is repressed. Now we are beginning to hear of such groups of wandering boys again in Germany protesting against the adult world which has betrayed them. It has been found by those who have tried to work with such groups that the hostility of the boys is roused if the worker refuses to fill the omnipotent father rôle. Dr. Dicks suggested that we need studies to assess the positive and negative aspects of collective guilt in maintaining world order, and the optimum balance between freedom and authority in bringing up children. We also need to know whether shame-cultures show a preponderance of introjected good or of bad objects, as compared with our own guilt-culture.

Group and Individual Therapy

Opening this discussion, Dr. C. A. MEIER (Switzerland) suggested that there are possible dangers in group psychotherapy through loss of personal contact and substitution of mass methods. Dr. W. B. TERHUNE (U.S.A.) described work on brief psychotherapy, which, he said, should be directed to getting the greatest effect in the shortest time, with the least possible suffering to the patient. The therapist needs an eclectic attitude but he must also know exactly what he wishes to achieve in each individual case. Brief psychotherapy uses abreaction to give the patient a working knowledge of his emotions; group psychotherapy, occupational therapy, and systematic aftercare are all essential.

Dr. W. R. BION described his recent experiences with group psychotherapy. He has been trying to evolve a technique in which the presence of a group is as essential for therapy as is the presence of the individual patient in individual psychotherapy. He uses the rapport between himself and the group as the basis of therapy by attempting to interpret the nature of this rapport to the group. Among the group are found attitudes of hostility, anxiety, confusion, and silence, all of which must be taken up with them. In order to handle the events in the group, Dr. Bion has hypothesised a "group mentality," which arises from each individual's struggle with his own difficulties in the group. This group mentality expresses itself through the "anonymous contributions" of each individual—i.e., the unconscious non-verbal expression of hostility and other repressed feelings. The existence of the group mentality presents a challenge to the satisfaction of each individual's personal needs; and the conflict thus aroused leads to what Dr. Bion calls the "group culture." These three elements are used in interpreting to the group what is going on. The group resists recognition of the tensions within it; and up to forty sessions are needed before they begin to understand the nature of the experience which they are undergoing. At this stage the patients begin to be aware of emotional phenomena in a new light.

Dr. DANIEL BLAIN (U.S.A.) reviewed the use of group psychotherapy in the United States. Increased experience of this form of treatment during the war has led to the conviction that it is important in its own right, and not just as a method for dealing with many patients at the same time. He described four main categories of treatment: (1) direct therapy, for the specific purpose of curing neurosis; (2) indirect therapy, for assisting other treatment (e.g., occupational therapy); (3) as an aid in the development of young people (e.g., camps); and (4) all other meetings in which individuals come together. He emphasised the importance of special training, particularly for therapists carrying out direct group psychotherapy.

In the discussion which followed, Dr. J. D. F (U.S.A.) described the use of analytic methods of therapy with neurotic and psychotic adults. Psy logists and psychiatric social workers are being used auxiliaries to the psychiatrists for research into gr methods. Mr. S. R. SLAVSON (U.S.A.) pointed out group therapy is based on the well-known principles transference, catharsis, insight, reality testing, sublimation. He emphasised the importance of sel patients with the same underlying dynamic distu Dr. RICKMAN held that group therapy is going the same phase now as did individual therapy 25 ago. The important thing is to ignore warnings of group therapy is not, and to seek to learn what therapy is. He suggested that the important feature between group and individual psychotherapy the taking up of the emotional experiences of the me particularly the relationship between patients therapist. With regard to brief psychotherapy, Rickman warned against attempts to avoid and difficulties for the patient; it is just these which have to be taken up if therapy is to succeed.

Public Health

Statistics for March Quarter

NEW low records for infant mortality, the ge death-rate, and deaths from influenza are recorde the first three months of this year by the Regi General for England and Wales.[1]

The provisional infant-mortality rate was 41 per related live births, the lowest for any first qu This is 11 below the figure for the same period a earlier, and 25 below the average for the March qua of the ten preceding years. (For the second quarte this year the provisional rate is 31, which is the lo rate for any quarter on record.)

Births totalled 202,184, representing a birth-rat 18·9 per 1000. This compares with 193,580 births a rate of 17·8 for the preceding quarter, and 21 births and a rate of 22·8 for the corresponding qu of 1947. The average birth-rate for the first quarte the five years 1942–1946 was 16·7.

The number of illegitimate births, included in total, was 11,055, or 5·5 % of the total births regist compared with 12,684, or 5·3 %, in the correspon quarter of 1947. The 5043 stillbirths registered r sented 24·3 per 1000 of the total live and still bi which was 1·3 lower than for the same period a year The stillbirth rate per 1000 total population was 0·

The number of deaths registered was 132,705, r senting a death-rate, based on the 1947 total popula of 12·4 per 1000—a new low record for any M quarter. It compares with 17·1 for the correspon quarter of 1947 and an average death-rate for the quarters of the five years 1942–46 of 14·3.

Deaths from acute poliomyelitis and polioenceph (provisional total excluding non-civilians) numbere compared with 24, 40, 429, and 196 in the four prec quarters.

SURVEY OF SICKNESS

An analysis of the latest returns of the Social Su of Sickness shows that in November, out of 2520 interviewed 1018 reported some illness or injury there were 931 consultations with doctors; ou 3138 women interviewed 2339 reported illness or in and there were 1615 consultations with doctors. Du the three months October, November, and Decem illness or injury of some kind during a month reported by 69·8 % of all persons interviewed; was an average loss of exactly one day a month each person interviewed. Among housewives illne injury was reported by 70·3 %, compared with the ger level of 69·8 %.

Reconstruction

HOSPITAL REGIONALISATION

Three Categories of Specialist?

Most medical men expect that the National Health vice will remove from their professional life many ures which they have traditionally cherished. They ve, however, promised willing coöperation, and it is refore necessary to see what new features can be oduced to counterbalance the loss of the old. A com- hensive medical service is certainly one of these, and ugh it has been promised it will need great and tained effort from the whole of the medical profession ore it can be achieved.

Hospital regionalisation affects more particularly the sultants and specialists. It has already been accom- hed on paper, but much remains to be done before hoped-for benefits can be realised. This brilliant ception, properly carried out, will raise and maintain a high level the work of hospitals throughout the ntry. Every hospital staff will have a share in the demic and more specialised branches of the profession, ich previously were almost entirely the preserves of university teaching hospitals. These in their turn l gain a wider outlook from closer contact with duates from other schools, for there is no doubt that y have often been unnecessarily isolated and narrow, gely owing to a strong tendency to "inbreeding."

The ideal, difficult in any case to attain, may be mpletely lost unless measures are taken soon. There already signs that regionalisation will prove to be ne like "balkanisation," with the teaching hospitals erting their supremacy and patronage while the ellite hospitals form uneasy and grudging alliances ainst them. The fact that the teaching hospitals ve been placed in a separate compartment from the her hospitals within the region is an important factor the situation and from this point of view unfortunate. The first signs of conflict are already appearing with formation of regional consultant committees. The ching hospitals hold that their special position entitles em to a majority on these committees, while the her hospitals prefer the more democratic method of unting of heads, since they are superior in numbers.

What is needed? First, a revolutionary change in minds of most hospital medical staffs. Every con- tant knows that while most of his colleagues are dividually broad-minded and progressive, when grouped gether as a staff they tend to be parochial, narrow, d even jealous in their attitude towards other hospitals. is change of mind will be made easier by the group area medical committees taking over some of the nctions of the hospital medical committee, which ould lead to a wider outlook and loyalty; but the odwill of consultants of eminence and sufficient rength of character to withstand the disapproval of eir colleagues will be needed.

In our opinion the interchange of consultants is obably the most important single factor making for tegration throughout the region. Opportunities of eeting and working with a wide variety of colleagues ust be beneficial. This idea has been generally approved d even occasionally realised, but its realisation has been nited for economic reasons which should no longer apply.

Categories of Specialists.—We suggest that there should three main categories of specialist: (1) group or area;) regional; and (3) national. We recognise that ter shades of distinction could be devised, but these ould probably be unnecessarily complicated and vidious. The above classification is already largely in e and should not be difficult to apply.

1. *Group specialists*, the junior grade of consultant, should be given the opportunity of attending specially arranged resident courses at the larger hospitals, where they could meet and mix with their senior colleagues. They should also be offered the chance of working for short periods in supervised posts such as registrar's or first assistant's, either when the holder of the post is on holiday or by interchange.

2. *Regional specialists.*—This should be the basic appointment, and its holders should be men of sufficient standing in their specialty to be acceptable to every hospital in their region. Each group should have a number of regional specialists so that interchange within the region would be possible for all groups.

3. *National specialists* should be men of the highest clinical standing, acceptable to all regions throughout the country.

These categories of specialists might well be closely related to the awards recommended by the Spens Committee for outstanding ability. This part of the committee's report is the most controversial, though it is recognised that the encouragement of clinical ability is most desirable. Many people fear that the Spens awards to a third of the profession in consultant practice will to a large extent be confined to the big centres. In our scheme the awards would be widely scattered, and would do much to encourage and improve the skill available *at the peripheral hospitals.*

Method of Selection of Specialists.—In the first place men would be chosen in the various categories for their qualifications and experience, but later the regional specialists should have a large voice in the election to their ranks, for they would rapidly acquire a first-hand knowledge of the talent available. Their experience of the region would be such that they should have a large representation on all regional medical committees and this would do much to diminish any possible conflict between the teaching and other hospitals on this point.

If any group had not sufficient men of the regional status it should be possible to attract such men by the offer of the appropriate Spens award when making the appointment to the group. There might also be a lack of suitable specialists throughout a region and this could be adjusted in a similar manner. Occasionally a group might not offer enough scope for regional specialists and regrouping might be necessary.

Period and Method of Interchange.—We suggest that a minimum period of six weeks in every two years should serve as a basis for the interchange of specialists. A shorter period might be too short for any useful work or contacts and a longer one might sometimes cause difficulties. Some time before each period of interchange lists could be made, and a proportion of the interchanges, say 30–50%, should be made by drawing lots. Everyone should be subject to this, but after the required number had been drawn the remainder might be by arrangement. In these cases the minimum period of six weeks might sometimes be increased with advantage. The rarer specialties would of course need different treatment.

Advantages.—Such a scheme might do much to integrate and raise the level of service throughout the country. It would in no way impose restriction on the clinical work of recognised specialists and would enable their ability to be assessed by their colleagues at first hand and not only through their writings or other methods of publicity. The Spens awards would produce some benefit to the profession as well as to the individual, and would go to men who deserved them for their clinical ability, since new work or special skill would quickly bring invitations or nominations from other hospitals or regions. The awards would cease or be reduced as anyone became less acceptable or lost the desire for interchange. In our opinion this is as it should be, unless the awards are to become more like pensions than recognitions of particular professional competence.

Disabilities

11. ILEOSTOMY

PERHAPS I was lucky, but it did not take me long to get used to having an ileostomy. The operation was done when I was $17^{1}/_{2}$. At first I was too ill to take much interest in anything, and then, while getting strong again, I found that the novelty of the experience usually kept my spirits up. But there were occasional fits of utter depression, some of them, I must admit, deliberately brought on, probably to stir up sympathy. Later on, when I began to find that life was not to be nearly so curtailed as I had feared, the attacks of depression became less common, and now they are rare.

Some $3^{1}/_{2}$ months after the operation I was able to get about for at least $2^{1}/_{2}$ hours between one evacuation of the bowel and the next. At first it was hard to do this without using a catheter, but through a deliberate attempt to lengthen the interval the muscles eventually started to work properly, and I dispensed with the tube. Now, to secure evacuation, I sit down and gently massage the lower abdomen; and by tensing the muscles at the right moment—a trick soon picked up—I can discharge $^{1}/_{2}$–$^{3}/_{4}$ of a tumblerful at a time. If there is any difficulty through retained flatus, it can often be overcome by changing the position of the body—for example, by resting on one arm or lying on the back. When, after several minutes, nothing has happened, a good remedy is to replace the appliance and walk round the house for a while. At each sitting, which lasts about half an hour, I aim to get rid of a pint or more, but the amount varies with the intake of food and drink. It pays not to hurry over the job; otherwise one may be compelled to come home halfway through a picture or a dance.

This procedure is carried out four times a day—after breakfast, lunch, and tea, and before going to bed. By sticking to this time-table I can nearly always be sure that nothing disastrous will happen between times. When I wish to stay out longer than $2^{1}/_{2}$–3 hours, I am careful to finish my last meal at least 3 hours before leaving; in this way I can usually manage to stay away for up to 5 hours without any attention to the ileostomy. While not on a strict diet, I avoid certain foods, such as nuts and very highly seasoned dishes. When going out I do not take such foods as onions, herrings, peas, and beans, because of the smell or the flatulence which they cause; and I steer clear of most vegetables and of raw apples as they often take some "getting rid of."

I do my dressings in a separate room with a small table and a double-seated occasional chair; the only special piece of furniture is a cupboard. There is one round and one kidney-shaped enamel bowl, the first for excreta and the second for soiled dressings, which are later burnt in the closed kitchen stove. Between dressings everything is stored in the cupboard; this I try to keep as tightly closed as possible, for flies can be a nuisance, and when there are any about I spray the room with D.D.T. after each dressing.

Dressings take about 1 lb. of cotton-wool a week; and the cheaper varieties seem to be more absorbent than the more expensive. Sometimes I also use cellulose wadding, which is cheaper still. The skin around the ileostomy is usually kept healthy with zinc and castor-oil ointment; but if it does become inflamed the addition of some 'Dettol' ointment soon puts things to rights. To keep down the smell of any excreta which flow into the box between dressings, I put into it $1^{1}/_{2}$ dessertspoonfuls of powdered wood charcoal; this also thickens the excreta, thus preventing leakage.

For the actual dressing I first clean the skin with cellulose wadding, and then smear the ointment round the ileostomy over an area a little larger than that covered by the appliance. Over the ileostomy I place a piece of gauze with a hole in the middle, then a s shaped piece of cotton-wool. Next comes the and round the rim of the hole in it I also smear oint as a seal against the cotton-wool. Strips of cotton are applied round the bottom of the box and the nearest the hole; these are held in place by the s of the belt and a piece of 2 in. bandage looped at end and passed over the buckles of the belt and r the bottom of the box. This is rather a primitive ment, but it saves a lot of cotton-wool. This surro cotton-wool can be dispensed with if the box fits well; several times I have tried to do without cotton-wool round the ileostomy itself, but th friction the skin soon becomes sore, especially i box does not fit well. At the top of the daytime are three air-holes. At first, when I stooped for with the box partly filled, some of the contents w leak through these holes. To prevent this, I place the top a piece of cellulose wadding about 3 in. and long enough to be held in place by the straps o belt.

When going out for longer than 5 hours or so, I a satchel or small suitcase containing cotton- cellulose wadding, gauze cut to shape, a small bott charcoal powder, and another of zinc and cast ointment. It may be necessary to take a tin or receptacle for soiled dressings; and if this is use should be sprinkled with dettol to reduce the cham smell. With experience all these things can be pa into quite a small space.

The last dressing of the day is slightly different f the rest. I smear with ointment a patch of skin the size of the night box. and then apply g cotton-wool. The holes of this box I cover with a strip of cotton-wool, with one end held in place by belt and the other tucked under the edge of the As this piece is liable to become damp in the ni cellulose is unsatisfactory as a substitute. The ileost being on the right side, I always sleep on the left, the rubber bag of the night box across the body, so there is less chance of the appliance leaking. My pyj get slightly soiled about once or twice a week, real "disaster" necessitating clean sheets takes only about once a fortnight. Unfortunately, when laid up in bed with a cold the time-table soon astray, and control is lost; but this is quickly rig as soon as I get up and about again. Lately I w bed for some days after undergoing an operation on kidney. The ileostomy worked wonderfully by itsel

* * *

I am extremely lucky to have youth on my I was fortunate, too, in not having previously got se into a job, which I might have had to give up readjustment has been less troublesome than it m have been. I have been able to find work which I do at home and which enables me to stick to the t table. If I get on well, I should be able to earn en to get married and to make a home of my own; having no-one but myself to see that I get on wit I have to urge myself to keep going, and I find all of excuses for laziness.

Naturally, I like a certain amount of female comp and, being shy and rather easily embarrassed, my bility has been the biggest hindrance here. To ca friends, of course, I don't mention it, but a girl finds out that I have been ill. One of the first quest seems to be "What is your job?"; this is followe "Where do you work?" and when I reply "At hor they invariably ask why. To casual friends I thin is enough to say that I have been ill, for this is l likely to embarrass each party. Girls, and for matter all my friends, have always been extrer understanding, rarely embarrassing me with expres of sympathy.

Often I baulk at making an arrangement in advance, n case, I suppose, anything should happen physically o prevent me carrying it out. Yet only about three or four times in 3 years has anything actually stopped me from fulfilling an engagement or made me hurry home in the middle of it. When I have to refuse an invitation to anything lasting more than 5 hours, my hief feeling is one of annoyance rather than of misery, and even this lasts only a few minutes. There are plenty of things I can do, including tennis, swimming, skating, ycling, driving a car—in fact, anything not too strenuous or long continued. In my rare fits of depression, I soon ealise that I can do more than many people who have been as ill as myself.

Obituary

JOSEPH CUNNING

M.B. MELB., F.R.C.S., F.R.A.C.S.

Mr. Joseph Cunning, formerly senior surgeon to the Royal Free Hospital, died at Reigate on July 29 at the age of 76.

Mr. Cunning was born in Australia, the son of James Erskine Cunning of Victoria, and he was educated at Ballarat and at Melbourne, where he graduated M.B. in 1894 with honours in medicine and surgery. He held house-appointments at Melbourne Hospital before coming to this country, where, after postgraduate study at St. Bartholomew's Hospital, he took his F.R.C.S. in 1901. In the same year he was appointed resident medical officer to the Royal Free Hospital, where four years later he joined the honorary staff. He was also a member of the staffs of the Victoria Hospital for Children and of the (then) Cancer Hospital.

Cunning kept up his ties with his native land, serving as president of the Australian and New Zealand Association of Medical Men in England, and in 1932 he was elected to the fellowship of the Royal Australasian College of Surgeons. He retired from the staff of the Royal Free in 1931 after an association with the hospital lasting thirty years. "During his 26 years on the active staff," writes L. E. C. N., "Cunning proved his worth as a surgeon of outstanding ability, especially in the field of abdominal surgery. His technique as an operator was superb, coupled with extreme gentleness in handling the tissues. He never appeared to hurry, but he wasted no time. His colleagues can testify to his skill and craftsmanship, and it was a pleasure and privilege to see him operate. He always had his patients' interests and welfare at heart, as witnessed by his kindly approach and readiness to listen to their story. A versatile teacher, Cunning had the power of imparting knowledge, and many students and residents have cause to recall with gratitude his inspiring ward rounds and clinics."

Mr. Cunning married Dr. Annie Thin, a student of the London School of Medicine for Women and a former director of the open-air school in Regent's Park. They had two sons and a daughter.

"...'Facts, and more facts!' cry the laboratory scientists, banging their fists with approval on the bench, and jolting some apparatus in course of construction. 'But what's their significance?' say the natural philosophers, looking up from their desks, leaving the mixture of doodles and speculations scribbled on the paper before them. And the two groups eye one another with suspicion and mistrust. Which camp you work in is a matter of temperament, and the sad truth is that so few are capable of work in both. Yet both are essential to the progress of science."—Dr. J. L. CRAMMER, *Science News*, 1948, 8, 7.

In England Now

A Running Commentary by Peripatetic Correspondents

IN the 8 months since they arrived in New Zealand 12 out of 24 girls given free passages as pupil nurses have left their hospital, and it has dawned on the authorities that they only came to the job for the sake of the free trip. But why else? If it was the training they wanted they could have got it at home. And now the old question is being asked, why do immigrants want to go home? Some say that the trouble here is that the government should not have imported spinsters in the same ship as a number of bachelors. Which is pretty obvious, but doesn't matter because the Dominion is the gainer anyway. But the Blimps with their old what's-happened-to-the-pioneering-spirit lament are back on their perch, and find plenty of cases to support their argument in men who should have been able to make a good thing of life in this country and didn't. But the pioneers did not have to wait four months for a land court to confirm their purchase of a holding, and they didn't have to pay sales tax on the planks milled from the trees they had felled themselves. Besides, I suspect that this adulation of the pioneers is a bit overdone. Life in England in the hungry '40s must have been so unpleasant that the back-blocks could hardly have been worse; and once they had rounded the Horn they were not likely to want to do it again. I bet they were just as homesick as we are, only the reaction is different. Some of us just go home. They had home sent to themselves. Unfortunately home meant gorse and sparrows; but though they have plenty to say about gorse and sparrows on other occasions the Blimps are apt to forget them in this particular discussion.

This business of adapting the immigrant to his new country is worthy of more attention than it has yet received. The Americans, as usual, did the thing thoroughly when they occupied England. Each soldier was given a booklet which explained the strange features of the country he was going to, films were shown and lectures given. The British Army did the same sort of thing for returned P.O.W.S. But the prospective settler has to find things out for himself, and it is scarcely to be wondered at if he sometimes comes down to his new earth with something of a bump. In my own case the only introduction was a spontaneously arranged "quiz" on board a few days from our destination, when the natives answered some of the immigrants' questions: and then it was too late to think again. Housing? It's tough. Clothes? All right for most things, but shirts are tough. Cars? They're tough. One came away convinced that most things were tough except the meat. An introductory course for intending emigrants a week or two before the boat sails is the answer, if there is one.

* * *

How often must we have pictured just what we should do if we found ourselves in a completely non-austerity world. But should we really react by massive purchases, or is it just I who am a bit slow off the mark? I remember the first shop window display of hot-water bottles I had seen in England for years. "Good" I said to myself "We'll be able to get H.W.B.S again," and I left it at that and went home and told my wife. And when I went back to the shop the next day the H.W.B.S had all gone. It was three months later, in a town a hundred miles away, that I next saw one—and bought it.

I have lived in a land of milk and honey for eight months now, but my reluctance to buy anything remains as fixed as ever. I still can't bring myself to ask for more than would be thought a reasonable quantity for an Englishman on 1947 standards. "May I have a 5 lb. tin of honey, please?" One. I feel I could do with half a dozen. But what is even worse is going into a shop where I am not known. I expect to get a stony look and the usual remark about regular customers; but no, the shopkeeper actually wants to sell you something, and he doesn't care whether he has ever seen you before or not. I confessed these inhibitions to my wife and I was rather surprised when she said she experienced them herself. "I look at the dresses and the children's clothes" she said, "and I think 'that's just what Joan was looking for' or 'that would be the very thing for Mary,' but I can't do anything about it, and I don't seem to want to go in and get things for myself."

For ten years we have been pressed deeper and ever deeper into the mould of restricted domestic planning, and even if food returned in Beetonian quantities we should find it difficult not to make up our menus on two-pennyworth of corned beef. Fill the shops with unrationed consumer goods, and the public would goggle for a few hours at the piles of sheets and soap and tinned fish, and then they would turn back with relief to invest their money in the dogs or blue it on twopenny cigarettes (after all something would still have to be taxed). There may be fallacies about this economic utopia, but there's no doubt about the effects of prolonged restriction. I can fully understand now how it is that the greengrocer is back at the onion basket the day after he wins £30,000 at the pools. He just can't help it.

* * *

Out here in our West Indian colony we decided to buy a few hens, just enough to keep the household in eggs. The hospital's East Indian milkman was able to oblige, so I asked him to bring along three Rhode Island hens as a start. He looked shocked and lowered his eyes. "But mistress, you must get a cock also." I was new to the game, and unwilling to precipitate an argument on the sex life of hens; but something told me Mr. Lal was wrong. However, the servants supported him; so along came the hens accompanied by the cock, a fine young fellow with a burnished green tail and a prodigious appetite. The hens laid as disappointingly as hens always do, but we did get a small regular supply. In due course one of the senior members of the staff came to hear of the cock's existence. "Stuff and nonsense," he snorted, "quite unnecessary, kill the creature!" So, feeling a little bewildered, we killed and ate him, finding him by this time a little tough. There was consternation in the kitchen. Ambrosine wept at the prospect of no more eggs, and Nannie invoked the deity. "Mistress," she cried, "this do be flying in de face of de Lawd, who did order dat de animals go in two by two! Who are we to deprive de hens of dere rights and to risk our own salvation wid de Lawd?" Oddly enough, the next day there were no eggs, nor the day after, nor the day after that. Mr. Lal and the servants were triumphant; but I stuck rather shakily to my ground, and after exhaustive inquiries among my hen-keeping friends discovered that the cock's sudden end had coincided with the off season for eggs, and that *no-one* was getting any. I pointed this out to the servants, but they knew better. Time passed, and in due course our sex-starved hens began to produce bigger and better eggs than ever before. I had the good taste not to draw attention to this in the kitchen, but to slip the eggs into the fridge when the kitchen was empty.

* * *

How does the miller come by his golden thumb? I liked my fellow peripatetic's version (July 24), though it does not tally with folklore. "Miller's thumb" is a pleasantry very much akin to "Purgatory pickpurse." "Golden," from keeping it on his side of the scales when weighing, or so our proverbs have it. By their dozen they poke fun at this occupational trauma, as for instance: "It is good to be sure, quoth the miller, when he moultered (took the toll) twice." Chaucer, in the quotation given, goes one better than that, adding "yet" (=once again) and the terminal oath for good measure.

* * *

The instructor hit him three times on the head with a poker to demonstrate to a group of industrial medical officers that safety hats effectively protect the miner against head injury. Alas, the unfortunate tyro had not adjusted the inner lining of his hat; so its crown rested on his thin aristocratic cranium. He blinked at the first blow, swayed at the second, and paled visibly at the final stroke. Any way, these medical officers will never forget that the safety hat protects only if it is worn properly.

Letters to the Editor

THE PATIENT AT HOME

SIR,—Your leading article last week admirably described the plight of the doctor who would serve in the new scheme to the limit of his capacity and who is popular enough to attract the maximum of 4000 patients. Unless he can afford an assistant he may well be dissatisfied with his prospects, for medicine must now seem to him an endless succession of packed surgeries.

Few doctors would gladly undertake to work under such unfavourable conditions, and if they did they would not be running a health service. A surgery full of people who have come to be patched up after a fashion strikes me as a good example of what one might call a disease service—not unlike witchcraft, if one considers that the doctor must help some 30 people an hour without knowing anything about them beyond the part selected for show by the patient. Surely the medical mind is not so disease-ridden that it will accept this as the proper way to care for the nation?

If we are to use the new scheme as it is meant to be used we must aim at reinstating the family doctor—in full strength and with a will to practise health. This means shifting the interest from the casual visitor in surgery to the patient and his family at home. It takes time, and it could be done, as you suggest, by reducing the present maximum to 2000 on a higher capitation fee; but it could also be done by giving doctors with full lists paid assistants. By this expedient, similar to the scheme advocated in the first Spen's Report, newly qualified men would be given excellent training opportunities, while doctors who have proved their worth to the public would be able to widen rather than restrict their sphere of influence. The good family doctor has qualities which cannot be exploited in the treatment of warts or ingrowing toe-nails; he is a specialist in handling human beings, and he will be most useful when he can handle as many as possible in his own way. He is altogether too valuable a member of the community to be wasted, and it seems a pity to cut down his list instead of giving him better opportunities to use his particular gifts. Love of work, among other things, makes him what he is; but will it survive the crowded surgeries which pressure of circumstances threatens to force on him? We may assume that he will put up a fight against circumstances, and you are right in asking that he should be helped. The family doctor you describe is the family doctor we want; but the position which he should occupy in a household can never be achieved through contacts in surgery. Patients who hesitate to avail themselves of the N.H.S. because it would mean attending surgeries show that they appreciate this.

These patients may not know precisely what they would miss, but it is something they value pretty highly and something that should be available to them. It is not the professional skill of a medical man, but the influence on the family as a whole of someone who knows them well enough to identify himself with their interests and to guide them accordingly. The patients know, and the doctor knows, that he can learn more about a family in one visit than in months of attendances at surgery; they only need to be assured of his interest in them to give him all the confidence he needs; but it is hard to show the right kind of interest during a short consultation in surgery. It is extremely easy to enlist the coöperation of a household during a leisurely visit, and the doctor who combines this with his knowledge and the patients' trust becomes a social institution of the first importance. He can be the trained ally of common sense and right thinking in all matters pertaining to family life and welfare, and an educative force in a sphere all his own. The more he knows of his patients, the more inclined they are to trust him and to be guided by him—indeed, they ask for nothing better. Once he does occupy this position in a household, he is the tower of strength, the guardian of health, the hope of the stricken, and a whole lot else.

What is less obvious (although you mention it) is that he is also the person who can make the specialist's service really useful to the patient. The specialist is no more inclined to cast a decisive vote on the evidence of a single examination than th[illegible]ht to be; no is he inclined to exert himself in a case where he is not particularly needed. The family doctor is supremely well qualified to know when and where a specialist's services will be most useful, and he is the only person who can provide the information which the specialist will need if he is to give a worth-while opinion.

But the whole machinery breaks down (or rather. fails to come into being) if the doctor's attitude is that of withholding himself from his patients, shunning contacts unless they are actually thrust on him, and generally leaving the patient in a position where he has to do all the asking. Nobody can feel cared-for under such conditions, and the asking goes on, to the discomfort of both doctor and patient. One can do more good by saying " I'd like to come and see you "—even if it is only to hand over the 4-weekly disablement certificate—than one can with gallons of mixtures; and if one happens to mean what one says, one is also a much happier person. The patient will immediately reply " Oh, please don't bother, doctor," will be overjoyed if the doctor takes no notice of this, and will be a pleasure to treat ever after. Such patients do not call one out in the night without very good reason, nor do they trouble one with requests for bottles. The doctor who "suffers" from his patients has only himself to thank for it, and I am afraid he is going to suffer horribly if he allows restrictions and conditions to be imposed on anyone who wants to consult him—particularly with private patients who remember him as all eagerness to help.

An enormous proportion of " illnesses " are the expression of some form of maladjustment or misery. The doctor cannot reckon to know anything about them until he knows the patient's background, and he should take the first opportunity to study this, once aware that trouble is afoot.

Many people take up general practice because nowhere else can similar opportunities for coöperative effort be found, and nowhere else can the good doctor be so useful to the community. His chief usefulness does not lie in his ability to diagnose and treat disease; people are not unhappy because they are ill: on the contrary, they relax; they accept the full status of invalid with some relief because their claim to the care and attention which they needed all along has at last been established without wounding their amour-propre. The people who are less happy are the patient's relatives, and they welcome help and support all the more for not having a proper claim to them.

Least happy of all are the people who can find absolutely no excuse or reason for feeling as wretched as they do; they turn up hopefully in the surgery with a " heart " and go away dejected, having been told that air-swallowing has given them a wholly pointless discomfort and that they are perfectly fit for work. They should not be allowed to remain dejected, and they can be helped—not indeed by bolstering up their hopes that the heart may yet give out and entitle them to a little more consideration, but by being allowed to talk and to enlist the friendly understanding of at least one person. Their chief trouble is that no-one ever has listened to them, and this tends to make them aggressive as well as despairing. They do not approach the doctor as a friend, they have ceased to expect friendship; they hope for a magician who will unearth the mysterious trouble and apply the correct remedy—preferably by a complicated form of treatment with an even more complicated name. These are the people who throng the surgeries, ever hopeful that the bottle will do its stuff in the end, or that the doctor will come to understand " my case " well enough to suggest something more helpful. The exact symptoms are a matter of chance, and are recorded out of politeness; one knows that if the headache is cured something else will be the bother next time. One's job is to get at the source of this nagging desire for attention and magic formulæ, and a good way of doing it is to find out what the patient is running away from in coming to the surgery. The answer is in the patient's home and in the patient's past. If one gets to know the home and the past, one can begin to see how oneself might respond in the patient's circumstances; a few pointers as to the personality should help to complete the picture and present patient and symptoms as the perfectly credible result of his or her environment (which, incidentally, is often quite incredible).

If this seems an awful lot of trouble to a doubtful end, let it be said that the patient will have begun to benefit by the attention from the moment one showed oneself ready to listen, and that his or her family will have benefited equally. An unhappy member is usually a great trial to the family and unhappiness is apt to spread. The doctor will have benefited in a number of ways, one of them being the satisfaction of having given genuine help to a genuine case, instead of placebos to imaginary ailments—which I think is what makes doctors so dissatisfied with their eternal prescription-writing in surgery.

Bagshot. S. GRAHAM.

APPARENT ACUTE GLOMERULONEPHRITIS WITHOUT ALBUMINURIA

SIR,—There seems no reason to doubt the diagnosis in the interesting case reported by Dr. Crofton and Dr. Truelove in your issue of July 10, though there must remain a little uncertainty about the complete absence of albuminuria throughout the course of what was evidently a fairly severe attack of acute glomerulonephritis. Slight and transient albuminuria is notoriously elusive even when sought " at least once daily." For this reason I would venture to suggest that the case might have been more appropriately called " acute glomerulonephritis apparently without albuminuria." Even so the author's paper is a valuable contribution to the literature on the subject.

Unequivocal examples of analbuminuric glomerulonephritis have rarely been reported, as the authors note. I cannot recall having met with an undoubted instance myself, though on a number of occasions I have seen patients suffering from marked and unmistakable signs of acute glomerulonephritis in whom albuminuria was minimal or transient throughout, and I have three such under observation at present.

The pre-albuminuric stage of glomerulonephritis, on the other hand, is not so rarely encountered if carefully looked for in the interval between the causal infection and frank signs of renal disease. It has been most often recorded in postscarlatinal nephritis, probably because the latent interval referred to is most easily observed in this disease.

Any or all of the major signs and symptoms of acute glomerulonephritis—i.e., hypertension, œdema, azotæmia, and microscopic hæmaturia—may precede albuminuria by some days. To the references in the literature on pre-albuminuric signs of glomerulonephritis quoted by the authors might be added a paper by Brasiello,[1] who mentions hypertension, hyperchloræmia, and azotæmia as preceding albuminuria in postscarlatinal nephritis.

Less conspicuous pre-albuminuric signs that have been reported in postscarlatinal nephritis are an increase in the usual leucocytosis in scarlet fever,[2] and disappearance of the alkaline tide.[3] Of pre-albuminuric signs of acute glomerulonephritis, œdema, as apparently in the authors' case (puffiness of the eyes noted, significantly, sixteen days after a sore throat), would seem to be the most common, its appearance and degree being to some extent determined by the constitution and previous habits of the patient. For example, it was found [4] that dropsy was recorded as the presenting or most conspicuous symptom in 67%, and hæmaturia without marked œdema in 16·5% of all cases of acute nephritis admitted to Guy's Hospital in 1887–88. Forty years later, in 1927–28, the corresponding figures were 24% and 40%.

Hawes and Vardy [5] comment upon the prevalence of " nephrosis " and nephrotic nephritis in China, and I am informed that in some parts of India glomerulonephritis in the form of " the large white man with the large white kidney " is still more often seen than it now is in this country.

Barlow,[6] Goodhart,[7] and Taylor [8] all refer to œdema as the most characteristic and marked feature of

scarlatinal nephritis, though it is now a comparatively rare manifestation of the disease in western countries. A hundred years ago, indeed, the terms scarlatinal dropsy and scarlatinal nephritis were used synonymously. Sometimes there was no albuminuria, at other times the dropsy preceded, accompanied, or followed albuminuria in a most puzzling manner[9] reminiscent of the kriegsœdema during 1914-18; Dr. Hahn referred to this in your issue of July 17.

The time of appearance and degree of œdema as a symptom of acute glomerulonephritis would therefore seem to be in part related to the nutritional state of the patient and the community in which the disease occurs, though doubtless it is more marked when albuminuria is excessive and prolonged. Incidentally, œdema not infrequently precedes albuminuria in another renal disorder—pre-eclampsia. It would then seem to be more obviously an exaggeration of a pre-existing state of waterlogging that normally occurs in pregnancy.[10]

M.R.C.P. EXAMINATION

SIR,—The letter of Aug. 7 from "M.R.C.P." is very timely, for never has the subject of the Membership examination been so commonly discussed. Before the war only a fortunate few aspired to become specialists and consultants; but now that the average entry is 600, and the trend towards specialisation in every branch has increased immeasurably, the whole subject of "specialist" examinations has become one of the utmost importance to a large proportion of the younger part of the profession.

"M.R.C.P." rightly emphasises that in an examination designed to test clinical ability the hazardous factor known as "luck" should be minimised by every means available. I do not think the most hardened examiner would deny that this factor is a very prominent one, especially when the whole bedside approach of the candidate has to be assessed on the results of one "long" and one "short" case. A well-known ex-censor is reported to have said that he could as easily fail a candidate on a straightforward mitral stenosis as on the most obscure neurological disorder. This can be readily understood; but a candidate who has made a diagnosis with ease and assurance on a case which he has diagnosed from the ward door can stand up to an examiner's questioning with confidence and courage: whereas another, at the next bed, faced with an uncoöperative and often misleading patient, and little wiser at the end of half an hour, is psychologically in no condition to handle a possibly truculent and browbeating examiner.

The only fair method would be to increase the number of cases and length of time allocated to the clinical portion, to read *always* what the candidate has written in the papers, and to allow him to proceed on an aggregate of marks. The numbers taking the examination at present may preclude such a lengthy test, but by no means other than the institution of a primary examination could they be thinned out. Possibly the writing of a clinical report and of a three-hour essay might act as a deterrent to all those who take the examination "on spec," and there are many such.

Other aspects of the unfairness of the examination as at present constituted spring immediately to mind. Are not many who consistently fail acknowledged to be better men than those who pass? And how many now eminent physicians had multiple attempts? How many acknowledge that they were no better when they finally passed than at their first attempt! One concludes therefore that there is about this examination considerably more than the usual element of luck.

Another point which comes to mind is the question of the significance of the examination. Is it merely to be an index of fitness to undergo specialist training, or is it rather an attestation that the candidate has completed such a course and is fit to undertake the responsibilities of specialist practice? There is far from uniform opinion on this matter. It would appear that ideally no-one should be allowed to present themselves until they have completed a lengthy period of resident appointments at recognised hospitals. The Royal College of Surgeons demands such a period (but even that is far too short), and the Royal College of Physicians would do well to consider whether a minimal period of, say, three years (or possibly even five) might not be demanded from an aspirant to its membership. The Americans, unhampered by centuries of tradition, have succeeded in laying down along these lines regulations for their specialist boards which appear to ensure a far more *rigid* selection of suitable men and women, and a far better training of those selected.

It is only by this means that the title of M.R.C.P. can possibly have any value as a designation of real specialist status; and thus only will it cease to be merely a key to admission to certain house-appointments, registrarships, and the like.

WOULD-BE-MEMBER.

SIR,—"M.R.C.P." says that the clinical examination should be preceded by "stiff papers" for the purpose of weeding out the weaker candidates. Surely it is the aim of the censors' board to admit to the membership only those with *an accurate and reliable clinical* knowledge; and, as everyone knows, those who write the best papers are not necessarily the best doctors. If there were several searching clinical examinations, perhaps "M.R.C.P.'s" plea for fairness would be satisfied.

Aberdeen. ELMA M. SIMPSON.

VITAMIN E IN COLLAGENOSES

SIR,—I was interested to read Dr. Burgess's article (Aug. 7) in which he referred to his success in treating fixed types of lupus erythematosus with mixed tocopherols (vitamin-E complex), the more so as his results seem to have been so very much happier than ours have been at St. Thomas's Hospital.

Last November, Dr. G. B. Dowling asked me to investigate the effect of vitamin E in lupus erythematosus, and I began to treat a series of such cases with synthetic α-tocopherol, beginning with a dose of 100 mg. daily and working up, in the absence of any favourable response, to a maximum of 300 mg. daily. Synthetic α-tocopherol was chosen as the only form of vitamin E available in this country in sufficient quantity and concentration to be practical for such a trial.

Altogether 22 cases were treated, all for at least ten weeks and 16 for more than four months. They were mostly cases of many years' standing, 11 having been going on for more than ten years, 5 for between five and ten years, and only 1 for less than two years. All except 4 had previously been treated unsuccessfully with one or more of the common gold, bismuth, or arsenic compounds; and all were thoroughly examined for any other evidence of disease, and seemed otherwise perfectly fit. Several had had real or suspected septic foci dealt with in the past, and 6 had, at some time in the course of their affliction, cleared completely, only to relapse later. The α-tocopherol was given by mouth, and no patient was considered to have failed to respond unless he had received not less than 200 mg. daily for two months; most cases had 250–300 mg. for a longer period. No single case cleared, or even improved dramatically, under the treatment; 4 showed some slight improvement, 11 remained quite unchanged, and 7 became worse in that their lesions became more extensive or new lesions appeared while the patient was taking the α-tocopherol. Of these 7, 1 was at first thought to be showing definite improvement. We had no controls, but at this point I should mention the case of a patient who was referred back to her own doctor with the suggestion that she should be given vitamin E. Six weeks later she returned to us with every trace of her lupus erythematosus gone, but, alas, the letter she brought with her informed us that her doctor had been unable to obtain any vitamin E, and so had continued treating her with calamine lotion as before.

As a result of this trial, we came to the conclusion that α-tocopherol was without value in the treatment of lupus erythematosus. Furthermore, this trial was begun in the late autumn and carried on throughout the winter and early spring, a time of year when a number of cases of lupus erythematosus show spontaneous improvement

---

[10] Osman, A. A., Close, H. G. *Quart. J. Med.* 1930, 23, 393. Dexter, L., Weiss, S. Pre-eclamptic and Eclamptic Toxæmia of Pregnancy. Boston, 1941; p. 20.

It will be interesting to see the more detailed report[1] on this work, to which Burgess referred; but should this be confirmed it will be apparent, in the light of the trial that I have briefly described, that the part of the vitamin-E complex responsible for its good effect in fixed types of lupus erythematosus must be some other than the α-tocopherol, unless of course the synthetic product differs in some subtle way from that occurring in nature. At first sight our doses appear rather smaller than Burgess's, but he does not state the percentages of the various individual tocopherols in his "mixture," and even if half were made up of the α-tocopherol, it will be seen that, as we gave this in its pure state, our doses in terms of the α component were more than equal to his. Therefore, had this substance been an active therapeutic agent in lupus erythematosus, our results would have paralleled those of Burgess, instead of proving a sorry failure.

R. D. SWEET
Assistant, Skin Department.

BEDS FOR PULMONARY TUBERCULOSIS

SIR,—I should like to endorse the excellent points made by Dr. Tattersall in your issue of Aug. 7 and to add a few remarks of my own.

The choice of cases for the few beds available to the chest physician is a difficult and responsible task, but I have no hesitation in giving preference to the young case in the early treatable stages. To fill these beds with chronic or more advanced cases of doubtful treatability for months on end while the same bed could be used to accommodate, in succession, a number of young persons with early disease, seems to me both illogical and inhuman. The plea that the more advanced case is more infectious and should therefore be isolated is short-sighted. With waiting-lists of six to nine months many of the early cases, thus debarred early admission and rapid sputum conversion, will be equally infectious (and probably more mobile) before they are admitted.

The continued progress of surgical technique is offering more and more of the advanced cases major collapse therapy, with the inevitable result that the average length of stay in sanatoria is steadily rising just at a time when the mortality from pulmonary tuberculosis is also on the upgrade. It is perhaps partly due to this trend in surgery that the death-rate from tubercle is rising, for while sanatorium beds are thus blocked with "doubtful risks" those awaiting admission are steadily advancing to become hopeless cases.

The time has come when very serious consideration should be given to the bed situation for tuberculous patients. The reason so often given for the present position is the shortage of nurses, but I feel that there is now a danger of this becoming a facile excuse for inaction. It has already been suggested by Dr. Bentley[2] that much can be done to relieve the position by reorientating our views on tuberculous nursing without seriously affecting our standards of treatment.

It is far more important, in my view, to review the whole tuberculosis problem in the light of its importance to the community as the disease which kills more of our young, productively useful citizens than any other single factor. This disease should be tackled with priority on a nation-wide scale. We find, however, that it is far easier to admit to hospital the patient with acute pneumonia (whose illness can be reduced with sulphamerazine to a three-day fever), or the one with cardiac failure (whose essential treatment is rest), or carcinoma (who has retired from useful life) than ever it is to obtain urgent adhesion section or phrenic crush for the young girl of 19 years with very early cavitating tubercle and the most productive years of life before her. The obvious answer is the immediate reallocation of existing beds on a basis commensurate with the importance of the diseases they are to serve. The available nursing power would thus be fairly and most usefully employed. The nationalisation of hospitals has made this practicable.

In fact, however, there are signs that the new scheme may worsen the position. The keeping of a central waiting-list for sanatoria—the common practice of health authorities—has always been cumbersome illogical when dealing with disease. Admission shoul be determined by chronological order of diagnosis by clinical and social urgency. The only person knows all the facts is the chest physician in charge c case and it is he, therefore, who should determine order of admission of his cases and not a purely ad strative officer at a central office. Under the new reg boards the central waiting-lists are even longer more cumbersome and remote from the patient, f most instances a number of health authorities fall w one region.

Apart from the reallocation of beds, what ther we to do in the present impasse? Decentralis of the waiting-list with allocation of certain beds to clinic would greatly ease the situation. The physician of the area could then keep his own wai list and arrange admission according to the urg As Dr. Tattersall remarks, close collaboration bet chest physician and superintendent is necessary, it should be much easier under these circumstances no central authority intervening.

An even more satisfactory scheme would be fo chest-clinic staff to take direct charge of the maj of beds for the area so that continuity of treatment a satisfactory integration of domiciliary, short- hospital, and long-term sanatorium treatment attained. Many cases that are now kept in sanato for an unnecessarily long time would certainly not if the physician concerned were also responsible fo waiting-list.

Finally, I would point out that in general far too is done for urgent cases while they are waiting m for sanatorium admission. If more collapse the were undertaken in the patient's own home, with the few beds available in the local hospital used fo associated adhesion section and phrenic-crush o tions, many patients would eventually not need torium admission or at least their stay woul shortened. I am certain that we need many more trained and qualified men to undertake such wo chest clinics. The status of the tuberculosis office long unsatisfactory, should be raised; he shoul offered a specialist salary and provided with beds. then will the work attract men of specialist status an attack on tubercle begin to be really successful.

Hammersmith Chest Clinic,
Postgraduate Medical School of London.

PETER STRADLI

PREVENTION OF VENEREAL DISEASE

SIR,—Your correspondent, Dr. Forgan, in his l in your issue of July 24, misses the essential poin Lord Horder's letter published the previous week.

The campaign of the N.S.P.V.D. is directed tow the enlightenment of the public on the following poi

1. That over a long period of years the fact that v. easily preventable has been *prevented* from reaching public, and that in spite of lavish public expenditur other methods, V.D. has increased.

2. That impartial investigation by the Governn appointed Trevethin Committee settled, *once for all*, scientific fact that V.D. can be easily prevented. witnesses before that committee, including myself, prod overwhelming evidence of the dramatic reduction in that follows the introduction of self-disinfection. On subject of practicability the Trevethin report says: " *see no reason to doubt that an intelligent man, if furni with reasonable instructions, could in favourable condi effectively disinfect himself.*" The procedure is so si that any "official skilled supervision" of the disinfecti obviously superfluous. Practical experience, moreover, shown conclusively that civilians will not seek such assist and that *in the case of the Services the introductio supervision, and the elaboration of the procedure, have* the chief causes of the apparent lack of success, on acc of evasion. Officially supervised disinfection never has and never will be, successful on account of the psycholo factors involved.

3. That, incredible as it may seem, it is actually il *for a chemist to sell to any customer the necessary mate for prevention accompanied by instructions for use*

---

[1] Burgess, J. F., Pritchard, J. E. *Arch. Derm. Syph. Chicago* (in the press).

[2] Bentley, F. J. *Lancet*, 1948, i, 722.

continues in spite of the fact that the Trevethin report, in 1923, recommended that the law should be altered.

Dr. Forgan says that he has advocated prevention for many years "as a means of reducing the incidence of V.D." Then why does he disparage the idea now? If practical prevention is allowed to be known generally, it will go on reducing the incidence until elimination is reached. At present not 1% of the population know anything about it, and those who do cannot use their knowledge on account of the legal obstacle.

The N.S.P.V.D. takes no part in the controversy about compulsory notification and compulsory treatment of V.D. All such suggestions are unnecessary because V.D. is easily preventable and its successful prevention is being prevented.

R. A. LYSTER

47, Nottingham Place, London, W.1.

Chairman, National Society for the Prevention of Venereal Disease.

SIR,—Lord Horder's letter outlining the policy of the National Society for the Prevention of Venereal Disease will be welcomed by many medical men who have to deal directly with this problem. As port health officer, with experience of a number of ports in the tropics, I have always made a point of asking merchant seamen suffering from venereal disease what precautions, if any, they took. *I have been appalled by the high proportion* of men who did not know how to protect themselves and by the number who thought that a condom was sufficient protection. As M.O., before the war, to a group of trading concerns in the Far East, I interviewed each new arrival and, after stressing the moral aspect, instructed him in simple methods of prophylaxis. The striking reduction in the incidence of venereal disease among the staff was ample compensation for the open disapproval of those *who said that immorality was being encouraged.*

P.H.O.

MEDICAL RECORDS

SIR,—Those who are aware of the conditions which now prevail in the majority of hospitals cannot but be *sympathetic towards "Medical Secretary."* Undoubtedly there is truth in some of the comments she makes in her letter of Aug. 14.

She and others may feel encouraged to learn that the Association of Medical Records Officers has under consideration an educational scheme whereby it would be possible to gain additional knowledge of anatomy, physiology, and medical terminology. It is recognised that no medical secretary or stenographer can really do justice to the tasks assigned to her without such a training. The association's first responsibility is, however, *to augment the knowledge of the officers in charge of* hospital medical records departments, and through them try to improve *the standard of medical record keeping*—in so far as the laity can improve the standard. Records officers agree that medical secretaries are key people in the production and maintenance of medical records, and, as a result of the active—and long overdue—interest which has been shown in this sphere of hospital administration in the last year or two, I think they may look *forward to a much greater appreciation of the value of* their work, and to more satisfactory conditions of service, in the not too distant future.

ELSIE ROYLE,
Honorary Secretary,

Manchester.

Association of Medical Records Officers.

SIR,—"Medical Secretary" is, regrettably, correct in her statements. The qualifications and qualities outlined by her are essential for all who follow the profession of medical record keeping, which includes medical stenography whether in hospital or in private practice.

It was because of the universally acknowledged lack of training facilities for those engaged in this work in hospitals and allied organisations that an Association of Medical Records Officers was recently formed. This *association aims at raising the standard of work done,* by training courses and opportunities for the interchange of knowledge and experience for those already engaged in the work, and by laying down fundamental standards of education for those entering the profession. These requirements correspond with those of other ancillary medical services, and *it is hoped thereby to gain recog*nition of the fact that the members of this association are specialists in *their own sphere.* So far as the grapher in private practice is concerned, no doubt *interested would be welcomed in classes arranged* members of medical records departments in as was the case in my own hospital, where pai secretaries attended a course of lectures on records and subsequently a course of lectures on anat and physiology, though naturally they would not able to qualify for membership of the association.

The association also lays stress on the careful of staff—a necessity too often neglected in the past *those responsible for appointments.* The results h sometimes been unfortunate, but the misguided selec has usually been due to (1) lack of appreciation of the technicalities and responsibilities of those employed in the medical records department; and (2) the small salaries *paid in comparison with commerce and industry,* where considerably less strain and responsibility have to be borne by the stenographer. Most of the people who work in the medical records department, and in some *cases in private practice too, do so because of their love* of the work, its absorbing nature, and their desire to serve their fellow men.

RECORDS OFFICER.

OCCLUSIVE DRESSINGS

SIR,—If Bull, Squire, and Topley (Aug. 7) have done nothing more than re-emphasise the deleterious effects of adhesive plaster and such-like occlusive dressings on the skin and on wounds in general, they have done a great service. It is commonplace experience that wounds do better when covered simply—a piece of gauze held in place by two narrow strips of strapping suffices for most wounds. I have never ceased to demonstrate this to my subordinates in peace and in war.

However laudable your contributors' effort to find *a substance which will allow normal skin evaporation* to take place without being permeable to outside fluids, we must be careful, now that the age of adhesive plaster is over, to ensure that our wounds never again have coverings with similar disadvantages.

Dublin.

MARTIN FALLON.

DEATH WHILE BATHING

SIR,—*It would be interesting to know* whether some unexpected deaths while bathing might not be due to *acute prolapse of a vertebral disc.* About a year ago in my bath I was suddenly, as it seemed, cut nearly in *two by something from behind.* For ten minutes I lay in that bath paralysed and nearly fainting with pain. *Had this happened while bathing alone* in deep wat I should certainly have died.

I suggest that pathologists confronted with such cas might look and see, if there is no other obvious cause, before attributing death vaguely to cramp, heart-failure, full stomach, and the like; also, that patients subject to such attacks be warned to be careful where they bathe.

Bristol.

G. L. ALEXANDER.

CHARMS

SIR,—Dr. Lowy has written a charming and disarming letter (Aug. 7); but if he is serious, isn't he being mo than a little naïve? There is, he tells us, in the hum *personality "the deep-rooted desire for the belief in* t supernatural and unexplainable." We may deplo it but we *cannot afford to ignore* it, and "if we wish be sincere" we must admit that in some people approach on these lines *promises better* and speedi results than the employment of scientific methods.

Dr. Lowy does not say so, but *it is self-evident* th this deep-rooted desire for the supernatural an unexplainable must run counter to all advances knowledge—advances which, of course, make the general body of scientific truth less supernatural and mo explainable. Is Dr. Lowy implying that such super natural and unexplainable methods of therapy should be encouraged in physical medicine as well (he will know that cures of organic diseases have been claimed by healers), or that while purely scientific investigation and treatment should be allowed to continue in general medicine, surgery, and other subjects there sh be an honourable place for atavism and supersti in psychological medicine? It would be interesting to learn how far Dr. Lowy would go in his encouragement of the supernatural and unexplainable. Would he, for instance, agree to the treatment of a patient by teaching and instruction which he knew to be false because he believed (or felt) that it might improve the patient's symptoms? Would he acquiesce in the treatment of a patient by a ceremony designed to drive out evil spirits?

I cannot think that any verification is needed at this stage of the fact that when people become more educated and enlightened they give up these earlier beliefs in superstition and the unexplainable. The unexplainable becomes then simply a problem to be explained. These beliefs, when they remain, are an impediment to free and accurate thinking; and when they are encouraged, in children particularly, it is at the expense of the exercise of their intelligence.

But the major proposition in Dr. Lowy's argument needs further elucidation. When he speaks of the "deep-rooted desire for the belief in the supernatural and unexplainable," is he implying the existence of a direct instinctive basis for these beliefs—something in the nature of an instinct of superstition or a "metaphysical" instinct? If the beliefs are not instinctive but cultural, developed in the early years of life, is it not then a case of error and bias distorting the growing personality? And would not the sincere (Dr. Lowy's word) therapist consider it to be his duty to try to eradicate them? Or does Dr. Lowy just prefer to remain a little obscure on this point and leave it as one of his unexplainables?

I was under the impression that there had been a halt in the retreat from reason since the war. Hitler's régime in Germany was surely atavistic enough and "metaphysical" enough to show us the dangers of this attitude. For Dr. Lowy's consideration and guidance I feel I should end with a quotation from the "Grammar of Science" by Karl Pearson. It was written over 50 years ago but still apparently requires to be emphasised.

> "It is the want of impersonal judgment, of scientific method, and of accurate insight into facts, a want largely due to a non-scientific training, which renders clear thinking so rare, and random and irresponsible judgments so common, in the mass of our citizens today. Yet these citizens, owing to the growth of democracy, have graver problems to settle than probably any which have confronted their forefathers since the days of the Revolution."

London, W.1. **FREDERICK DILLON.**

SIR,—Dr. Dillon (July 24) is right; we cannot be too careful with the tender minds of children, even if we do leave colleagues in their fifties to lie in the pit of suggestibility they so often dig for others.

My own indiscretions may possibly be excused as the too enthusiastic exuberant irresponsibilities of a callow middle age newly introduced thirty years ago to the mystery of the Unconscious according to Freud. Like Adam and Eve, I thought that the nipple and knowledge grew on the same tree, and, like them, was punished; for I speedily developed an uncharming, if not altogether unpleasant, twitching of the lips whenever the subject of nipple-like excrescences was introduced. Dr. Dillon's letter caused a particularly bad attack by evoking the picture of the thousands—to put it mildly—of supernumerary nipples in the shape of 8 oz. bottles to be handed out that very day to unsuspecting victims all over the world.

Never did Nemesis fit the penalty to the crime more appropriately. The spell was broken; the gift of animistic wizardry was lost; and for a generation the moon has rolled on unperturbed by the Dick Bartonish adventures of grubby little urchins seeking relief from ugly growths which, if my fan-mail is to be trusted, still defy the skill of a highly scientific profession. Frustrated, I turned to an investigation of the common stye, with strange results.

A response to Dr. Atkin's appeal (July 24) from a lunacy centre may show that this neglect of the influence of the moon is unjustified. My own further contribution, subject to the Editor's permission, will illustrate an apparent-monthly malevolence.

Portsmouth. **W. S. INMAN.**

STUDENT NURSES' SALARIES

SIR,—Traditionally nurses have become qualified by the apprenticeship system, according to which the young worker in return for his labour receives remuneration partly in money or kind and partly in the form of instruction in the mysteries of his craft. The system is susceptible to much abuse and in the past probationer nurses have been subjected to a high degree of exploitation, but it has many innate advantages which make its retention desirable especially as the defects can probably be removed by regulation.

Systematic theoretical teaching is necessary for student nurses, but the poise and maturity of the trained nurse are gained by doing things and carrying responsibility in the wards and other departments of the hospital and not in the class-room. Even the Americans now seem to have given up the attempt to train nurses by lectures and correspondence classes—at any rate, advertisements for courses of this kind have not been prominent recently. The rawness of the newly qualified doctor compared with the trained nurse is sometimes noticeable and the necessity for medical students to learn by doing is admitted by the Goodenough Committee, which recommends that in the new curriculum the medical student shall spend at least twelve months as a junior house-officer in an approved hospital before admission to the Medical Register.

It is important to consider what the nursing apprentice (if the Royal College of Nursing will allow me to use the term) receives during her course and what it is that she gives in return. Leaving aside all imponderable considerations she receives during her first year the following:

Salary £70.

Full residential emoluments, including food with the extra rations allowed by the Ministry of Food, laundry, indoor uniform, including a cloak or cape but not shoes, stockings, or underclothing. This is nominally valued for superannuation purposes at £75, and is not subject to income-tax.

Two months' free tuition as a boarder at a preliminary training school, during which time she receives full salary.

One month's holiday with pay.

The use of a nursing library and free paper and other writing material.

Travelling expenses on first coming to the hospital, but not when going on holiday.

A rations allowance of £1 per week when on her holiday.

Full pay during illness for periods varying with the length of service, with payment of rations allowance if absent from the hospital.

Under the National Health Service Act she, like other members of the community, is entitled to medicinal drugs, but drugs of addiction like alcohol and nicotine are regarded as part of her private affairs.

After passing from the preliminary training school she continues to receive systematic teaching from the sister tutors in addition to the practical instruction given by the ward sisters, doctors, and other members of the hospital staff. At the end of a year she has received the foundations of the training which will fit her for a profession in which she is sure of making a living and in which she will have many opportunities of entering on a distinguished career suited to any special abilities which she may possess.

The main charges on her income are:

National Insurance payment 3*s.* 10*d.* per week, or £9 19*s.* 4*d.* per annum. (The employer's contribution under National Insurance is 3*s.* 3*d.* per week or £8 9*s.* per annum.)

Textbooks—she will probably wish to have some books of her own to supplement those in the nursing library.

Superannuation deductions at 6% on the value of her salary and emoluments, amounting to 14*s.* 6*d.* per month or £8 14*s.* per annum. The opportunity to qualify for a pension is a privilege which many other hospital workers would like to share, and in any case the student can claim the return of her contributions with interest if she should desire to do so on leaving the service.

The considerations given by the student in return are as follows:

Labour for 39 weeks of nominally 48 hours. The working hours are reduced by the time spent in lectures. The time spent in this way varies from 2 hours to 4–5 hours per week. Lectures are taken during working hours if this can possibly be arranged.

The figures for the later years of training need not be given here, but it should be pointed out that they are perhaps less favourable to the student.

In spite of the efforts of the Rushcliffe Committee conditions in all hospitals are not quite the same.

The problem before us seems to be to decide what is the fair and just income for a woman of 18 of this mixed status—partly a student and partly a worker—having regard to the present volume of national production. If consideration is to be given to the social and educational background we must remember that these vary very widely in the social group.

Nurses in the past have submitted to gross injustice without much protest and without being very critical of what they were told by those who benefited from their exploitation. Conditions have now changed and we find various people promising student nurses rewards which might be appropriate in a very wealthy country but would be difficult to justify here. We cannot expect the nurses to be better critics of the new leaders than they were of the old.

Perhaps the solution will have to wait for the introduction of a national wages and salaries policy, but any comprehensive scheme of this kind might disturb a great many things, including the Spens Report.

HENRY H. MACWILLIAM
Walton Hospital, Liverpool. Medical Superintendent.

TYPHUS IN NORTHERN IRELAND

SIR,—I am directed by the Minister for Health to refer to the note under this heading in your issue of July 31, in the course of which it is stated that the family of two cases of typhus reported in Northern Ireland had frequent contacts with nomad gypsy and tinker bands from the west of Ireland "where typhus is still endemic," and to inform you that no case of typhus has been reported from the west of Ireland or from any other part of Eire since 1944.

P. A. KENNEDY
Secretary.
Department of Health, Custom House, Dublin.

A TAX ON KNOWLEDGE

SIR,—Your leading article of July 10 and the ensuing correspondence has caused quite a stir among us Government medical officers. It appears that the law is against us, and it may take a long time before it will be amended. In the meantime, the following remedy has been suggested and is being seriously considered.

As law-abiding citizens we shall obey the law even if it is a bad one. Accordingly, we shall not make use in our medical work of any progress made in medicine since we obtained our professional qualifications and since we ended our postgraduate training, by virtue of which we hold our present appointments. Excepted will be such information on new developments as is given by official pamphlets, publications, training courses, or congresses which we have attended officially.

In my own case and that of eight of my colleagues, we are not to know anything of penicillin and its uses, of most of the sulpha drugs, of streptomycin, of hormonal implants (e.g., in Addison's disease), of protamine-zinc and of globin insulin, of the use of methyl thiouracil for the treatment of toxic goitre, of modern methods of rehabilitation, of electroconvulsant therapy in mental diseases, of the surgery of prolapsed intervertebral disc, of modern heart surgery, of prefrontal leucotomy, of the medical or surgical treatment of myasthenia gravis, and so on *ad infinitum.*

Mr. Justice Rowlatt and the Commissioners of the Inland Revenue may rest assured, we will uphold their decision and respect their laws!

GOVERNMENT MEDICAL OFFICER.

THE medical faculty of Bolyai University, which was established for Rumanian citizens of Hungarian origin, is anxious to obtain copies of THE LANCET. Any reader willing to share his copy with the faculty should write to Prof. Joh. Musonyi, Bolyai University, Târgu-Mureş, Rumania.

Notes and News

RESEARCH IN EIRE

IN 1947 the Eire Government accepted a scheme for B. vaccination, and by the end of this year work will be under way. The scheme is sponsored by the Medical Rese Council of Ireland, whose report[1] describes a variety investigations. Attempts to find a chemotherapeutic a for tuberculosis continue and in animal experiments sev compounds of succinic acid have been proved ineffecti Derivatives of diphenyl ether and related substances h been synthesised and tested in vitro against mycobacter and at least one shows inhibiting power at dilutions gre than one in a million. During the year 510 strains of *My bacterium* tuberculosis isolated from pulmonary cases we typed and all were found to belong to the human typ Bigger's suggestion that combined penicillin and sulph*thiazole* might cure typhoid carriers aroused much hope, but further tests on 10 carriers have shown that in only 2 was *Salmonella* eliminated. After total doses of 100 g of sulphathiazole and 57 million units of penicillin 1 out of 4 carriers became positive eight weeks later while 3 possible cures are still being examined. On the medical side, administration of urea to normal human subjects has been found to cause a decrease in the stomach's response to histamine, and the effect of 'Enterogastrone' in the treatment of pept ulcer is also being studied. A further survey of rickets in the spring of 1947 showed that 82 per 1000 of all children between the ages of 3 months and four years were affected. For children between one and four years old the incidence is about half the figure for the last two years.

MODERN APOTHECARIES

IN this century the collaboration of doctors, laboratory workers, and pharmacists in the study and preparation of complex drugs has grown steadily closer and more rewarding At the recent B.M.A. meeting in Cambridge Mr. B. J. Thomas, of Allen & Hanburys, planned on behalf of the Pharmaceutical Society, and set up, in the pathology department of the Cambridge Medical School, an exhibition which well illustrated the importance of this bond. Pharmacopœias dating from 1618 to the new 1948 *B.P.* were a fascinating, though not perhaps a very original, type of exhibit. More instructive was the section showing the stages travelled from crude drug to active principle. Curare, sticky and brown in an earthern pot, or stored in a bamboo cane or a gourd, appears, after the pharmacist's assault, as tubocurarine chloride, a sterile standardised solution for injection. Buckwheat, as a source of rutin, and *Claviceps purpurea* growing on rye, as a source of ergot, suffer a similar process of purification, a the drug emerges like a soul from purgatory without a sta on its character. Some practical demonstrations of penicill assay, new emulsifying agents, and chromatography a fluorescence used to test and isolate drugs were arresting, but the demonstration which aroused most interest was an apparatus to measure the effect of anti-histamine substances on the isolated ileum of the guineapig. A neat physiological method of this kind always gives pleasure because it implies good and delicate technique. The exhibition showed well how fortunate our profession has always been in its colleagues among the pharmacists.

SERVICE RATIONS

A GOOD deal of information was collected during the w about the suitability and adequacy of various rations for t Armed Forces. Most of this work was done in the U.S.A. a Canada, and a summary of the findings has now be written by Dr. R. E. Johnson and Dr. Robert Kark who were concerned in many of the tests.

Their report[2] describes both experimental tests of rations and surveys of rations as consumed in the American and Canadian Forces from 1941 to 1946. Many of the findings were incorporated, though somewhat belatedly, in newer scales of rations. Most of them have an application to the field of nutrition far wider than is suggested by the relatively special groups studied. For example, the importance of calories, rather than of specific nutrients, showed itself in many of the studies. If the intake of calories was below the uirements, physical and mental disturbances arose which ged from irritability to gross deterioration involving austion and collapse, and, depending on the extent of the kiency, occurred in a few weeks or in one or two days. order to avoid calorie deficiency, it was necessary that the d should be not only adequate but also acceptable. Foods t were unusual in taste, appearance, or texture, or were lly prepared, were usually not acceptable, even though s meant that the total intake was inadequate. To allow differences in individual needs, standard rations should ply more than the average needs. Special conditions ulted in special problems, such as the need for adequate l easily obtainable water-supplies in the Arctic, mobile chens to prepare hot palatable meals for armoured units, l sufficient water and salt in the desert. One interesting ervation was that troops in the most diverse climatic ditions consumed very similar proportions of proteins, l that there was no increase in the intake of fat under tic conditions.

---

[1] Annual Report of the Medical Research Council of Ireland, 1947.

[2] Published by the Quartermaster Food and Container Institute for the Armed Forces Research and Development Branch Office of the Quartermaster General, Chicago, 9, Illinois.

his report will be of considerable interest to all nutrition-, but its value would have been still greater if the rations, ribed by their official names such as B, C, K, or 10 in 1, l been given in more detail.

SPURIOUS STREPTOMYCIN

n Italy fraudulent dealers in streptomycin have been racting the drug from its containers and substituting cose, sodium bicarbonate, boric acid, or lactose. Others re labelled penicillin as streptomycin. A way of testing ubstance said to be streptomycin is given by Scanga ed in *Brux.-méd.* 1948, 28, 1624): the alleged streptomycin dded to an anaerobic broth-culture of *Bact. coli* containing thylene-blue; streptomycin inhibits the growth of *Bact.* , allowing the colour of the dye to reappear, and a decision l be come to within three hours.

RADIATION HAZARDS

A MEMORANDUM [1] prepared by the Association of Scientific rkers for the Labour Research Department, describes in ple words the types of radiations encountered in atomic-rgy and other plants, the results of their action on the nan body, and how the hazards may arise industrially. e style is perforce dogmatic, and one may forgive simplified tements except possibly: "It is fortunately not the e that any exposure to radiation, no matter how small, produce a harmful effect." In the present state of wledge, this statement is not justified: it would have n better to say that, within the present daily permissible es of radiation, adverse effects are insignificant. Also her unhappy is the remark that "a seven-hour, five-day k without overtime should be in force, and not less than weeks' annual leave is desirable for all who are unavoidably osed to intensive radiation." No worker will be exposed intensive radiation, and those exposed within the daily missible levels should need no hazard pay nor conditions ferential to other industrial workers.

RAT AND BIRD'S NEST IN AIRCRAFT

HITHERTO not much attention has been paid to the infesta-n of aircraft by rats. It was thought that rats would be ghtened by the noise of the engines and leave the aircraft the first opportunity. But a rat has lived for a month an aircraft, during which time it has put in 250 flying-urs and reached a height of 16,000 ft. The aircraft was out to take off from Saigon, it is reported,[2] when it was nd that some electric flex was cut. Sabotage was suspected, damage was repaired, and the aircraft was flown to Orly. the next trip similar damage was found, but this time the r had been bared in a spot hardly accessible to a saboteur. rat was therefore suspected, and an unsuccessful hunt was de for it at Karachi. Some fæces were found; so the t took care to leave, on the rest of the voyage, enough d lying about to make it unnecessary for the rat to gnaw . On the aircraft's return to Orly no success was obtained h poison put down for the rat. So it was decided to fly aircraft at a height of 26,000 ft. in the hope that the rat uld perish from anoxæmia; but, evidence being brought ward that rats might survive at this height, the project abandoned, and the rat was eventually caught in a trap.

In this same aircraft one of the ventilation trunks was found to be blocked by an Indomalasian starling's nest built of twigs and containing one egg. No attempt was made to hatch the egg, because it was slightly cracked and had been taken to a height of 16,000 ft.

THE JEWELLER IN BED

DIVERSIONAL occupations for patients are apt to become rather monotonous—raffia work, rug-making, belt-plaiting, painting, soft-toy making, and embroidery being the leading cults. The addition of another small skill may be welcome to patients who have wearied of the others or who never liked the look of them. At a conference last May, arranged by the Worshipful Company of Goldsmiths, and attended by representatives of the Association of Occupational Therapists, the Royal College of Nursing, the British Council for Rehabilitation, and the principals of schools of occupational therapy, it was agreed that simple jewellery and metal work might well be undertaken by long-term patients in hospitals. Mr. G. E. Gardam, PH.D., pointed out that not much skill and only simple tools are needed: and pleasant results can be achieved by people who have not done this kind of work before. Men, he thought, would prefer a craft of this kind to needlework and rug-making. Base metals such as brass, copper, aluminium, and pewter, in the form of thin softened sheets, and wire, can be used; and soft soldering can be done, by means of an electric soldering iron, without much mess. Miss B. de Foubert, a teacher of occupational therapy who had formerly been a jeweller, noted that the making of jewellery calls for initiative and imagination, qualities latent in many people, and often roused, to give great satisfaction, during a long period of convalescence. Dr. Gardam suggested that the Goldsmiths' Company might help by arranging short courses for instructors, or arranging for an instructor to tour the orthopædic hospitals and train occupational therapists. They might also issue short instructive pamphlets, showing how each article was to be made—rather on the lines of a knitting pattern. Moreover, instructors would be able to turn to them for advice on sources of tools and materials.

Mr. Claud Geoffroy de Chaume, a designer craftsman who demonstrated to the meeting, has since been given a grant by the Goldsmiths' Company to enable him to arrange demonstrations to occupational therapists, so as to show them the possibilities and limits of the craft.

University of Cambridge

On Aug. 7 the following degrees were conferred:

M.D.—E. R. Hargreaves, R. T. Hastings-Jones, R. B. Heisch, *David Verel, *F. A. Whitlock, R. R. Wilson, H. I. Winner.

M.B., *B.Chir.*—*P. H. Abbott, *Anthony Ackroyd, *Philip Allebone, *V. E. Amassian, J. C. Barker, *J. R. Bennett, *D. G. Bonham, *I. W. Broomhead, D. S. Craig, *E. J. Dowling, W. J. D. Eberlie, *C. P. E. Elliott-Binns, *D. V. G. Feltham, Paul Fehrsen, *J. E. Forster, *I. W. de G. Gregory, Ian Henderson, C. Q. Henriques, F. N. Hicks, P. J. Higgins, *J. L. Hine, *Michael Honey, *D. G. Julian, *E. A. Kauffman, *Norman Kennedy, *W. M. Keynes, H. G. L. Lloyd-Thomas, *J. A. MacDougall, A. A. McInnes, *John Mancler, P. F. D. Naylor, *G. W. Page, *C. M. B. Pare, *Harry Piggott, *Stanley Powell, *R. * By proxy.

University of Glasgow

Dr. T. Ferguson Rodger has been appointed to the newly founded chair of psychological medicine.

Dr. Rodger graduated B.SC. at the University of Glasgow in 1927 and took his M.B. with commendation two years later. After holding a house-appointment at the Falkirk and District Infirmary he spent some time in Baltimore as an assistant in psychiatry at the Johns Hopkins University. On his return to Scotland he became assistant physician at the Edinburgh Royal Mental Hospital. He returned to Glasgow as assistant to the lecturer in psychiatry at the university, and later became senior assistant physician at the Glasgow Royal Mental Hospital and assistant consultant in psychiatry at the Western Infirmary. He also acted as hon. secretary to the Scottish Child Guidance Council. During the late war he served with the R.A.M.C., and with the rank of brigadier he was consulting psychiatrist at H.Q. Land Forces, South-East Asia, and at General H.Q., India. Dr. Rodger is now a commissioner of the Scottish Board of Control. His published work includes papers on night-blindness and personnel selection. He obtained the D.P.M. in 1931 and the F.R.C.P.E. last year.

Edinburgh Post-Graduate Board for Medicine

On Friday, Aug. 27, at 3.30 P.M., in the anatomy theatre of Edinburgh University, Prof. Alexander Haddow will lecture on the Present State of Chemotherapy in Cancer.

The Protection of Workers from Radiation Hazards in atomic energy plants and other establishments using radioactive substances. Pp. 21. 1s. From the association, 2, Soho Square, London, W.1.

Tanon, Boyer, Tourret, *Bull. Acad. Méd. Paris*, 1948, 132, 420.

University of London

The appointment of Dr. T. Crawford and Dr. D. V. Davies to the chairs of pathology at St. George's and of anatomy at St. Thomas's was announced last week.

Dr. Crawford is a graduate in medicine and science of the University of Glasgow, where he qualified in 1935. In 1938 he was awarded the Hall tutorial and research fellowship in pædiatrics there, and he also held a house-appointment at the Royal Hospital for Sick Children. Later he was appointed assistant pathologist to the Royal Infirmary and lecturer in pathology in the university. During the late war he served with the R.A.M.C. with the rank of major, as a specialist in pathology. In 1941 he was awarded the Bellahouston gold medal for his M.D. thesis. Since 1946 he has been director of pathological services at St. George's. His published work includes papers on carbohydrate tolerance in hypothyroidism and hyperthyroidism and on the causation of the low blood-sugar curve in cœliac disease.

Dr. Davies, who is a fellow of St. John's College, Cambridge, qualified from University College Hospital in 1935 and took his M.B. Lond. the same year. After holding house-appointments at U.C.H. he became demonstrator in anatomy, and later lecturer, in the University of Cambridge. In 1945 he was an Arris and Gale lecturer at the Royal College of Surgeons. He is an examiner in anatomy for the Conjoint Board and for the University of Cambridge, and since 1944 he has been college lecturer in anatomy at St. John's. His published work has been chiefly concerned with the synovial membrane and fluid.

Mr. R. T. Williams, D.SC. has been appointed to the university chair of biochemistry at St. Mary's Hospital medical school.

Royal College of Obstetricians and Gynæcologists

On Friday, Oct. 1, at 2.15 P.M., Dr. Emil Novak, associate in gynæcology at Johns Hopkins Medical School, Baltimore, will give a lecture on Certain Functioning Tumours of the Ovary. On the following day, Oct. 2, at 10 A.M., Dr. N. W. Philpott, professor of obstetrics and gynæcology in McGill University, Montreal, will deliver the William Blair Bell lecture. He is to speak on Rhesus Factor Iso-immunisation and Hæmolytic Disease of the Newborn. Tickets for both lectures may be had from the secretary of the college, 58, Queen Anne Street, London, W.1.

Dentists in the Health Service

The Ministry of Health announce that up to Aug. 7, out of an estimated total of 10,000 dentists in general practice, 6654 had entered the National Health Service.

Rockefeller Travelling Fellowships in Medicine

The Medical Research Council have awarded the following Rockefeller fellowships for 1948–49:

Dr. K. W. DONALD, medical professorial unit, St. Bartholomew's Hospital, London.

Dr. L. P. R. FOURMAN, Nuffield department of clinical medicine, University of Oxford.

Dr. R. H. GIRDWOOD, department of medicine, University of Edinburgh.

Dr. A. ISAACS, department of medicine, University of Sheffield.

Mr. A. I. S. MACPHERSON, department of surgery, University of Edinburgh.

Dr. H. B. STONER, department of pathology, University of Sheffield.

Mr. S. F. TAYLOR, department of surgery, Postgraduate Medical School of London.

British Rorschach Forum

At a recent meeting convened by Dr. C. J. C. Earl, the original forum, which had been an informal group and never properly constituted because of war conditions and other difficulties, was dissolved and reconstituted. The objects of the new forum are to facilitate the exchange of views among those using the test, to safeguard professional standards in the use of the method, and to encourage research among Rorschach workers. The officers of the forum are Dr. Earl (chairman), Miss Theodora Alcock (secretary), Dr. W. Mons (treasurer). Further information may be had from the secretary, c/o the Tavistock Clinic, 2, Beaumont Street, London, W.1.

Courses for Public-health Nurses

The National Health Service Act offers increased opportunities for health education by public-health nurses, and the Central Council for Health Education is, therefore, providing a two-day course of lectures for health visitors, midwives, district nurses, and school nurses on this aspect of their work in the following university centres: Birmingham, Sept. 13–14; Bristol, Nov. 1–2; Cambridge, Oct. 18–19; Cardiff, Oct. 25–26; Leeds, Oct. 4–5; Liverpool, Sept. 20–21; Manchester, Sept. 23–24; Newcastle, Oct. 14–15; Oxford, Oct. 11–12; Sheffield, Oct. 7–8; Courses are also being arranged in Belfast, London, Middlesex, Essex, Kent, and Surrey. Particulars can be had from the medical adviser and secretary of the council, Tavistock House, Tavistock Square, London, W.C.1.

Westminster Medical School

Mr. W. T. S. Stallybrass, D.C.L., vice-chancellor of University of Oxford, will deliver the inaugural add this school, 17, Horseferry Road, S.W.1, on Monday, O at 3 P.M.

British Standards

A new standard (B.S. 1443), published by the B Standards Institution, specifies the size of X-ray film intensifying screens, together with internal sizes of ca adopted for future use. The committee charged with work has found it possible to provide satisfactorily f uses with a range of 10 inch-sizes and 6 metric-sizes; 16 sizes will replace more than 30 formerly in use. has been taken to ensure that films and screens of the standard sizes will be capable of use in all existing equip

The institution's Hospital Equipment Standards Adv Committee, formed at the beginning of 1947, has an account of its work up to date. This report (P.D. price 6*d.*) is obtainable from the institution, 24, Vi Street, London, S.W.1.

Sir Hugh Cairns, Nuffield professor of surgery at O has left for South Africa, where, as Arthur Sims trav professor he is to lecture at Johannesburg, Durban, Cape Town.

Appointments

BECK, DIANA, M.B. Lond., F.R.C.S., F.R.C.S.E.: neurosur Middlesex Hospital, London.

TAYLOR, L. R. S., B.A., M.B. Camb., F.R.C.S.: chief assistant to nose, and throat department, St. Thomas's Hospital, L

Colonial Service:

- BEARBLOCK, ARTHUR, F.R.C.S., D.T.M. & H.: superscale medical and health officer, grade B, Federation of Malaya
- BLAND, R. H., O.B.E., M.D. Dubl., M.R.C.P.I.: senior leprosy officer, Nigeria.
- COOPER, S. W., F.R.C.S.E., D.T.M. & H.: surgeon specialist, Gold Coast.
- DEGAZON, D. W. A., M.B. Lond., F.R.C.S.E., D.O.M.S.: M.O. (specialist), Jamaica.
- EVANS, W. G., M.B., B.SC. Wales: superscale medical and health officer, grade B, Federation of Malaya.
- FARQUHARSON, A. D. J., M.R.C.S.: M.O., Nigeria.
- HOLMES, W. E., M.A., M.B. Dubl., D.P.H., D.T.M. & H.: super medical and health officer, grade B, Federation of Mala
- JACKSON, P. F., M.B., B.SC.: M.O., Uganda.
- KERR, N., M.B. Edin.: M.O., Bahamas.
- LOVETT, W. C. D., M.D., B.SC. Wales, C.P.H.: M.O., B Somaliland.
- LOWE, G. H., M.B. Leeds, D.P.H.: superscale medical and officer, grade B, Federation of Malaya.
- MCGREGOR, J. S., M.D., M.SC. Edin., F.R.C.S.E., D.T.M & surgeon specialist, Gold Coast.
- MOODIE, A. S., M.B. Glasg., D.P.H.: M.O., Hong Kong.
- PORTER, G. E. J., M.R.C.S.: M.O., Gambia.
- RAINSFORD, C. R. C., M.D. Belf., D.T.M.: senior M.O., Uganda.
- ROBERTS, F. R., L.R.C.P.E.: M.O., Gold Coast.
- RUSSELL, BEATRICE, M.D. Edin., F.R.C.P.E., D.T.M. & H.: ph specialist, Gold Coast.
- STRUTHERS, E. A., M.B. St. And., D.P.H., D.T.M. & H.: de director of medical services, Federation of Malaya.
- SUGAR, MAX, M.D., F.R.C.S.E.: M.O. (specialist), Jamaica.
- SWORD, J. M., M.B. Glasg.: M.O., Nyasaland.

Births, Marriages, and Deaths

BIRTHS

BINKS.—On Aug. 1, at Chadderton, to Dr. Margaret Binks, wife of Dr. Paul Binks—a son.

FRASER.—On Aug. 8, at North Bovey, Devon, the wife of D D. B. Fraser—a son.

GLASS.—On Aug. 9, in London, to Dr. Norma MacLeod, wife of Dr. R. M. Glass—a daughter.

HODGE.—On Aug. 11, at Bridgwater, Somerset, the wife of D Gerard Hodge—a son.

KENNEDY.—On Aug. 8, in London, the wife of Dr. Gordon Ken —a daughter.

PRAGNELL.—On Aug. 5, the wife of Dr. C. A. Pragnell—a so

TODD.—On Aug. 11, at Guildford, the wife of Dr. J. W. Todd—a

MARRIAGES

FREW—HAWTREY.—On Aug. 7, at Aldershot, Thomas Pat Frew, M.B., to Caryll Courtenay Hawtrey.

OPPÉ—BUTCHER.—On Aug. 5, at Orpington, Thomas Ernest O M.R.C.P., to Margaret Mary Butcher.

DEATHS

ARNOLD.—On Aug. 6, at Worthing, Miles Bracewell A M.D. Manc., D.P.H.

MAITLAND.—On Aug. 10, Thomas Gwynne Maitland, M.A., B B.SC., D.PHIL., Edin.

SUTHERLAND.—On Aug. 14, in Edinburgh, Francis Suther M.B. Edin., D.P.H.

HE SELECTION OF MEDICAL STUDENTS

A. D. HARRIS
M.R.C.S.

rom the Medical Research Council Unit for Research in Applied Psychology, Psychological Laboratory, Cambridge

IN 1869 Paget wrote a short paper called "What ecomes of Medical Students," taking his title from a tory told of Abernethy, who entering the anatomy heatre for one of his introductory lectures "looked ound at the crowd and exclaimed, as if with painful oubt, 'God help you all! What will become of you?'" n trying to answer this question, Paget and two of his olleagues drew on personal knowledge of 1000 students ney were able to trace out of 1226 who had passed rough their hands between 1839 and 1859. Of this 000 they estimated that 23 achieved distinguished ccess, 66 considerable success, 507 fair success, 124 ery limited success, and 56 failed entirely. Also epresented in the 1000 were 96 who left the profession, 7 who died within twelve years of starting practice, nd 41 who died during pupillage.

Galton (1889), who used Paget's figures to exemplify ertain characteristics of frequency distributions, indicated uccinctly the range of talent found in this group of octors:

> "In the present case it appears that towards the foremost of the successful men within 15 years of taking their degrees stood the three Professors of Anatomy at Oxford, Cambridge, and Edinburgh; that towards the bottom of the failures lay two men who committed suicide under circumstances of great disgrace, and lowest of all Palmer, the Rugeley murderer, who was hanged."

alton further comments that in this paper Paget thus did for St. Bartholomew's Hospital what has ever been done, so far as I am aware, for any university r public school, whose historians count the successes nd are silent as to the failures, giving to inquirers o adequate data for ascertaining the real value of those nstitutions in English education."

Eighty years after Paget wrote, the case is little etter, though discussion in recent years on the selection f students has given us fresh cause to inquire "what ecomes of medical students."

The problems involved in selecting medical students ave been admirably discussed by Smyth (1946). Briefly, he number of applicants for admission to medical chools has risen greatly and shows no sign of falling gain. The ratio of applicants to available places varies or different medical schools between 20 to 1 and $2^{1}/_{2}$ to 1. It had been anticipated that an increase would occur after the war—the so-called "post-war bulge"—but it is clear that something more has happened. A further reason for the increase is the better financial provision for students by means of grants and scholarships. This applies equally in all faculties of the universities; but it is in the medical faculties that congestion is most extreme. It seems that there has been a definite shift n preference towards medicine. Besides the problems reated by the increase in number of applicants there as for some time been uneasiness about the quality f some of those accepted. It has been felt that perhaps aluable recruits were being turned away, and it was een that some of those who were taken later proved unsuitable.

Before the war it was usual for candidates to be nterviewed by the dean or his representative. The nterviews were generally perfunctory but served to xclude those whose unsuitability was conspicuous. In ome schools it was found that even this brief encounter ould be dispensed with, and candidates were accepted n school record or headmaster's recommendation. As he number of applicants began to rise, one medical school after another found it necessary to introduce more stringent methods and to spread more widely the labour and responsibility involved. Most of them relied on improved interviewing systems, in which several members of the teaching staff constituted either a selection board, the members sitting together, or a panel of interviewers each of whom saw a proportion of the candidates. More detailed forms of application were introduced, and attempts were made to reduce the numbers for interview by preliminary exclusion on the basis of the information thus provided. In at least two English medical schools a written examination has been used as a "sieve" for the same purpose.

METHODS OF SELECTION

It was natural to inquire whether any help could be expected from the experience of those faced with similar problems in industry and the Armed Forces. The answers given have not been entirely satisfactory. Perhaps the question has been put in terms too general; certainly this has been true of the replies. What are called "selection methods" or "psychological methods of selection" have been advocated or rejected as if they constituted a uniform type of procedure, different in kind from the ordinary methods of choice between rival candidates. It is clear that selection is exercised whenever the number of candidates exceeds the number of places for which they are competing, and presumably the term "selection methods" comprehends any of the ways in which this can be done. It would further be questionable whether the adjective "psychological" can legitimately be withheld from any method which includes at least an interview. The misnomers would not be important if the meanings were generally agreed. However, this is not so. These blanket terms are used to cover any procedure ranging from a single pencil-and-paper test to a week-end at Stoke d'Abernon; and this naturally leads to a certain imprecision of judgment. Thus it has been suggested that the "W.O.S.B. technique" should be used for selecting medical students, though there is no very obvious connexion between those features of W.O.S.B. which appear to be new or distinctive, namely techniques for assessing leadership, and the qualities required of a medical student.

The term "selection methods" is used here in its common sense to mean any method whatever by which a choice is made between candidates. It does not appear useful to class together all the newer methods by calling them "psychological" or anything else. Particular techniques—e.g., interviews, intelligence tests, projection tests, interest questionnaires, &c., are best treated separately. Eysenck (1947) has given a valuable review of several specific techniques in relation to examination success in university students. It would be useful if a similar account could be given, by those with first-hand experience of Service methods, of those particular techniques which might be thought relevant.

THE INTERVIEW

The interview is the most important instrument of selection in use today. It is as unlikely that any development in testing practice will supersede it as that laboratory aids to diagnosis will supersede the clinical examination of patients.

At many medical schools the board interview has been adopted as a means of ensuring that the fate of candidates is not decided by the bias of a single interviewer. Two things must strike anyone who has watched these board interviews taking place. The first is the formidable difficulties that the boards must contend with. Time is very short; often less than five minutes, rarely more than ten, can be given to any candidate. The candidates are nervous and "unnatural"; sometimes they may be thrown right off their balance by an injudicious opening question or by the number and eminence of their audience. Most of all one is struck by the paucity of information available to the board; continually they are in the position of the clinician asked to make a diagnosis when not only the laboratory reports but even the case-history is withheld from him. This is brought home most vividly when, as sometimes happens, a candidate is known personally to a board member who may, after the candidate has gone out, be able to produce for the board some of the missing data on which a judgment should be based. It is sometimes plain on these occasions that the information normally available to the board is but a small part of what needs to be known.

The second point is that, despite these difficulties, there is among the members of most medical-school boards at least one whose deftness marks him out, who succeeds in putting the candidates at ease and getting them to talk, and whose judgment one feels to be nicely balanced. How this is done remains mysterious. The ability is highly complex and usually quite unformulated in the minds of its possessors. It is unpopular to speak of any form of individual judgment as a reliable instrument, but it seems to me that there can be little doubt that it is sometimes not only reliable but amazingly sensitive. It is true that the best interviewers are not necessarily those who believe themselves so; and, as Smyth (1946) has pointed out, it is very important to find means of identifying the persons who show this ability most markedly.

At other schools the candidates are seen by a single interviewer, whose personal quality is all-important. Another method, introduced by Buzzard (1944) for certain types of interview in the R.A.F., has not, so far as I am aware, been given a trial by any medical school. In this an attempt is made to combine the advantages of interviews by a board and of interviews by one person. The members of a board, working on this system, act for half the available time as a panel of interviewers, each seeing a proportion of candidates for a fairly long interview, and later sit as a board to see briefly all the candidates.

For example, suppose that 60 candidates are normally seen for ten minutes each by a board comprising 6 members: this will take ten hours. If, instead, each member of the board interviews 10 candidates individually for half an hour each, there still remains time for the board sitting together to see every candidate for five minutes. This means that for every candidate there is one member of the board who has a considerable amount of information, gained under conditions more favourable to the assessment of personality than is the atmosphere of a board interview, and in many cases his considered judgment can be accepted by the board without more ado. The later interview with the board does, however, provide some check on the aberrations of individual judgment, particularly where members of a board are well acquainted with each others' foibles. Unlike many other suggestions for improved interviewing, this does not mean increasing the time spent by any member of a committee. In fact, in R.A.F. experience, it may actually reduce it. On the other hand, the time allotted to each candidate rises—in this example from ten minutes to thirty-five.

THE USE OF TESTS

Usually there are three ways in which a test can be devised. It may consist of a sample of the performance for which it is intended to be a test, or mimic it as closely as possible. This type of test is often successful, particularly in dealing with manipulatory skills, and sometimes surprisingly unsuccessful. It seems to be less successful the higher the ability concerned, largely because of the difficulty of securing a representative sample of a complicated performance.

The second form of test is based on an analysis of the performance in terms of separate abilities. This applies to the breakdown of complex motor skills into smaller functional units, and equally to the analytic proc which have been used in the Services in which qualities, such as intelligence, manual dexterity, believed to relate to the job in hand are abs and tested separately. The attempt to isolate pa faculties for the profession of medicine is likely to unprofitable, or so it appears at the moment. This to be because so many different activities are rep in the profession that it is found either that they practically nothing in common except a reaso standard of intelligence and personal integrity or the the prescription is composed of the cardinal virtu in aliquot parts. This is reassuring for those who hav already attained a medical qualification but not of muc practical value as a guide to selection.

Lastly, the tests can be empirically derived. In present connexion this entails a deliberate search those variables which give maximal discrimin between the proficient and the unproficient. In present state of applied psychology there is a deal to be said for empiricism intelligently used. Penrose (1947) points out, "from the point of view research, it is always advisable to proceed from known to the unknown"—to start with differen which are large enough to be unmistakable, and examining these differences and their correlates to the most efficient method of discrimination, which can then be applied to the border-line cases. It is when empirical relations are well established that causal principles can be hopefully sought.

INTELLIGENCE TESTS

Intelligence testing is the best established of all test methods. It has proved its value time and again where rapid separation over a wide range of talent is desired. When, however, the range is fairly narrow, particularly when it is at the upper end of the scale, new difficulties appear. It is extremely important to ensure that the test is appropriate to the group for which it is designed. The more obvious effects of failing to do this are seen the gross departures from normality of distri which appear when certain tests are given to univer students, the candidates bunching together at the end of the scale of marks (Edholm and Gibson 19 This may be corrected in a purely arithmetical by lengthening the test, shortening the time, or va the rate of increase of difficulty of the questions, but it is likely that devices of this kind merely accentuate the speed factor which is already too important in many current tests. There is a good deal of research going on today to explore the conditions of "appropriateness," and to find how they may be attained without either accentuating the speed factor or compromising the logical rigorousness of the tests.

It is sometimes overlooked that an intelligence test must not only be appropriate; like justice, it must be seen to be manifestly so. That is to say, trivial or childish questions must not be asked of an adult sophisticated assembly. There is a perfectly justifiable annoyance with tests of this kind. The debate in the House of Lords (1948) on Civil Service selection produced several examples.

Another point is that the test should not be confined to one medium of expression—to words, numbers, or diagrams exclusively. There is evidence that the differential effect of the medium of expression becomes more marked the higher up the scale you go; and, unless it can be shown that one medium is of greater diagnostic importance in a particular setting, it seems safer to include all three.

Two further difficulties remain to be considered. The effect of practice on these tests is not entirely certain, either where a man has done a single test of a different kind at some previous time, or where there has been liberate coaching. It cannot be denied that practice fects scores on intelligence tests—it is difficult to nceive why anyone ever thought otherwise—and recent ork suggests that in certain circumstances it may fect them far more than was thought. It will probably important also, if these tests are to be used for edical students, to examine more closely the effect of ugs such as caffeine, amphetamine, and glutamic acid. is generally thought at the moment that these sub- ances may improve scores, by increasing speed of orking, but not sufficiently to be of practical importance.

OTHER TECHNIQUES

The search for what are generally called "specific titude" tests is likely to be something of a will-o'- e-wisp so far as the medical profession is concerned. ere are far too many such aptitudes required in some gree by all doctors, and apparently none required in gh degree by all doctors. This is not to say that specific titude tests may not be important in advising intending ecialists, though their value has still to be shown.

Interest questionnaires may perhaps be of value, but st are American and need careful revision if they to be tried under English conditions. However, the essment of direction and extent of interest ought to possible, and would be likely to have much selective lue. Temperament tests and questionnaires are nerally disappointing. Perhaps temperament is too id a concept ever to be assessed by cut and dried thods; possibly the difficulty is that it is only at very extremes of the scale that we have any clear a of what we are looking for. Finally there remain ts of achievement—of realised, and not potential, pacity. These are now being used extensively in nerica. They differ only from the traditional written aminations in that greater care is taken to cover a resentative sample of the field of knowledge that is ng examined, and generally some form of multiple- ice question is used to make marking speedier and re objective. School records and ordinary written aminations have been used for the same purpose. eir disadvantage is that they necessarily measure lievement in some anterior discipline, which may or y not be relevant. However, most of the evidence ggests that the best prediction available at the moment based on a combination of a suitable intelligence test d some record or examination of scholastic achievement senck 1947, Salter 1942, Moss 1933).

CONSISTENCY AND VALIDITY

onsistency is also called "reliability," but the word misleading and is dropping out of use. A test is arded as consistent when it gives a similar rank order ong subjects in successive trials, or when two halves a test give a similar rank order. These two criteria distinct. In the split-half estimation alternate ms of the test are taken to constitute the two halves, d the correlation between them is found for a group subjects. The correlation will be reduced if the test iterial is grossly heterogeneous, or if the form is such at chance plays an important part in determining responses given. In the test-retest estimation there the further factor of day-to-day fluctuation in the res of individual subjects. The effect of practice, if cts differentially in different parts of the score range, y also upset the correlation.

alidity is estimated by comparing test results with e criterion external to the test, such as measurements proficiency, and ratings of success in a particular upation. Obviously nothing can be learnt about the idity of a test from test results alone.

t will be apparent that a test may be perfectly sistent without being valid in any degree, but that validity is limited by its consistency. Both consistency validity are best measured by the ordinary methods of correlation, which give values ranging from zero, when there is no relationship, to + 1 or − 1, when there is perfect positive or negative association. Such coefficients are useful working tools in evaluating a test in a particular situation. They have no absolute meaning, and their extension to any different situation carries the usual dangers of extrapolation. In general, smaller coefficients are to be expected with more highly selected groups, because of the restriction in variance.

The word "test" has been used in discussing consistency and validity, but there is no reason why other methods of selection should not be examined in the same way. Certainly any form of written examination can be so treated, with results which sometimes surprise those who regard examinations as better founded than intelligence tests.

MEDICAL RESEARCH COUNCIL INVESTIGATION

A planned attack on the problem of selecting medical students has been advocated for some time (*British Medical Journal* 1946, Bartlett 1946, Barling 1948) and a start has now been made under the ægis of the M.R.C.* on a long-term investigation in which it is proposed to follow up a year's entry at several medical schools. An intelligence test which is judged suitable has been given to these students in their first year, and in certain schools various other tests have been used. It is the aim that the investigators should get to know the students included in the follow-up by a series of informal interviews and, where possible, under the conditions of their daily work.

The interviews are biographical in type. They are designed to gather as reliably as possible certain information about the student's past history; his family and social background, childhood and education; Service record; and present interests and habits of study. At first three-quarters of an hour was allotted to each student; later the time was raised to an hour, since it is important, where full records are required, that there should be five or ten minutes left after a candidate has been seen before the next is due. This allows for the completion of the interviewer's notes and gives him a chance to think about the information he has elicited. An ad-hoc rating system has been used to compare the students as regards certain temperamental qualities; but the emphasis has lain on recording facts rather than interpretations or impressions.

These interviews and tests are given in the first year of training. In the follow-up, assessments are to be obtained at each stage from teachers and others in contact with the students. The results of professional or college examinations will also be used to give a picture of the students' progress. Particular attention will be given to defining the proximate cause of failure in those who drop out.

Four features of the investigation may be emphasised:

(1) Tests which can be objectively scored and which may eventually prove of practical value in selection are being given but will be regarded as ancillaries in the general survey. Though it will be important to examine the relation of test results to standards of achievement, the validation of tests in this context is not regarded as the only, or necessarily the most important, object of the investigation.

(2) These tests are given experimentally; it is not proposed that they should be used to influence the

---

* An advisory committee for this investigation was constituted by the Medical Research Council in December, 1947. The members are Prof. Sir FREDERIC BARTLETT, F.R.S. (chairman), Prof. ESTHER KILLICK, Prof. J. PATERSON ROSS, Prof. L. S. PENROSE, Prof. D. H. SMYTH, Prof. CLIFFORD WILSON, and Dr. A. D. HARRIS (secretary). Besides advising directly on the conduct of this research, it is hoped that this committee will fill a valuable place in keeping other workers in touch by the circulation of accounts from time to time of projects undertaken at other medical schools.

injudicious opening question or by the number and eminence of their audience. Most of all one is struck by the paucity of information available to the board; continually they are in the position of the clinician asked to make a diagnosis when not only the laboratory reports but even the case-history is withheld from him. This is brought home most vividly when, as sometimes happens, a candidate is known personally to a board member who may, after the candidate has gone out, be able to produce for the board some of the missing data on which a judgment should be based. It is sometimes plain on these occasions that the information normally available to the board is but a small part of what needs to be known.

The second point is that, despite these difficulties, there is among the members of most medical-school boards at least one whose deftness marks him out, who succeeds in putting the candidates at ease and getting them to talk, and whose judgment one feels to be nicely balanced. How this is done remains mysterious. The ability is highly complex and usually quite unformulated in the minds of its possessors. It is unpopular to speak of any form of individual judgment as a reliable instrument, but it seems to me that there can be little doubt that it is sometimes not only reliable but amazingly sensitive. It is true that the best interviewers are not necessarily those who believe themselves so; and, as Smyth (1946) has pointed out, it is very important to find means of identifying the persons who show this ability most markedly.

At other schools the candidates are seen by a single interviewer, whose personal quality is all-important. Another method, introduced by Buzzard (1944) for certain types of interview in the R.A.F., has not, so far as I am aware, been given a trial by any medical school. In this an attempt is made to combine the advantages of interviews by a board and of interviews by one person. The members of a board, working on this system, act for half the available time as a panel of interviewers, each seeing a proportion of candidates for a fairly long interview, and later sit as a board to see briefly all the candidates.

For example, suppose that 60 candidates are normally seen for ten minutes each by a board comprising 6 members: this will take ten hours. If, instead, each member of the board interviews 10 candidates individually for half an hour each, there still remains time for the board sitting together to see every candidate for five minutes. This means that for every candidate there is one member of the board who has a considerable amount of information, gained under conditions more favourable to the assessment of personality than is the atmosphere of a board interview, and in many cases his considered judgment can be accepted by the board without more ado. The later interview with the board does, however, provide some check on the aberrations of individual judgment, particularly where members of a board are well acquainted with each others' foibles. Unlike many other suggestions for improved interviewing, this does not mean increasing the time spent by any member of a committee. In fact, in R.A.F. experience, it may actually reduce it. On the other hand, the time allotted to each candidate rises —in this example from ten minutes to thirty-five.

THE USE OF TESTS

Usually there are three ways in which a test can be devised. It may consist of a sample of the performance for which it is intended to be a test, or mimic it as closely as possible. This type of test is often successful, particularly in dealing with manipulatory skills, and sometimes surprisingly unsuccessful. It seems to be less successful the higher the ability concerned, largely because of the difficulty of securing a representative sample of a complicated performance.

The second form of test is based on an analysis of the performance in terms of separate abilities. This applies to the breakdown of complex motor skills into smaller functional units, and equally to the analytic proced which have been used in the Services in which ce qualities, such as intelligence, manual dexterity, believed to relate to the job in hand are abstr and tested separately. The attempt to isolate partic faculties for the profession of medicine is likely to unprofitable, or so it appears at the moment. This to be because so many different activities are represe in the profession that it is found either that they practically nothing in common except a reason standard of intelligence and personal integrity or the prescription is composed of the cardinal virt in aliquot parts. This is reassuring for those who ha already attained a medical qualification but not of m practical value as a guide to selection.

Lastly, the tests can be empirically derived. In present connexion this entails a deliberate search those variables which give maximal discrimina between the proficient and the unproficient. In present state of applied psychology there is a deal to be said for empiricism intelligently used. Penrose (1947) points out, "from the point of view research, it is always advisable to proceed from known to the unknown"—to start with differen which are large enough to be unmistakable, and examining these differences and their correlates to the most efficient method of discrimination, which then be applied to the border-line cases. It is when empirical relations are well established that causal principles can be hopefully sought.

INTELLIGENCE TESTS

Intelligence testing is the best established of all test methods. It has proved its value time and again where rapid separation over a wide range of talent is desired. When, however, the range is fairly narrow, particularly when it is at the upper end of the scale, new difficulties appear. It is extremely important to ensure that the test is appropriate to the group for which it is design The more obvious effects of failing to do this are seen the gross departures from normality of distribut which appear when certain tests are given to universi students, the candidates bunching together at the t end of the scale of marks (Edholm and Gibson 194 This may be corrected in a purely arithmetical se by lengthening the test, shortening the time, or varying the rate of increase of difficulty of the questions, but it is likely that devices of this kind merely accentuate the speed factor which is already too important in many current tests. There is a good deal of research going on today to explore the conditions of "appropriateness," and to find how they may be attained without either accentuating the speed factor or compromising the logical rigorousness of the tests.

Two further difficulties remain to be considered. The effect of practice on these tests is not entirely certain, either where a man has done a single test of a different kind at some previous time, or where there has been

PSYCHIATRIC SCREENING OF MEDICAL STUDENTS

R. Orton
M.D. Leeds, D.P.M.
SENIOR LECTURER

D. R. Martin
B.A.
CLINICAL PSYCHOLOGIST

From the Department of Psychiatry, University of Leeds

At Leeds University the increase in the number of pplicants for places in the medical school has become so reat that selection has become a serious problem. At resent about 400 prospective students have to be nterviewed between January and June. Out of this umber about 75 can be accepted. There are signs that ie number of applicants will rise still further.

The present method of selection is best described as ie "old method"—i.e., a personal interview by three terviewers. The Board of the Faculty of Medicine ive appointed a panel of about fourteen interviewers. wo of this panel, plus the senior administrative officer, rm an interviewing committee. The numbers of pplicants necessitate about three interviewing sessions week throughout two terms. These sessions last nearly ree hours, and about ten candidates are seen. This lows about fifteen minutes per interview. On the hole, it will be impracticable to increase the number of ssions, and an increase in the number of applicants ill lead to decreased interviewing time to the detriment its reliability.

The interview technique is non-standardised, and the ndidate is assessed on his academic achievement and rsonality. Personality is assessed as a result of a ide range of questions on the candidate's reasons for siring medicine as a career and on his general interests d activities. His general demeanour, &c., undoubtedly ve a subjective influence on the interviewers, and this luence is probably of as much importance in formulat- g an opinion as are the answers given to questions. hether it is as reliable as more objective factual ormation is open to question.

One of us (R. O.) has been a member of the interview- g panel and felt that it should be possible to develop echnique which would enable us to screen from the ss of applicants those who would be considered totally suitable by an interviewing committee. It was not gested, nor is it felt, that psychiatric selection should lace the old method; rather is it suggested that the t of both methods be used. If screening can leave out 250 candidates for interview and reliably pick the bottom 150, it would give the interviewing mmittee more time per candidate, which should rease their reliability. If the number of applicants reases much, some such technique will become a cessary evil. To many people the emphasis will be ced on the word "evil," but the word "necessary" certainly of equal importance.

There is much criticism from all quarters of modern ection procedures; the War Office Selection Board and its Civil Service equivalent being heavily criticised by many. The Conference of the Home Universities (1947) had a long discussion on the basis of selection of students. This discussion brought out most of the arguments for and against modern selection procedure—particularly against. There was little criticism of the older examination methods and a too ready acceptance that the examination was a reliable indicator of academic achievement. To quote Dr. J. F. Mountford: examinations "provide a simple and reasonably reliable means of ascertaining whether a given academic standard has been reached. They testify not only to a measure of intellectual ability but also to industry, without which no university course can profitably be pursued." This is a generally accepted view—accepted, however, without criticism or investigation. Yet Vernon (1940) states that "most examinations are very defective methods of measuring the achievements or the future promise which they set out to measure." He gives what appears to be good evidence in support of this statement throughout his book.

Whatever criticism there may be about the so-called intelligence tests, inter-test correlation is fairly high, and the results obtained by different testers on the same person show a high degree of agreement. Different examinations to test the same knowledge and different examiners are apt to, and do, produce widely differing results. This fact is conveniently forgotten by those who criticise modern testing procedure. It is unfortunate, however, that tests of intelligence have been used by relatively untrained people. There are many pitfalls, and intelligence testing is not something which can be done by anybody—it is an expert's job.

In approaching the problem of screening prospective students we were well aware of the many difficulties. Above all, such a method should be fair. No-one rejected by such technique should even be a border-line possibility. All "possible" medical students should be interviewed, because the interview is regarded as a fair method. In this country not only must justice be done but also it must be apparent that it is done. The main objection of most people to psychological testing is its "secretive" nature, and it is therefore impossible for all and sundry to assess its fairness. To summarise, psychological testing procedure has many pitfalls but, on the whole, the awareness of these does not only rest with those opposed to it. In fact, those concerned with psychological testing are usually aware of more difficulties than are those in the opposing camp.

OBJECTS OF THIS SURVEY

Before one can begin to use screening, one must first know something about what one is trying to find. Accordingly we decided to test a group of known medical students to obtain some "norms." It was also a means of trying out our preliminary test material which we knew would probably require amendment in the light of experience. Ultimately we hope to test groups of applicants (30–40 in a group) but not to influence selection by the present method. In two years we should have some indication of the reliability of our methods by following up students. In particular, we would be interested to see how "our" failures, who were accepted after interview, progressed.

We had hoped to obtain material from about 100 students. We picked a random sample of 100 and asked for volunteers. Unfortunately, end of term and pressure of work prevented many students from attending, added to which many did not volunteer. This has spoilt our sample, since it is likely that more inadequate students would volunteer less readily, and our numbers are small. We hope to extend our survey until we have sufficient material to provide us with an adequate guide to the "medical student."

students' career in any way. It has been objected that test scores may be affected by the putative importance to the student of doing well in the test, and that correlations may be misleadingly low under the experimental conditions of this inquiry. However, the choice is not an open one. Medical schools are rightly not prepared to use these tests effectively without some evidence of their value. Nor would it be at all easy to get evidence for validation purposes, if the follow-up population was itself selected on the basis of the tests.

(3) It is of paramount importance to secure the collaboration of the medical students. For this reason, if for no other, a clear undertaking must be given that individual records will be treated confidentially. No compulsion can be exercised on students to participate, and it seemed at first that there would be sampling difficulties, since volunteers for any investigation generally contain too high a proportion of the gifted and the energetic, whereas what is required is either a complete sample, a deliberately representative sample, or a random sample. In practice it has been found that the samples which are being obtained are very nearly complete. It is perhaps not too early to say that the willingness of medical students to submit to interviews and tests, administered by some "snooper" from outside, is a great tribute to their long-suffering.

(4) It was realised at the outset that to take examination results as the only criterion by which to judge success would be extremely misleading, and it is intended that the follow-up should not stop short at qualification. At that stage it is of even greater importance that the students, by then doctors, should be fully in sympathy with the aims of the inquiry. It is clear that the longer the follow-up can be extended the more useful it becomes, and the better the chance of assessing "success" or "failure" reliably.

Such an assessment is not an easy proposition. There is no single graduated measure which can be applied, and it is in the largest group of the profession, the general practitioners, that attainment is most difficult to gauge. But there can be little doubt that differences of proficiency are sufficiently recognisable to allow of a division into five or six groups in the way that Paget (1869) classified his students. It may be possible, by taking several defined and measurable criteria, to reach a still greater accuracy, but there is always a risk of allowing mathematical precision of treatment to outrun the biological content of the data. With the establishment of a compulsory period of a year's internship after passing the final examination, and before a licence is granted for independent practice, the task of estimating proficiency is likely to become easier in the first postgraduate year; however, time has still to be found for the legislation to effect this change.

Specialists present a different if somewhat easier problem—there are various milestones which succeed one another in the path of the intending specialist, and there are various honours which crown his progress. They may be unreliable guides in individual cases, but they do, on the whole, provide a recognised and workable hierarchy. The separation of those suited to specialist or research jobs from those suited to general practice may prove easier than the separation of "good" from "bad" practitioners in any particular category. It has already been suggested that it cannot be taken for granted in a time of change that the same qualities will always be required of doctors—curative and preventive medicine may call out very different qualities of mind—and in the interests both of the community and of the doctors it will be important to see that the students accepted are the right ones for the job they will have to do.

STATISTICS OF MEDICAL TRAINING

There is a further, as yet practically unexplored, field in connexion with the vital statistics of medical training. A pioneer study has come from Greenwood and Lewis-Faning (1937), who remark that "the statistics of medical graduation may be the starting-point of many curious inquiries." They examined, in the form of a life-table, the time taken from matriculation to qualification by 1254 Cambridge medical students. Greenwood and Teleky (1942), who carried the follow-up to twelve years, found that 15% had not qualified within this time, and that 33% of the total had taken over nine years from matriculation.

The figure of 12½% was accepted by the Interdepartmental Committee on Medical Schools (1944) as an estimate of the wastage-rate during training, but definite figures were available to them from only one medical school. Figures which I have seen from two other schools suggest that the rate is now sometimes rather higher. Accurate figures, however, can easily be obtai for the groups which are now being followed up in the M.R.C. investigation. Clearly differences in the wastage-rate may reflect important differences in methods of selection or training at different schools. It is a common experience in other occupations that, when reliable figures are obtained, wastage is found to be higher than had been expected. This is particularly true of an institution such as a medical school, where most of those who think about it have only a partial experience of the wastage—i.e., wastage during a particular year or two years of training.

A statistic which is more difficult to estimate is the selection ratio (ratio of applicants to available places). This problem is complicated by the number of those who apply to more than one school. (The appearance recently of duplicated letters among applications sent *to all the schools in turn*, with the name of the school typed at the top, is perhaps a danger signal.) Th there may be an increase in the number of applicati either because more people apply or because the same number of people make more applications; equally factor of multiple application may disguise a fall in number of applicants. As a part of the M.R.C. inves tion, information is being sought on the extent importance of multiple application. Twenty-six m schools have agreed to supply to the M.R.C. adv committee the necessary information for an analy be made.

CONCLUSION

What may be the upshot of a follow-up investig such as I have tried to sketch above? Fundament we are seeking to discover whether there are met either among those already in use or among those w may be devised or adapted for the purpose, which give a better than chance expectation of ch candidates likely to succeed in a medical career. To this it is necessary to evolve criteria of success which not of solely academic purport.

The practical problem, which has to be kept contin in mind, is that which today faces the selection comm in every medical school. As Lyon (1933) has said, "t have before them applications of two hundred, hundred, or four hundred students. They can perhaps, one hundred. If they have no basis at all prognosticating, the proper thing would be to all the names into a hat and draw out one hun It is to be hoped that in the future we shall have to echo his further remarks: "If they have dis methods of any value at all, they should use those to the best of their ability. . . . If prognostic c are good to the extent of even 25% in any combi we ought to use them. In fact, we must use the

TELLIGENCE TESTS AND UNIVERSITY CAREERS OF MEDICAL STUDENTS

Q. H. GIBSON
M.D., Ph.D. Belf.

PLYING the matrix test (Raven 1938) to second-year ical students Edholm and Gibson (1944) found that as of little value in predicting their performance hysiology examinations. Heim and Timpany (1944) ested that this result was due to the unsuitability e matrix test for application to a selected high-grade p. In spite of this justified criticism it seems worth rting the results of a follow-up of the students inally tested, since all have now completed at least years' study.

further group has been tested both with the matrix and with the Cattell scale III form A test (Cattell 4), which contrasts sharply with the matrix test in t it is largely verbal and is sufficiently difficult to ead the group over a considerable scale.

The tests were applied as described by Edholm and son (1944), and the follow-up data were obtained from official university records. The data are incomplete ause: (1) the tests were not taken until the second r and so do not include students who failed to complete first-year course; (2) the tests were not compulsory; (3) wastage of about 10% has occurred in the follow- owing to death, marriage, war service, and transfer other universities.

FOLLOW-UP OF UNIVERSITY CAREERS

uccesses in Relation to First M.B. Examination.— results for each of the years considered are shown arately in fig. 1. In this figure the total length he first column for each year represents the number students sitting the first M.B. examination. The pled columns show the numbers of students after h examination in the course who, having passed the t M.B. examination at their first attempt, have passed h subsequent examination with- failing in any up to the amination indicated. The ched columns give the same rmation for students who had or more attempts at the first examination. The difference veen the two groups is obvious: reas most students passing the M.B. examination at one mpt (stippled columns) proed directly to qualification, of those completing the mination piecemeal (hatched nns) failed again later in the e.

ilures in Relation to First Examination.—Table I s, for 1942 and 1943, the bution of failures per head e various examinations gh the course. In this table the students are divided into three groups according to the number of subjects passed in the first attempt at the first M.B. examination. Fig. 2 illustrates the growth of the cumulative totals of failures for the same groups, and again shows the striking difference between the group passing the first M.B. examination at the first attempt and those completing the examination by stages. Of students in group I only 2 (2·5%) have not yet qualified as against 21 (27%) in groups II and III.

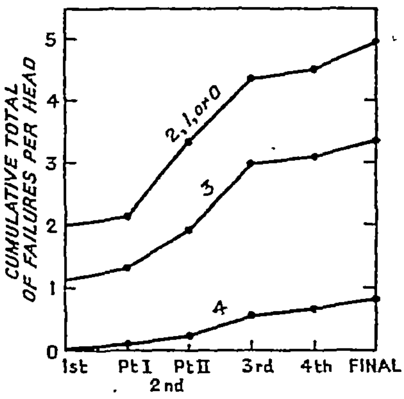

Fig. 2—Cumulative total of failures per head incurred by students having passed in the number of subjects shown in their first attempt at the first M.B. examination.

Preclinical and Clinical Results.—It is sometimes suggested that the preclinical years call for a set of qualities different from those required in clinical work, and that rigorous selection of students on the basis of results in the preclinical years would lead to the elimination of many potentially satisfactory clinical students. If this were so, a follow-up should reveal a tendency of this kind. Students were classified according to their records in the anatomy and physiology courses and their records in the clinical years. Table II indicates not only that the preclinical and clinical results are associated ($P = 0{\cdot}0001$) for each year, but also that there are very few students who, having failed in the preclinical years, then complete their clinical course without a check. It appears that special aptitude for clinical work is rarely divorced from ability to pass the preclinical examinations.

INTELLIGENCE TESTS

Matrix Tes and Clinical Examinations.—Edholm and Gibson (1944) have considered the relation between the matrix test and preclinical examinations; using the material obtained in the follow-up, it has been possible to extend this to the complete course. The results are summarised in table III. Though there was some degree of positive association in all cases, this was significant only for the preclinical years. The existence of positive association, however slight, in six independent instances nevertheless argues for some relation between the matrix test and the results of the clinical years taken as a whole.

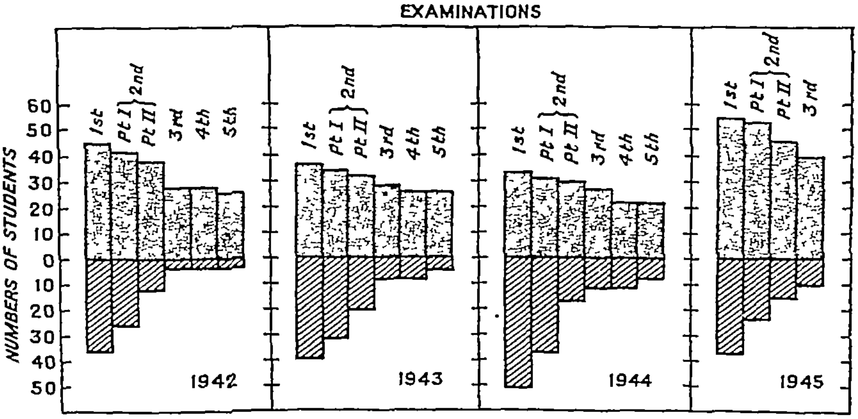

Fig. 1—Examination results: stippled columns, students who, having passed the first M.B. examination at the first attempt, passed the examinations indicated and all previous examinations at the first attempt; hatched columns, students who had more than one attempt at the first M.B. examination and then passed the examinations indicated and all previous examinations other than the first M.B. examination at the first attempt.

METHODS

Our test material can be divided into three main sections:

(1) Material usually obtained at interview: (*a*) family history; (*b*) academic background and achievement; and (*c*) general activities and interests. This material was obtained by questionnaires, and the resulting evidence appears to be as useful as the same evidence obtained by interview.

(2) Intelligence tests: (*a*) the Raven progressive matrices (20-min. version); and (*b*) the group test 33 of the National *Institute of Industrial Psychology*. *This latter test* was standardised on secondary-school children. It discriminates better between various levels of intelligence in the upper ranges.

TABLE I—INTELLIGENCE-TEST SCORES OF 40 MEDICAL STUDENTS

—	N.I.I.P. group test 33		Raven's progressive matrices (20 min.)	
	Average	Av. deviation	Average	Av. deviation
Men ..	146	12·0	49	4 6
Women	159	12 6	50	3 0

(3) More purely psychological tests: (*a*) a personality inventory of much the same type as the Mill Hill neurotic inventory described by Eysenck (1947); and (*b*) the "expanded" multiple-choice Rorschach test. We projected the Rorschach cards on to a screen. On a printed sheet were three sets of ten answers for each card. Students were asked to indicate which was their answer of choice in each set for each card in turn. This follows the technique described by Erickson and Steiner (1945).

The whole testing procedure occupied about 2½ hours. Our groups were small (4–12), but groups of 30–40 could be managed quite well.

RESULTS

The analysis of each set of questionnaires, plus the marking of intelligence tests and the multiple-choice Rorschach test, was a task where each of us had an allotted field. The clinical psychological material was marked by the psychologist, and the rest of the material was passed to the psychiatrist for final assay. A précis was made of all the material, at the end of which was written a short assessment of the candidate plus a grade. The gradings given were:

A. Definitely superior. Should get honours.
B. Definitely above average.
C. An average medical student.
D. Definitely below average but should eventually qualify.
E. Inadequate and unsuitable.

The final assessment of the material obtained is a subjective one in little way different from an assessment given after the usual interview. Interviewers vary greatly in their ability to assess personality. The psychiatrist is no magician, but his everyday job entails the assessment of personality and he should therefore be an adequate person to make a final assessment of the person interviewed. He tries to be objective but realises that his own personal bias will influence the results. He tries constantly to remove this error but he is not unaware of it. Some of the material we obtained can be expressed in figures (table I).

The women showed a significantly higher average of verbal intelligence. In fact, five of the women had a higher score than any of the men. This result was expected since, though half the applicants for entry to medical school are women, much less than half the acceptances are women. In other words, selection is more intense, and only women applicants who appear outstanding are accepted. These figures demonstrate that the interviewing panel manage to pick out the intelligent ones fairly well. Most interviewers agree that picking out the very superior is easy. Picking out the lower average type is much more difficult.

The lowest scores in each group are of interest since they give some indication of the lowest adequate level of intelligence needed for academic success. The four lowest scores for men were (group test 33) 107, 12 129, and 129. For women they were 124, 131, 140, and 145.

From our assessment we are inclined to feel that any score over 120 on group test 33 would indicate just adequate intellectual ability. This corresponds to an average secondary-school child and is probably equivalent to an I.Q. as low as 110. On the other hand, our results suggest that a minimum of about 135 would ensure much more adequate students. This level represents the 70th percentile of secondary-school children and an I.Q. of about 118. This figure has previously been reached by workers in this country and in U.S.A. as being the minimal adequate I.Q. for success in medicine.

Our final results were compared with similar gradings given by the senior administrative officer, who graded the students according to their academic success in the medical school. Table II shows the degree of agreement and disagreement between the gradings.

These tables show sufficient agreement for such small numbers to give us encouragement to continue.

We have made no comment on the value of the multiple-choice Rorschach test, because the numbers are small. All but one student gave adequate responses to this test. This student was rated D by us, but academically he was very nearly rated E, and there may be something of value in this test. This is a point we are investigating further.

CONCLUSION

So far the amount of testing we have done is inadequate for us to lay down any firm propositions, but we are encouraged. One point that interests us now is the result we shall get when we test large numbers of applicants. We feel we shall see a much wider scatter, and we hope to be able to show that screening can effectively and fairly reduce the number of applicants requiring to be interviewed. An important point not mentioned is how far academic success in medicine indicates a good doctor. Some of our disagreeme between academic success and our test ratings probably due to the fact that we were trying to as good future doctors and not necessarily those who w achieve academic success.

TABLE II—COMPARISON OF RESULTS OBTAINED BY DIFFE METHODS OF GRADING

Grading from test analysis	Grading on academic success					To
	A	B	C	D	E	
Men students A	—	—	—	—	—	[illegible]

E	—	—	—	—	—	[illegible]
Total ..	0	2	9	5	—	[illegible]

An example will explain the tables. Of eight men r C by test results, five were rated C and three D by aca results.

THE SELECTION OF MEDICAL STUDENTS

ASENATH PETRIE
B.Sc. Lond.
PSYCHOLOGIST, ST. GEORGE'S HOSPITAL, LONDON

THE Interdepartmental Committee on Medical Schools 1944) asked for further experimentation in methods of ing medical students. In this country Edholm ibson (1944) and Smyth (1946) have reported on ethods tried out in two medical schools. The eport did not hold out much promise for the further f the chosen tests for purposes of selection. The d report contained evidence of an encouraging tion in the number of failures by the use of a l battery of tests.

the United States Cowdery and Ewell (1931) and (1931, 1933) have shown that failures among al students can be predicted with a good deal of acy by the use of selection tests. They have shown these tests are superior to premedical grades in their tive capacity, and that the tests in combination premedical grades can predict 73% of subsequent es in examinations. The results of these investiga- were sufficiently promising to lead to the introduc- in 1931 of routine selection tests in all U.S. medical ols. Many of the schools count the marks resulting testing as a third of the total score given to a student; emaining two-thirds of the score is contributed by edical grading and the results of an interview.

the United States one of the main factors causing the sive investigation into selective tests for medical is was the need to reduce the failure-rate, which been as high as 20% in some institutions (Flack Begg (1928), in a survey of failures between 7 and 1926, showed the percentage to be fairly tant and to lie between 18% and 20%. Zapffe 33) reported a distinct decrease in students' failure- between 1931 and 1933, which is attributed by Flack 36) to the introduction of aptitude tests as one of the es of selection.

he need to select those who are most able to benefit a university education has become increasingly ent in this country with the rise in number of licants for such training. The ratio of applicants vacancies is particularly high in the medical schools. St. George's Hospital Medical School, for example, he six months from October, 1947, to March, 1948, e were 270 applicants for the 30 places available; there are indications that the situation is similar ome other medical schools (Smyth 1946).

n most medical schools, in the absence of predictive s, the selection is made on the basis of premedical des and interviews. There is a real danger in relying premedical records. This was pointed out by Moss 31), who, after a careful survey of the problem, stated t premedical grades were not a sufficiently fine riminative guide, and therefore there was a likeli- d of turning down very good men to make way for liocre students. The introduction of intelligence s, in addition to the scrutiny of premedical grades, lers such mistaken decisions much less probable— a measure of intelligence, as distinct from one of evement, provides crucial information.

knowledge of the student's potential intellectual ty and past achievement, however, is not enough, personality, even if it is not so accurately measur- as intelligence, contributes a great deal to the tiveness of the student and the doctor. Thus, in of the introduction of routine testing in the U.S. cal schools, there still appear to be failures among nts of high intelligence, which have caused serious rn to at least one university. Waggoner and r (1946), at the University of Michigan, reported on an examination of medical students by means of the Rorschach test and a psychiatric interview:

> "Among students with even very high I.Q.'s, a relatively minor maladjustment occasionally resulted in academic difficulties. . . . On the other hand, it appeared that strong motivation and good adjustment could often compensate for an I.Q. which under average circumstances would be considered inadequate."

Their conclusion that there is need to take into account other aspects than the ability of an individual student is supported by two earlier investigations of university students. White (1931, 1932) compared "discrepant failures" with "discrepant successes" of students of the same intelligence. The former were found to be more frequent in students handicapped by mental disabilities of the anxiety type. Neel and Mathews (1935) showed that the "non-achievers"—those of high intelligence whose grading did not reach expected level—more often experienced conflicts about religion and life in general than did the "achievers." It is clear that measures of maladjustment would form valuable additions to tests of ability in the selection of students.

With this problem in mind a study was carried out on the students in St. George's Hospital Medical School in 1947–48. An attempt was made to select a group of tests which, in conjunction with school record and interview results, would indicate ability to pursue a medical course successfully, and might be used in selecting students for admission to the medical school. The present investigation, in addition to measures of intelligence designed for the more gifted of the population, included measures of personality maladjustment or neuroticism.

The prevalent use of only one type of intelligence test has been criticised (Treddick 1942) on the grounds that such measures are likely to be less diagnostic than are several tests measuring different abilities. The ability tests included in this investigation were chosen to meet this need.

The subjects consisted of 49 men and 8 women students of St. George's Hospital Medical School with a mean age of 24·37 ± S.D. 4·35. The average age was relatively high because of the many ex-Servicemen in the school in 1947–48.

All the intelligence tests show small negative correlation with age—i.e., there was a slight tendency for the older students to do less well on the tests than did the younger ones. These negative correlations seem to bear out the opinion of the teachers in medical schools that the older student has additional difficulties in his course when compared with the younger.

INTELLIGENCE TESTS

It was necessary to use intelligence tests which differentiate well between persons of high intelligence, since university students are to be found at the upper end of the distribution curve of intelligence. Vernon (1939) and other authorities have reported an average I.Q. of 126 for university students. Besides the higher level of intelligence among students, the range of intelligence among them is smaller, a fact which emphasises the need for the test to discriminate well at the higher levels of ability. Edholm and Gibson (1944) have shown that unsatisfactory results are obtained when tests are used which are not intended to discriminate among those of very high intelligence.

Himmelweit (1948) has carried out an inquiry into suitable intelligence and personality tests for the selection of students at a college of a university. She used, in her investigation on several hundred students, tests of general intelligence and tests which, besides general intelligence, measured group factors, such as verbal and memory factors. Out of this battery those tests which appeared to be most promising and to be most closely related to the special abilities required of medical

Matrix and Cattell Tests.—A total of 95 students completed both tests. The results for the Cattell test were converted into I.Q. figures according to the standardisation given by the author (Cattell 1934). The matrix test was applied as described by Edholm and Gibson (1944) with a 20 min. time limit. The results were: matrix test, mean 47·4, median 48, standard deviation 6·4; Cattell test, mean 139·3, median 140, standard deviation 11·0. The coefficient of correlation, $r = +0{\cdot}30$, though highly significant, is surprisingly low, suggesting that the two tests are measuring substantially different quantities. When correlated with physiology-class examination marks, the Cattell test gave $r = +0{\cdot}325$, whereas the matrix test gave $r = +0{\cdot}249$. Neither of these values is strikingly different from the correlations found by Edholm and Gibson between the matrix test and physiology-class examination marks in previous years.

TABLE I—SUBSEQUENT FAILURES IN RELATION TO FIRST M.B. EXAMINATION

Group	No. of subjects passed in first attempt at first M.B. exam.	No. of failures per head						No. of students
		First M.B. exam.	Second M.B. exam.		Third M.B. exam.	Fourth M.B. exam.	Final exam.	
			Part I	Part II				
I	4	—	0·06	0·14	0·36	0 09	0·15	80
II	3	1·15	0·16	0·59	1·10	0·12	0·48	39
III	2, 1, or 0	1·70	0·42	1·23	1 00	0·15	0·45	40

The students tested have now completed the course except for the final M.B. examination, and 91 have been successfully followed up. Some idea of the relative predictive value of the tests may be obtained by noting the numbers of failures incurred by students grouped according to their test performances (table IV). Both tests are negatively associated with the numbers of failures in the different groups. The association is highly significant for the Cattell test, but the value for the matrix test is not significant.

DISCUSSION

The results of the follow-up have substantially confirmed the earlier conclusion of Edholm and Gibson (1944) that the matrix test does not possess any great value in predicting examination results. The Cattell test, though different in form and only slightly correlated with the matrix test, does not appear to be much better. The results suggest that little can be done towards the problem of student selection by means of standard commercially available intelligence tests, except that students with notably low scores might usefully be eliminated. For example, if correct solution of 41 problems in the matrix test in 20 min., or of 46 problems in unlimited time, had been made an arbitrary requirement for admission, 49 students would have been rejected from the four years considered. Of these 49 only 7 have clear records at the university. If the test had been applied at the end of the first year, and a reprieve allowed to those with a clear university record at that time, 3? would have been rejected, all of whom have, in the event, had chequered careers.

TABLE II—NUMBERS OF STUDENTS CLASSIFIED ACCORDING TO THEIR PERFORMANCE IN SECOND M.B. AND IN LATER CLINICAL EXAMINATIONS

Year	Pass clinical, pass second	Pass clinical, fail second	Fail clinical, pass second	Fail clinical, fail second
1942	29	2	23	22
1943	33	3	18	18
1944	29	5	16	23

TABLE III—ASSOCIATION BETWEEN MATRIX TEST AND EXAMINATION RESULTS

Examination	Probability of independence		
	1942	1943	1944
1st M.B. ..	0 029	0 024	0·0009
2nd M.B. ..	0 30	0·016	0·0077
3rd M.B. .	0·38	0 50	0 53
Final	0·14	0·35	0 70

The attributes examined were (1) obtaining a score in the matr test equal to or greater than the median score and (2) passing the examination indicated at the first attempt.

On the other hand, the follow-up has shown that th is a striking consistency in the performance of t individual student, the pattern of whose career is of foreshadowed by the results at the end of the first ye The close association between the results in clinical a preclinical years suggests that it might well be profita to proceed by admitting a number of students somewh in excess of the capacity of the clinical departments, a rejecting with rigour at the end of the first and seco years. In theory, at least, such a scheme would reduce the proportion of "chronic" students.

In practice the results might well be less satisfactory, since intensive "cramming" for the first-year subjects would be encouraged. If an intelligence test were included in the programme for selection, even with due care ensure that its contents remained secret, its gen nature would gradually become known, and instruct in the design of the test and in the most profita approach to its problems might become available.

TABLE IV—RELATION OF MATRIX AND CATTELL TESTS TO EXAMINATION RESULTS

Matrix test score	No. of students	No. of failures	Cattell test score	No of students	No. of failures
52–60	27	30	147–	27	18
46–51	34	44	135–146	35	53
0–45	30	46	0–134	29	49
Probability of independence P = 0·45			Probability of independence P = 0 0017		

This survey is concerned with examination res and the conclusions drawn from it depend on the vali of such results as an index of future performance. The relation between academic success and effective pro fessional service to the community, however, is no known and appears to be most difficult to assess.

SUMMARY

The university careers of second-year medical stude taking the matrix test in 1942, 1943, and 1944 have followed up.

The relation between the test and examination r is slight.

The careers of individual students were remar consistent throughout the whole course.

The Cattell test, correlating only slightly with matrix test, and different in form, gave essent similar results.

Raven, J. C. (1938) Progressive Matrices. London.

The judgments on which our criterion was based were made by doctors, several of whom are examiners at the qualifying medical examinations. They also included, as mentioned above, doctors who choose the successful candidates for the much-coveted house jobs.

It is not recommended that the valuable criteria already in use should be superseded by these tests alone. It is desirable, however, to have available all the possible measures of ability and personality before selecting the 10% or even 50% of applicants for whom there are places.

A fear has been expressed by some authorities that these selection methods might exclude some really good students. It is undoubtedly true that test methods of selection will probably exclude some good people; the point to decide is which method will exclude least. The data presented should make it clear that, whether the problem is viewed from the aspect of reduction of failures or the increase in the proportion of really outstanding students, the inclusion of selection tests of the type described can be of great assistance. This assistance at the expense of three hours' testing is not a great deal ask from even overworked medical students.

The results so far available† justify further research ith the tests used and for the selection of students in edical schools. The predictive value is likely to be creased by the further development of the personality sts in the battery. The information obtained as a sult of such testing could be used in addition to pre-edical rating and interview rating as a basis for the ceptance of students and their later guidance.‡

SUMMARY

The intelligence of 57 students at St. George's Hospital edical School was tested with seven verbal and non-rbal tests standardised on people of high intelligence. ree measures of personality were also used. By eans of individual ratings by two of the senior staff ost closely connected with each student, information as obtained on each student's medical standing. A ultiple correlation of 0·63 was found between the iterion and seven of the above measures. The reliability f the criterion was 0·80.

At the present ratio of selection in this hospital (1 in 10) e number of successful students could be increased from 0% as at present to 99%, and the proportion of out-anding students from 10% as at present to 39%.

I am indebted to Dr. Desmond Curran, physician charge of the psychiatric department, for suggesting is investigation and for his active encouragement. The k was made possible by the kind coöperation of the dean, r. M. F. Nicholls, his staff, and the students of the medical hool.

he results of the qualifying examinations, as they become available, will be used later as an additional criterion.

nce this investigation was experimental, the results obtained in each student are confidential and unknown to the authorities and teachers of the school.

PERSONALITY STUDIES OF MEDICAL STUDENTS

W. M. MILLAR
M.D. Edin., D.Psych.
SENIOR LECTURER IN MENTAL HEALTH, UNIVERSITY OF ABERDEEN

THE selection of leaders in the Army during the war has attracted widespread interest. It may seem incongruous that a technique fashioned within a disciplined community at war should be in any way applicable to the problems of a free society at peace, but already selection has been adopted by many organisations in civil life. Among those that have applied the principles of the War Office Selection Board (W.O.S.B.) are the Civil Service, the Indian Civil Service, the Palestine Police, the late National Fire Service, and armies of Allied countries.

No full account of officer selection and its results has so far been published. Rees (1945) refers to the subject in connexion with war psychiatry. Gillman (1947) has described the test procedures and the composition of a W.O.S.B. An Expert Committee (1947) has published a report which is mainly concerned with the selection work done by psychologists and psychiatrists in the Services. The only contribution to the theory of selection has been made by Gibb (1947), whose views on leadership are based on his experience of officer selection in the Australian army.

Recommendations have been made for the introduction of selection into medicine by the Interdepartmental (Goodenough) Committee (1944), the *British Medical Journal* (1946), and others. Some medical schools have begun to select applicants by means of intelligence, aptitude, and other tests (Smyth 1946, Wilkie 1946), and the Medical Research Council have sponsored research in several London and provincial schools.

Before considering its application to medicine, I shall give a brief account of the aims, theories, and methods of officer selection.

Selection of Officers in the British Army

Scientific methods of selecting officers were first introduced into the Army in 1941. The first experiments were stimulated by the fact that the German army had been using selection since 1926, and by the urgent need for officers created by the rapid growth of a citizen army and by the losses at Dunkirk. Traditional methods—based on rule of thumb, and efficient within the small class from which the pre-war regular officer was drawn—proved incapable of dealing with war-time candidates coming from every social class and representing an infinite variety of personality. Whereas, before the war, it was relevant to ask a candidate to what school he had gone and what his private income was, these questions were now not only useless but also objectionable. Indeed, they were so much the cause of dissent and dissatisfaction among candidates that in 1941 suitable men were refusing to apply for commissions. A radical change was therefore imperative, and it is noteworthy that the initiative for this change came from senior regular officers, who enlisted the aid of psychologists and psychiatrists in a joint trial of an entirely new method.

The experiments were carried out on several groups of officers attending a six-week course for company-commanders. These officers were given an intelligence test, an interview by a psychiatrist, and aptitude tests based on the German model. Results of these assessments were compared with reports by instructors, and in 85–90% of cases there was complete or substantial agreement between the two judgments. A provisional board was set up in January, 1942, to continue the students were selected. The tests used were adaptations of current American intelligence tests. They included one test of Thorndike's (1925) completion, arithmetic, verbal, and directive battery (C.A.V.D.)—namely, the C or sentence-completion test. Cowdery and Ewell (1931) have reported a high correlation between the C.A.V.D. battery and medical-school grades. The other tests, which were adaptations of some of Thurstone's (1938) primary ability tests, were tests of vocabulary, verbal classification, memory, fluency, non-verbal intelligence, and spatial perception. The test of spatial perception was included on the assumption that the problems confronting the medical student in anatomy required particularly good spatial visualisation.

MEASURES OF PERSONALITY

Neuroticism.—The two tests of neuroticism used were the Maudsley medical questionnaire (Eysenck 1947) and the Maudsley word-connexion test (Crown 1947). These two measures of maladjustment have been shown, on extensive investigations reported by these writers, to differentiate well between the neurotic and non-neurotic population. The tests were included in the belief that neuroticism was one of the major personality factors which would reduce the effectiveness of a student.

Tendency towards accuracy has been found to be positively correlated with success in examinations when intelligence was held constant (Himmelweit 1948). To reach the index of inaccuracy, the number of false answers given in all the tests except those of neuroticism and fluency was calculated, and expressed as a ratio of the total number of answers attempted in these tests. The index of inaccuracy was found to be positively correlated with both the Maudsley medical inventory (+ 0·40) and with the Maudsley word-connexion test (+ 0·43). This suggests that the more neurotic students tend to make a relatively large number of mistakes. The total testing session took three hours.

CRITERION OF PREDICTIVE VALUE OF TESTS

Two independent judges were chosen by the dean from among his senior staff as knowing most about each student. These judges rated the students, as regards their medical ability, on a five-point scale, ranging from very good to very poor. The considered judgment of two senior physicians, based on the working record of the student, has certain distinct advantages over examination results. Apart from examination not being an entirely satisfactory assessment of a student's all-round clinical ability, it is the opinion of the senior medical staff which determines which of the students is appointed to resident posts. The combined rating had a reliability of 0·80.

RESULTS

The correlations were worked out between each of the nine tests and the combined rating of the judges, and were as follows:

	Correlation
Word-connexion	−0·08
Vocabular	0·42
Classification	0·41
Rote memory	−0·11
Sentence completion	0·30
Fluency	0 20
Decoding	0·35
Form perception	0·39
Maudsley inventory	−0·16
Index of inaccuracy	−0·27

EXPECTED PROPORTION OF STUDENTS SELECTED WITH HELP OF TESTS WHO WILL BE SATISFACTORY

Selection ratio	Percentage considered satisfactory before use of selection tests*							
	90	80	70	60	50	40	30	20
0·10 (1 in 10) ..	100	99	97	94	90	83	74	60
0 20 (2 in 10) ..	99	98	95	90	84	75	61	50
0·30 (3 in 10) ..	99	96	92	87	79	69	58	43
0·40 (4 in 10) ..	99	95	90	83	75	64	52	38
0·50 (5 in 10) ..	98	94	87	80	70	60	47	31

* The figures in the table are derived from Taylor and R (1939).

A multiple correlation of all the tests except sente completion and the word-connexion list with the criteri was calculated, and the multiple R was found to 0·63.

The reduction of failures and the increase in succe to be expected from the use of these tests are sho in the accompanying table. The correlation of 0 is the basis throughout. This table presents the p portion of satisfactory students who could be selec with the help of these tests under various conditio *Along the vertical axis are indicated* the selection ra which may prevail at different schools—i.e., the p portion of places to applicants. Along the horizont axis are placed the percentage of students who are present considered satisfactory. In the body of the table are shown the percentages of students selected with the help of the tests who would be satisfactory, given certain selection ratios (set out on the left of the table), and given a certain percentage considered satisfactory before the introduction of tests (set out at the top of the table).

In this hospital 82% of the students were rated being satisfactory. The selection ratio as reported above is less than 0·10—i.e., 1 in 10 is chosen—and glance at the table will show that the percentage satisfactory students who could be selected with the of the tests is 99—i.e., the failures could be reduced 18% to 1%.

Alternatively one can consider the table from the vie point of those students rated "very good." were about 10% in this hospital belonging to the supe group. The selection ratio is again 0·10. The verti column of figures under 10% shows that with the of the tests we could have selected not 10% but 3 of very good students. But, even if the selection r should increase, and as many as 5 students out of applicants be chosen, the use of the tests would incre the number of very good students from 10% to 18%.

DISCUSSION

The results shown in this group indicate a high pr dictive value for the tests. External factors affecti medical work have not been studied—for example, th need to earn during college years, worries of various kind and family responsibilities must influence the student efficiency considerably. It is hoped, however, th further development of the measures of personality in th battery will indicate the ability of the student to co with such stresses.

The tests do not guarantee that those passing the will be successful, but they do ensure that they hav the ability to succeed if outside circumstances are favo able. It is recognised that the capacity to pass exami tions is not the hallmark of a good doctor, but it is c that a student will never get the chance to show wh *he is a good or poor doctor* unless he *passes examinati* There is a great need for much more investigation i what constitutes the good doctor, besides what constitut the good medical student.

---

* All correlations are calculated by the product moment formula and have been corrected for attenuation in the criterion by Dunlap and Cureton's (1930) formula. The multiple correlation given below, in view of the small number of students tested, is probably a slight overestimation of the true correlation due to the well-known *tendency of the multiple correlations* formula to summate errors; but none of the conclusions are likely to be affected to a considerable extent. This is borne out by the fact that similar intercorrelations between the tests were obtained in other university groups where much larger numbers had been included.

tio has steadily increased since the end of the orld war, and after a plateau during the second s again risen steeply. Smyth (1946), who has ed the causes of this rise, concludes that it will ne for an indefinite period. The financial barrier licine having been largely removed, the profession open to anyone who has interest and competence. t methods of selection are proving inadequate, is is due both to the greater numbers and to the greater variety of applicants. The situation is in arallel to the situation in the Army in the early s of the war, and we may draw the same conclusion the older methods will soon show themselves as ded and unfair. Preferences for special types of nt will be seized on as examples of class prejudice, e same "atrocity stories" as circulated about old ds of officer selection will be heard in relation to ations for medicine.

at is therefore needed is a method of selection which pe with the large numbers and can at the same time ith the more complex issues of personality assess- No other method has so far been so well proved highly developed as that of officer selection. And, ering that W.O.S.B. dealt with a similar kind of ion problem in the young adult, the method bed seems applicable. Indeed, the special work d out in selecting schoolboys for six-month univer- ourses (CUBS) and for two-year engineering cadet- (CUBES) was highly relevant to the selection of al students.

Need for Research

fore scientific selection was introduced into the y, there was a period of preliminary research. opriate tests were devised and examined for relia- and validity. Details of an optimum programme of ng were worked out. Decisions were reached about proper composition of the board. Administrative ainery was set up. In addition, the undertaking was ly publicised, so that it could quickly and easily to the Army scene. The same kind of approach will eeded when selection is introduced into medicine. ntroduce a ready-made procedure in its entirety d be a gross error, and would violate the principle a selection scheme should be evolved from in and should be adjusted to serve its special ose.

Aberdeen such a period of research is envisaged by department of mental health. Though the bulk of work will be done by members of the department, uding a research fellow, it is an essential part of the eme that other members of the staff coöperate various ways. We also hope to maintain close son with the Medical Research Council, who are nsoring a parallel scheme of research in other dical schools.

The aim of the experiment is to gain as much relevant ormation about each first-year student as possible, l to follow him up throughout his undergraduate eer. So that the data obtained shall be comprehensive, students will be strongly urged to submit themselves untarily to the testing procedures. These procedures e still to be worked out in detail, but will be based on .S.B. principles. They will include written tests to vide basic information—intelligence tests, general- wledge tests, biographical and attitudinal question- res, and psychological tests, mainly of the rojection" type, such as the Rorschach test. Reports headmasters and examination results will also be used. erviews, carried out by members of the department of ntal health and possibly others conducted by members other departments, will be an important section of the cedure. But it is expected that much valuable and information will be elicited by means of group tests on the "leaderless group" model of Bion. In the essentially human profession of medicine it is of paramount importance that the doctor should be able to put his knowledge into everyday practice with his patients. At present no attention is paid to this aspect of a doctor's make-up. It is hoped that, by observing the student as a group member, some light will be thrown on the subject.

Having gained information about the student by these means, it will then be necessary to check the findings against certain criteria. First, it will have to be established that the methods are reliable and consistent. Secondly, the results will be compared with the student's performance in examinations. Thirdly, they will be compared with the personal opinions of students provided by the teaching staff. Finally, in the distant future, it may be possible to follow up the student's career as a doctor, at least for the first year as a houseman—and perhaps beyond.

At the same time an investigation will be made into the nature of the doctor's job. Such a job analysis, which has not yet been attempted, will be a major task, extending far beyond the scope of the present scheme. But a beginning should be made.

One of the most promising lines of inquiry would be into the causes of failure among students.

Waggoner and Zeigler (1946) have drawn attention to this point in a study of 135 failing students at an American university, comparing their performances in various intelligence and psychological tests with those of the successful students. They found that no one test has predictive value, though they think that low intelligence is certainly one factor, and that an intelligence quotient (Binet standard) of less than 130 is a severe handicap to any student, both in medical school and after graduation. Their results suggest that a psychiatric interview, a Rorschach test, and "certain selected psychological studies properly interpreted" would give the information needed for a workable system of selection. So far as can be inferred, however, their tests are of the laboratory type, and no detailed follow-up scheme was carried out. The standard against which they measured success or failure was the examination, which in our present state of knowledge seems of doubtful value.

Objections to the Scheme

After working out a method of selection which is fair, simple, reliable, and valid, there will remain the formidable task of getting it accepted by those concerned—the university, other educational bodies, the applicants, and (not least) the parents of the applicants. Resistance to "scientific" selection would take the form of traditional opposition to any new procedure, and would be coloured by current attitudes towards psychology itself. The first set of resistances need not concern us; for, if there is any value in the new system, it will find its champions. But, because the extension of psychology is viewed with distrust by many informed and earnest thinkers, it may be worth considering the nature of this conflict.

The most consistently voiced objections to modern psychology—especially that of Freud—are that it derives from an impersonal and determinist philosophy, that the doctrine of the unconscious would make of man and his will nothing more than the product of blind chance (or, at least, that man's conscious efforts in deciding his own fate are impotent), and that psycho-analysis (as with all other types of analysis) is always destructive and moving away from truth rather than towards it. The spirit and soul of man, under the critical analysis of modern psychology, disappear; and man is reduced to the level of the animals, with no unique place in the universe. This "sunless philosophy," it is contended, is the very negation of personality, and therefore cannot make any contribution to the study of personality. The objection therefore is that the essential uniqueness of the individual, and the fact that individual personality is experiment, and the first working boards were started in May of the same year.

BOARD STRUCTURE

Each board was presided over by a regular colonel, who was solely responsible for acceptance or rejection. In reaching his decisions the president was helped by a team of workers including a deputy-president (lieut.-colonel), three military testing officers (major and captains), a psychiatrist, and a psychologist. There were also technical and administrative assistants. Each board was therefore a small self-contained unit, and each member a whole-time worker in it. This gave selection a professional status and made for high technical standards. The rôle of the experts was twofold: firstly they were ordinary members of the team, on an equal footing with other members, in giving their opinion; and secondly they acted as expert advisers to the president on technical development. These experts were viewed with suspicion only by those who had no direct acquaintance with their work. When it was discovered by their colleagues, in daily contact with them, that there was no "flowing robe and crystal ball," they were treated as the ordinary human beings they undoubtedly were.

TEST PROCEDURES

The candidates came to the board for three days, in groups varying in number from 60 in the early days to 24 finally. On the first day there were written tests: intelligence tests, questionnaires, and psychological "projection" tests (word-association test and Murray's thematic apperception test). On the remaining days there were interviews by the president or the deputy president and by the psychiatrist or the psychologist, and individual and group tests conducted by the military testing officers.

The interviews were biographical—i.e., concerned with the full life-history of the candidate. The president dealt with school, work, and Army records, and inquired about hobbies and interests; the psychiatrist or the psychologist went into the earlier history and the family history. Matters of physical and mental stability were also explored. Little importance was attached to the impression that the candidate gave as compared with the information he furnished about his life-history. Newcomers to interview technique tend to suppose that the impression given is the most important thing, and rely for their judgments on what was called in W.O.S.B. circles the "magic-eye technique."

Though the word "test" has been used to denote various methods of assessment, it is here used with regret, for want of a better. Most of the procedures are not tests in the usual sense, but real-life (or near real-life) situations which serve as "occasions" for the observation of behaviour. For example, the series of tests known as the "basic series" and originated by Bion (1946) were designed for small groups of 6–8 candidates, and took the form of discussions, planning projects, group tasks, and games. The groups had no set form, were leaderless, and had no rules of procedure to guide them. The aim was that each candidate should be given the chance to behave in the manner most true to his own nature. In the practical task, for instance, the group was asked, as a group, to do a simple job, such as moving a heavy object over a supposedly electrified fence, using only the few "props" provided on the site. The *apparent* task was to finish the job as quickly and dexterously as possible. The *real* task presented to the candidate was to cope with the other members of the group and, at the same time, further his own chances of obtaining a commission. The "test" was therefore a study in interpersonal relationships.

THE FINAL CONFERENCE

At a final conference each candidate was reported on at length by each member of the board, and an attempt was made to piece together all the evidence, to get an over-all picture or "profile." It was only when an agreed "profile" had been fashioned that the final decision, to pass or to fail, was made by the president. This final integration of evidence was in itself a significant social phenomenon, since it implied team-work of a high order, with tolerance and understanding on the part of members to reach agreement. It was as necessary for each member to know himself and his colleagues, their prejudices and scotomata, as it was to know the candidate. And it was vital to the success of the work that each member was as alive to the implications of good contact in his own group as in the candidate group.

It was the aim of the board to get to know as much as possible in the time available about the candidate as a unique person, and then, on the basis of this intimate and comprehensive knowledge, to decide whether his particular personality was likely or not to develop with training into a good officer. There was no theoretical bar to any type of person, were he manual worker or university graduate, provided it was thought that he could do an officer's job, in his own way, successfully.

ASSESSMENTS OF CONFORMITY AND STYLE

The approach to the problem of assessment in the method just described differs from that current in the educational world. This difference may be brought out in the following illustration:

> A pupil has just sat his examination, say in history. His answers are typewritten and then given to someone who knows him well—perhaps his mother. The chances are that she will find difficulty in recognising it as the work of her son. The more successful he is in his answers, the more will they conform to some ideal standard set by his teacher—and the less will his individual efforts be apparent to his mother. Personality is therefore obscured by the achievement of conformity. On the other hand, if he is asked to write freely on any subject in an essay, his uniqueness, or style, will at once become apparent.

In W.O.S.B., as time went on, assessments of style gained more favour and those of conformity less, until a balance was struck. The candidate was encouraged to come out from behind his mask of regimentalism and to r himself as a true person; and it was in the group tests, so brilliantly conceived by Bion, this opportunity was afforded. Observation of spontaneous behaviour of different persons, in a so as against a laboratory setting, was one of the principles of officer selection.

RESULTS OF OFFICER SELECTION

Several follow-up studies were made, successful candidates being followed up at officer cadet training (O.C.T.U.) and later on active service. On the whole, the elaborate procedure of selection was amply justified the quality of officers improved and there was much less wastage at O.C.T.U.

Because the method was so obviously fair and thorough it encouraged men to apply, with the result that supply kept up with demand. Further, much of the information obtained about the individual soldier was put to good use in many ways other than selection. Training methods at O.C.T.U. directly benefited, and new light was thrown on problems of morale and man-management by the researches into the behaviour of groups.

Applications to Medical Education

The experience gained in officer selection can, I suggest, be applied to medical education in three ways—selection, in counselling, and in training.

SELECTION OF MEDICAL STUDENTS

In almost every medical school there are many more (in some cases many times more) applicants than pl evidence would be afforded that the educational aim of the university is as much to further the interests of the student in his pursuit of learning as it is to provide the community with a good product.

CONTRIBUTION TO TRAINING

The modification of training to meet individual needs is a cardinal principle of education, albeit one which is receding before the ever-increasing size of classes and the diminishing ratio of teachers to students. But it is possible that this principle may yet be observed. It is clearly impossible for *all* teachers to know *all* students intimately, but it seems not only possible but very desirable for *some* teachers to know all students intimately. This would happen in a comprehensive selection and counselling service. Much valuable information about the students would be available for all teachers.

It is also possible that information gained about the behaviour of small groups can be applied to the method of teaching. At present the student is taught as a unit in a large class, and mainly on the basis of interpersonal rivalry and competition. Perhaps this method of teaching brings the more antisocial self-seeking "thruster" to the top, whereas it seems more desirable to foster the individual with good contact. It remains to be seen whether the small group can act as the ideal unit of teaching, and whether an awareness of social need is not a greater stimulus to learning than is the personal desire for academic honours.

Since research into selection is essentially an assessment procedure, perhaps some additional methods of assessment throughout the student's undergraduate career may be grafted on the existing examination system, which is known to have its defects.

Conclusions

Advances in the study of personality having been made in many other fields, particularly in the selection of officers in the Army, there is a challenge to the universities to continue the work.

New methods of selection of medical students are urgently needed, and this seems to be the best starting-point for further research.

Because of the social and technical difficulties involved, at least three years' experiment will be needed before a routine procedure of selection is adopted.

It is hoped that this study will contribute information that can be applied to the guidance of students in their undergraduate years and towards their future in the different branches of medicine. Contributions may also be made to methods of training, particularly in the employment of small groups as teaching units wherein motives of rivalry are replaced by those of coöperation as a basis of learning.

My thanks are due to Prof. D. R. MacCalman for valuable advice and criticism.

Reviews of Books

Widening Horizons in Medical Education

(*A Study of the Teaching of Social and Environmental Factors in Medicine 1945–46.*) Report of the joint committee of the Association of American Medical Colleges and the American Association of Medical Social Workers. New York: Commonwealth Fund. 1948. Pp. 228. $2·75.

How far are the disciplines of the medical schools developing the sociomedical approach in students? The mere technique of training them to relate disease, as seen in the wards, to social and environmental influences is still far from perfect. The joint committee responsible for this report has examined teaching in a large number of American and Canadian medical schools, and paints a varied picture of its findings. Clearly many more experiments have been tried in America than in Britain; but though some date back longer than any of ours, many are still in tentative early stages, and are neither well received nor suitably dovetailed into the curriculum as a whole. But there are some notable exceptions, where clinical teacher and medical social worker act in harmony, and the student gets the chance of seeing good medical social work, undertaking case-work, and making home visits, so getting to know the patient and his family over a long time. At worst, he gets the advice that "certain local organisations exist which the patient may contact"—a dismal travesty of the teaching of social medicine. Sociomedical teaching is sometimes carried out by the clinical departments, sometimes by the department of hygiene and public health.

The report is concerned almost entirely with social medicine as it applies to the sick person and his family: an extension of diagnosis and care for which the medical social worker is responsible; and indeed the last chapter in the report—on the rôle of the social worker in medical treatment—is the best.

In the U.S.A. the current idea of social medicine still centres in the care and aftercare of the hospital patient, and the costs of such care, and thus reflects the prevailing individualism of America culture. The report, though dealing specifically with social and environmental factors, has little to say of the bearing of social medicine and pathology on the community as a whole or on selected groups. Inevitably, then, teaching is incomplete, and studies are confined to attempts to repair damage which is often far advanced, and which is in itself evidence of a failure in social medicine. Sickness in the individual and the family again and again reflects wider problems of disease which can be examined more rewardingly by complementary statistical studies—medical, social, environmental, and occupational—and by more intimate investigations of people's response to work and economic opportunity. These throw light on the origins of diseases and suggest ways of reducing or preventing them. The narrower American approach is perhaps reflected in some rather diffuse social case-reports by students, quoted in the text. As the writers of the report themselves suggest, the findings of social medicine, like those of clinical medicine, need to be accurately presented and interpreted with judgment.

Cardiovascular Studies

K. J. FRANKLIN, D.M., F.R.C.P., professor of physiology, St. Bartholomew's Medical College, London. Oxford: Blackwell Scientific Publications. 1948. Pp. 306. 42*s*.

WE hear much nowadays about the synoptic approach to teaching, but it is usually taken for granted that research implies specialisation; indeed, many research-workers would lift an eyebrow if they were asked to be a little more synoptic in their approach to the unknown. Not once, but several times, Professor Franklin, either alone or as a member of a team, has given us works which may have owed their inception to interest in a technique, but which in their maturity display the subject under review in the broadest possible light. Its history is carefully recorded, and no distinction is recognised between anatomy and physiology; evidence of every kind is given its full weight. The present book is about the eustachian valve and the intervenous tubercle of an end in itself (and not simply a means or a product), are not respected.

There are also critics within the psychological camp. Bertocci (1946) says:

> "The inviting 'mask' of personality has indeed brought many suitors, in the name of common-sense, the arts, religion, philosophy, biology, mathematics, sociology, physics and, finally, 'scientific methodology.' But none of the suitors has won her, for they have sought to ensnare her by their formulæ rather than respect her for her many-sided 'uniqueness.'"

This uniqueness of personality is also referred to by Sherrington (1947):

> "This self is a unity. The continuity of its presence in time, sometimes hardly broken by sleep, its inalienable 'interiority' in (sensual) space, its consistency of viewpoint, the privacy of its experience, combine to give it status as a unique existence. Although multiple aspects characterise it, it has self-cohesion. It regards itself as one, others treat it as one. It is addressed as one, by a name to which it answers. The Law and the State schedule it as one. It and they identify it with a body which is considered by it and them to belong to it integrally. In short, unchallenged and unargued, conviction assumes it to be one. The logic of grammar endorses this by a pronoun in the singular. All its diversity is merged in oneness."

Bertocci also says:

> ". . . the central feature of personality is the knowing-wanting *unitas multiplex*. The personality is not the product of an ambiguous field of forces, but represents what a given unique self has created out of the forces and opportunities open to it in its *rapport* with the world."

It seems clear that these views will have to be endorsed by those carrying out any investigation of personality; and, though the individual may become the object of minute and unprecedented scrutiny, it should be recognised that he does not thereby lose his identity in a series of abstract formulæ. Since it is for the sake of the individual that the procedure of selection is created, it would be absurd to suppose that in the process the individual disappeared and only the method remained. That individual personality is a stubborn entity and will resist all threats, physical and psychological, to destroy it, is emphasised by Zilboorg (1939). Writing as a psycho-analyst he points out that, since almost every individual is convinced of his immortality and his personal freedom of choice, these convictions must be respected.

If, as a result of a deep inquiry into personality, some prejudices are attacked, some myths exploded, and some convictions questioned it will not be a threat to the individual but a service to him.

Who Shall Select the Selectors?

I have already indicated that the selectors should be representative of the university as a whole, presided over by the dean. The selectors would therefore be precisely those people who are at present responsible for selection, and who have acquired their authority by the very practical method of usage. It will be the responsibility of the president to sift the evidence and make his decisions accordingly. It will be for him to say—and for a follow-up to show—that the evidence on which he has based his decisions is more or less reliable and valid than former evidence based almost wholly upon academic success. The method of selection here advocated is an addition to, and not a replacement of, existing academic methods.

Will Elaborate Selection not Reduce Variety?

In any selection procedure it must be true that the fewer the criteria of acceptance the greater will be the variety among those accepted. Conversely, the more detailed and rigid the criteria the more will those accepted conform to a type. It is claimed that the criterion present in use—academic success—has the advanta simplicity and thus ensures that a wide variety personalities, so necessary for medicine, is acce According to this view modern elaborate methods wo reduce this variety and create stereotypes. This criticism was levelled at W.O.S.B. It was suggested, example, that a man like Lawrence of Arabia would failed at a W.O.S.B. because he could not be fitted any of the known categories. But these criticisms out of a mistaken view of selection. They are in relation to conformity assessments; but, as has shown, the individual style of the candidate is assessed. Lawrence would have immediately displayed himself at a W.O.S.B. as an exceptional person and obvious leader in many of the test situations. Wh a simple examination would merely record that he an outstanding intellect, the W.O.S.B. procedure would be able to add much more about his personality as whole. And this enriched picture would conduce a better kind of choice than would be the case with written examination alone.

At any rate the question remains open, and will doubt be answered with more certainty at the end of the experimental period.

COUNSELLING

The idea of a student advisory service is not new. Most arts faculties have their advisers of studies, and the introduction of the student health service into some universities has afforded the student further opportunities for bringing his problems to a member of the staff for solution. But of the intimate emotional problems which beset every student at some time in his career—in relation to failure, to altered circumstances at home, to his loves and hates—we know almost nothing. Some of the more severely maladjusted are referred to the department of psychological medicine. Other students report of their own accord. It can, however, be inferred from the scanty information available that a problem great magnitude exists, of which we are h aware.

A hint that all is not well is shrewdly given by M (1947) in his review of the student health service in Aberd "conditions which students make for themselves can be depressing, both mentally and physically." He refers to banks of examinations," abandonment of physical late hours of working, bad landladies, poor food, and stringency as having a bad effect on the student's He emphasises the need for "clear sound advice" in rel to exercise, rest, relaxation, vacations, sexual disturban and the like, and of "just letting the student himself."

A high incidence of anxiety among students was found Parnell (1947) in a pilot survey of 155 students of either at Oxford. Mayer-Gross (1948), commenting on the figur given, estimates that emotional disturbances were present half of those examined.

In American universities the same problem is being encountered, and departments of psychology and psychiatry devoting much time to the counselling of students in di culties. Blos (1946), Rogers (1946), Combs (1946), and other have described the technique of "non-directive therapy" dealing with the problem. *This is little more than a* skilful handling of the situation Macklin has described "letting the student unburden himself." In talking free about himself and his problems he is guided towards a solution of his own choosing, and by objectifying his conflicts better able to deal with them, to gain a clearer emoti insight, and to adopt new and more satisfactory attitud life.

In the proposed scheme of research at Aberdeen it expected that much will be learned of the nature variety of students' problems. The results may indic a more urgent need for the establishment of a counsell service than has hitherto bec cted. Thus tang

THE LANCET

LONDON: SATURDAY, AUGUST 28, 1948

Selected Seed

To get a good crop of doctors one needs not only od soil and good cultivation but also good seed. the past few years much has been written on the ltivation of the medical student, and some compre nsive horticultural directions have lately come from e British Medical Association.[1] Relatively little, wever, has been said about the selection of the ed that is to be cultivated, and we have therefore osen this as the main subject of our educational mber for 1948. The information and papers we ve collected show that in fact a good deal of thought at last being given to the fundamental question how to select the right students for medicine. ormerly there was less need, for the students mostly lected themselves: the number of applicants was tle more than the medical schools could hold, and e authorities had no more to do than reject the bviously unsuitable. Now, on the other hand, the pplicants are so many that the selectors have creasingly a positive rather than a negative task; stead of excluding losers they have to pick winners, hich is far harder. Must they still rely on academic ests, school records, and personal impressions, or re there any useful new methods of assessing young eople's capabilities?

Before thinking about methods of discovering ualities, we ought surely to know what kind of ualities we seek. What are the ones that make a ood doctor? High intelligence perhaps? But some aluable doctors have had only just enough intelligence o pass their qualifying examinations. Acuity of bservation? But observation varies with interest, which cannot be judged before training is begun. Specific aptitude for medicine? But psychologists ssure us that aptitude can be confidently identified only in respect of basically different functions such as mathematics and manual dexterity. Sense of vocation? But in the applicant of, say, 17, whose interests and personality are not fully moulded, this is often fleeting. (We are told that at this age about half the applicants intend to become surgeons, while the other half want to be psychiatrists!) The truth is that, since a doctor may pursue any of a score of different careers within medicine, no single answer to our question can be found: for which we should perhaps be thankful, since it would certainly be disastrous if the profession were all of a type. Medicine in fact defies the job-analysis which in other fields is deemed essential to rational selection: and it follows that in the choice of medical students progress can come only from empirical studies. But this empiricism is no excuse for mere adherence to the status quo, particularly as the efficiency of existing methods, apart from impressions, is unknown.

Everyone agrees that certain minimum standards of general education and intelligence should be required; and these have usually been gauged by examinations taken at school. Besides offering a rough guide to intellectual accomplishment the results indicate whether the student is likely to get over the similar hurdles he will meet in his medical career. On the other hand, by themselves examinations can be an unsteady guide. In a debate in the House of Lords last May, Lord **Elton**[2] declared:

> "So far as the traditional examination goes . . . the successful candidate need possess neither common sense nor common honesty, neither courage nor adequate physique, nor even an original mind. It is the kind of examination in which Shakespeare and Cromwell, and almost certainly Mr. Winston Churchill, would have ignominiously failed. For in early years the possession of a strong character or original mind only too often serves as a sort of non-conductor for the ideas of other people . . ."

Recognising the deficiencies of the school examination in measuring ability, some universities are beginning to turn to intelligence tests for supplementary information. With such tests random marking is eliminated and a quick answer is obtained: and though it may not always be the right answer the work of **Eysenck**[3] and others indicates that a higher correlation of assessment with performance is achieved by considering the results of examinations and intelligence tests together than by relying on either singly. Investigations now proceeding, some of which are described in this issue, may bring to light a group of tests more consistently reliable than any at present employed.

A great deal more than intelligence goes to the making of a good doctor; and the student who by average standards is insufficiently intelligent may, if stable and determined, not only succeed in qualifying but become a better doctor than his brighter unstable friend. In the final analysis, therefore, examination results and intelligence tests do not fully prove a candidate's suitability or unsuitability, which can be judged only with knowledge of his character, temperament, and personality. On a later page we review some of the methods now used for such judgment, while in another article Dr. **Millar** tells of a proposal at Aberdeen to obtain a fuller picture of character and capabilities through adaptation of the War Office Selection Board procedure. Though their methods may not prove to be applicable, both W.O.S.B. and the National Institute of Industrial Psychology, which has pioneered selection for industry, can offer useful experience to the medical selector. For example, comparison of the initial W.O.S.B. assessment with subsequent performance during training shows that, while the procedure can be valid, validity varies between the different boards. Though based on scientific principles, it cannot be entirely independent of the people operating it—a fact evident also at medical schools. It benefits from the help of the few who have a flair for their task, but the possession of this flair can be proved only by cold statistics; and there is merit in the W.O.S.B. practice of checking individual selectors' assessment against the candidates' later performance.

At every stage the need is for more facts; and until validation is obtained the advocate of one system is in no position to decry another. The more

[3] Eysenck, H. J. *Brit. J. educ. Psychol.* 1947, 17, 20.

Lower, and comprises a review of ancient and modern knowledge on the subject together with a completely documented account of the author's researches, both by dissection and cineradiography, on hearts from about 200 specimens of all types of mammal. His conclusion is that the shape and size of the eustachian valve are determined by the interaction of the currents of blood during development, but the information given is so complete and interesting for its own sake that the actual conclusion does not seem to matter greatly. We should perhaps explain that about three-quarters of the book is devoted to records which, while individually interesting, will be completely read only by the few. Many, however, will wish to have this scholarly work on their shelves for the sake of the uniqueness of its text and the range of its bibliography.

Surgical Pathology of the Mouth

E. WILFRED FISH, M.D., L.D.S. Manc., D.D.SC. Melb., D.SC. Lond., F.D.S. R.C.S., dental surgeon, St. Mary's Hospital, London. London: Pitman. 1948. Pp. 463. 50*s*.

Mr. Fish's researches are well known, and most of this book is founded on original work. He remarks that "the first chapter is not even very much concerned with pathology, for it seemed necessary to review the biological status of the dental tissues, which are highly specialised and have perhaps received rather scant attention at the hands of physiologists and biochemists." Dental research in the past has indeed received too little attention, and much empiricism has crept in. Whether it would be wise to initiate students with applied dental pathology instead of general pathology is a moot point, but the book should certainly be read by all dental students at some stage in their syllabus, and by all practitioners. The exposition is clear, and is the more lively because the opinions expressed are often personal.

Practice of Industrial Medicine

T. A. LLOYD DAVIES, M.D. Lond., M.R.C.P., chief medical officer, Boots Pure Drug Co., Nottingham; with a chapter on the *Hazards of Coal Mining* by G. F. KEATINGE, M.D. Dubl., D.I.H., medical officer, Butterley Co., Ripley, Derbyshire. London: J. & A. Churchill. 1948. Pp. 244. 15*s*.

THIS book has two outstanding features—its remarkably high content of information and its strong flavour of what is now called social medicine. Dr. Lloyd Davies has managed to infuse into its pages his vigorous and stimulating personality, with his intense concern for the welfare of the factory worker, particularly of the young worker. His understanding of the historical and immediate aspects of social problems is conveyed mainly in the historical survey and in a separate chapter entitled the Social Functions of Industry. These two chapters, at least, should be read by all those interested in social and occupational medicine. He pays tribute to the men of all classes, such as Lord Shaftesbury, Attwood the banker, Fielden the mill owner, Oastler the land agent, Jones the barrister, and many others such as Southwood Smith, Chadwick, Farr, and Engels, who studied the industrial and social conditions of their times and roused the public conscience against the evils created by industry. If anything, he understates the part played by the long line of doctors who acted as an antidote against the social poisons of the Industrial Revolution. Praise is given to the factory inspectorate and due weight to the courage and vision of the four original inspectors—Horner, Howell, Rickards, and Saunders—who "not only laid the foundation of our present system of factory inspection but also exerted a lasting influence on the development of education." (Even in 1833 they were thought to be worth £1000 a year!)

Industrial diseases and toxicology take up about half the book, the descriptions being well documented with up-to-date references and emphasis being laid on prevention and practical treatment. The psychological causes of disease in industry receive attention; the legal aspects are not ignored; and full discussion is given to accidents, fatigue, and environment. Among other things, a works doctor will obtain much information on the proper running of a factory medical service and the salient points about compensation and reablement. The causes of strikes are ably analysed, but one misses a companion piece about lockouts. The book is a valuable one if only for the fact that Dr. Lloyd Davies has not hesitated, as he says in his preface, to add his own opinions to the information gained from the writings and experience of others. And his own opinions are entertaining and provocative.

A Handbook of Ophthalmology (6th ed. London: J. & A. Churchill. 1948. Pp. 336. 21*s*.).—Mr. Humphrey Neame and Mr. Williamson-Noble have not changed the general form of their book but have made some additions and corrections. The use of penicillin in conjunctivitis has been included, while Ballantyne's work on retinal changes in diabetes and the formation of micro-aneurysms indistinguishable from hæmorrhages to the ophthalmoscope is briefly recorded. New work on the effect of drugs on the pupil describes the mode of action of atropine, homatropine, and adrenaline. (The statement that the latter has "little effect as drops" does not hold good if the drops are 1 or 2%.) The volume is handy in size and well produced. It provides students with a precise and accurate account of eye diseases and practitioners with a good description of recent [illegible] and discoveries.

Clinical Diagnosis by Laboratory Methods (11th ed. London and Philadelphia: W. B. Saunders. 1948. Pp. 954. 37*s*. 6*d*.).—The 11th edition of this textbook by Prof. J. Campbell Todd and Prof. A. H. Sanford covers a wide field, and it will remain one of the first works of reference on clinical pathology. The authors still prefer the old-established tests for renal function—such as the phenolsulphonphthalein excretion, Mosenthal's test meal, and the concentration and dilution tests—to the more modern inulin and diodone clearances. The chapter on blood is particularly well illustrated, including coloured diagrams. Rh blood types, cross-matching, blood groups, and heredity are fully described. Over 100 pages are devoted to clinical chemistry, including details of laboratory methods for estimating vitamins, hormones, drugs, and toxic substances in blood, enzymes, and the like. Only brief mention is made of streptomycin. Each chapter contains adequate references, and the book is well indexed.

An Index of Treatment (13th ed. Bristol: J. Wright. 1948. Pp. 984. 84*s*.).—Sir Robert Hutchison and Dr. Reginald Hilton must have had an unusually difficult task, in this edition, to keep pace with the rapid increase in knowledge of therapeutics—a task made more difficult by the problem of what not to include. To cover the whole range of medical, surgical, and gynæcological treatment in less than 1000 pages is an achievement, and to have squeezed in all that is now of practical importance to the busy general practitioner is still more remarkable. Contributors have gallantly pruned their articles, leaving only the clear essentials and precise practical instructions. Little space is given to general and theoretical considerations, except perhaps in articles such as that on medical reablement. One of the most pleasant characteristics of the book is the lucid English in which it is written. It is helpful, too, to have a clear emphasis given to the reader when there is a choice of alternative treatments. Nothing but praise can be given to editors and authors alike for a book of the utmost value and the highest authority.

An Atlas of Anatomy (2nd ed. London: Baillière. 1948. Pp. 496. 55*s*.).—The second edition of Mr. J. C. Boileau Grant's Atlas includes 200 new illustrations. Monochrome provides the background in most, but colour is used judiciously to draw attention to necessary detail. The illustrations are of the cadaver, and the student will have no difficulty in identifying the structures he is dissecting. Perhaps some representation of the viscera in the position they commonly occupy during life might have been useful in correcting the misleading picture derived from their situation in the preserved body. Abnormalities should be clearly labelled as such in the figures, lest the student, not reading the text in detail, be misled; and a semi-diagrammatic representation of the autonomic nervous system as a whole might have been useful—but these are minor points. The book, costly though it is, should add considerably to the student's pleasure in the study of anatomy.

ad "failure to apply such discrimination to home-roduced books is not only inconsistent, but favours rtain sectional interests at the expense of the nation s a whole."

FILMS FOR DOCTORS

Last year three-quarters of the general practitioners n this country saw a 20-minute film reminding them of ome points in the diagnosis of poliomyelitis. Doctors ppreciate the merits of the medical film, and the cientific Film Association has helped by compiling a amphlet on the organisation of programmes[1]; but nfortunately few new medical films are being made here. his year the Ministry of Health has issued a further one n poliomyelitis and another on patent ductus arteriosus: hile the British Council are finishing, for use overseas, lms on artificial pneumothorax and on bronchography. he Central Film Library holds the largest collection of odern medical films in Britain; and yet it contains nly eleven besides the well-known series on anæsthesia ade for Imperial Chemical Industries.

Expense need be no bar to greater production. The ost of last year's poliomyelitis film was equal to 10*d.* er head of those who saw it within a month of its ompletion; and, for an annual allocation of 5*s.* each, eneral practitioners could have five similar films every ear, on such subjects perhaps as the management of heumatoid arthritis in the home, the early diagnosis of cute appendicitis, breast-feeding, and the treatment f septic hands. Experience has already proved that olour and animation, though raising the cost, are often ssential; but whether the duration should preferably e 20 minutes or, more ambitiously, a full hour is not et certain. What is certain is that each film must be esigned for a specific audience, whether of practitioners r of specialists in training; and if a useful series is to e built up over the years there must be a long-term rogramme guided by a central agency such as the inistry of Health or the Postgraduate Medical Federa-ion. (The Scientific Film Association has already ubmitted to the Ministry a five-year programme for lms on health education.)

The immediate need could be met if the Central Film ibrary were enabled to obtain more films from over-eas. At present this library is empowered to acquire or all its sections only twenty films a year, though for he cost of the Ministry of Health's latest film on polio-yelitis it could get multiple copies of a hundred films rom abroad. The excellence of some of these was emonstrated this month at the International Congress n Mental Health. Even twenty-five films from the large tocks in North America would provide much stimulating material. The £1500 needed for this purpose does not seem too much to spend on the instruction of 20,000 practitioners.

THE EPILEPTIC AT COLLEGE

"For the epileptic, hindrances to climbing the educational ladder increase with its height." Discussing this text, Lennox, McBribe, and Potter[2] note that in the U.S.A. epileptics now receiving a college education are only a tenth of the proportionate number in the adult population. A questionary sent to 1676 colleges produced replies from 79%. Asked whether they had any rule about the admission or refusal of epileptics, 55% of those replying said they had no rule; 27% admitted epileptics conditionally and 18% refused them. All military colleges refused them, which means (Dr. Lennox and his colleagues point out) that they would reject such military leaders as Julius Cæsar, Peter the Great, and possibly Napoleon. Roman Catholic seminaries reject them because a canon of the church requires it, perhaps because of the old belief that epilepsy meant demoniac possession. In general the smaller the college the greater the reluctance to accept epileptics: 40% of colleges with more than 2500 students take them, but only 14% of colleges with less than 100. The number of epileptics per 1000 students in the colleges studied was 0·48, which makes a total of 480–500 (allowing for unrecognised cases) in American colleges and universities. Four reasons for this small (by American standards) enrolment are considered: colleges may be rejecting epileptics as a general policy; or epileptics as a class may be below the necessary standard in intelligence, personality, or means; or their attacks may be severe and frequent; or some may have taken a chance and succeeded in concealing their condition from the authorities. The writers of the article hold that the intelligence of epileptics not segregated in institutions is mainly good and often above the average; and they believe there is no distinctive "epileptic personality" among intelligent epileptics. Severe and frequent fits must necessarily debar an epileptic from a college career; but thanks to better drugs and more accurate assessment by means of the electro-encephalograph, epilepsy is becoming a controllable disorder in many cases. The college, they suggest, needs to be assured of three things about an epileptic: that he requires education, that he can and will profit by it, and that he will not be too great a responsibility for the administration. The third is the only one likely to present difficulties.

MENTAL HEALTH: INTERNATIONAL AND DOMESTIC

> *"There is already a world community, at least in embryo. There are already world citizens. . . ."*

The Preparatory Commission[1] appointed to make ready the way for the International Congress of Mental Health, having considered the group studies of mental-health problems sent from 27 countries, see the world as a unit in the sense that events in one country have repercussions in all, that the food-supply in producer countries affects consumer countries, and that nations depend on one another for raw materials and manufactured goods. In their statement they discuss the hesitant steps mankind has taken towards forming a world community: joint action over famine and disease, trade and shipping conventions, a postal union, and scientific and cultural exchanges were all in being before the 1914–18 war; and between the wars which divide peoples other factors were at work to draw them closer together—easier transport, radio, and the deliberate creation of world institutions, some of which are now several generations old. The United Nations' special agencies, such as the Food and Agriculture Organisation, the Educational, Scientific and Cultural Organisation, the World Health Organisation, and the International Labour Organisation are well established. A body of "world servants" are growing up who combine nationality with a wider loyalty; a growing number of scientists and writers have a "world *outlook.*" Whether or not this view is too optimistic, progress towards world citizenship is one of the *most* promising auguries of world peace and should be fostered. The sessions of the congress ended appropriately with the formation of a World Federation for Mental Health, which will have offices at Geneva and will collaborate closely with W.H.O. About 150 of the delegates to the congress from 42 countries were responsible for forming this body, which is however interprofessional rather than international. Dr. J. R. Rees, elected the first president of the federation, explained that membership will be open, not to countries or individuals, but to societies and bodies whose complex the job, the longer validation takes; and universities may perhaps decide that the best hope of speedy progress lies in continuing with their present techniques, at the same time adopting an alternative either as a "shadow" method or for the selection of, perhaps, half their students. One valuable function of the Medical Research Council's committee on selection would be the integration of reports from each centre. In this study special attention will no doubt be given to the student who fails to qualify; plainly, his failure is less commonly a reproach to himself than to the system which allowed him to start training, and it is the concern of every selector to find out how the failure might have been predic Similarly, it may prove possible to follow up applicants who have been rejected, and particularly those who afterwards accepted by another medical school; all they know, the schools may now be rejecting some of their best candidates. With many questions still unanswered, one thing is clear: in the future, as in the past, each university must be free to ch its students according to its lights; but protecti of this right should not prevent them from help themselves, and each other, to find out whether t are really getting the students they want. Is their seed the best on the market?

OUT OF PRINT

UNDERGRADUATES need no reminder of the book shortage; to them this is a recurring obstacle that has somehow to be overcome each time they enter a fresh field of study. The extent of their difficulties is reflected in a report from the Association of Scientific Workers.[1] Last spring the association's Cambridge branch made a survey to find out what proportion of books recommended by university science teachers could be had from booksellers, and to what extent the shortage was affecting the demand for American books. Sometimes any of several books are recommended; so the investigators first grouped recommended books under topics, counting the topic as covered if any one of the recommended books was obtainable. They found that no recommended book (whether British or American) was to be had in almost half—44% to be exact—of the 128 topics about which inquiry was made; and, commenting on the present-day student's tendency to cling to books once he has them, they deny that the second-hand market provides any major relief.

There is nothing new about this impoverishment. Originating in the war, it has been accentuated by a number of post-war influences, which we enumerated last year.[2] Commonly the deficiency is attributed to insufficient supplies of paper; actually, it is due rather to over-all incapacity of the printing and associated trades to deal with the demand, which could be met only by reorganisation, with further trained workers and enhanced supplies, including more glue and binding materials. The U.S.A., less embarrassed by these impediments, is naturally bent on filling the gap; and the measure of her success is the growth in the proportion of American books among those recommended at Cambridge from about 10% in 1939 to about 33% at the present time. As with British books, not all the American ones are to be had, for the import of "learned, scientific, and technical books in English" is restricted to 200% of pre-war value; as the actual number of American books ordered has doubled since 1939 and their price has risen by half, the current demand is about 300% by value of pre-war, and thus about two-thirds of the American books required are obtainable. This is still a higher proportion than that for British works, which in the Cambridge study was only just over half (56%). The report acknowledges that the U.S.A., with her large industrial and scientific activity generally, has a greater number and variety of specially qualified authors; and there is no suitable British alternative for many of her scientific and technological works of reference. There are, however, other reasons for the paucity of new British advanced works. In this country authors are placed at a disadvantage by delays in publication, whereby a new American book may sati the demand while its British counterpart is still with publisher; and additional deterrents are lack of time of financial inducement. At the universities incre teaching pressure leaves little time for writing new b and makes it difficult for those who during the war f behind with their reading to catch up. As to finan inducement, publishers try to divide their inadequate resources equally among authors; and small impressions for all mean small royalties for all. With the aim of minimising these handicaps, the report proposes that the Government and universities should—like some industrial undertakings—make special provision for reading and writing, perhaps in the form of sabbatical years; and with important books Government subsidies, it is suggested, might make up for the smallness of royalties.

Home requirements are not the only reason for fostering new works. By her books Britain has earned abroad a great reputation, which on economic and other grounds must be maintained and expanded. Nowadays, to get an average-size page of a textbook set in type costs about £1; and this high cost is reflected in the eventual price of the book. If more books were distributed overseas, the expense of type-setting would be more widely distributed and thus the price of the book could be reduced. There is also the further point that, for the cost of manufacture, books yield a higher profit abroad than almost any other article. Moreover, overseas book sales promote trade in other directions; a country which buys its medical books from Britain will also tend to look to this country for pharmaceutical supplies. Less tangibly, books take an important part in linking the country of their origin with the place where they are read. On each of these scores we should applaud the association's restraint in refusing to recommend that the allocation of books for foreign markets should be impaired for the sake of better supplies at home. At the same time we should recognise the extent to which the shortage in this country derives from determination to sell overseas. The report quotes figures showing that of all books produced here in 1947, valued at over £30 million, 24·5% was exported.[3] No separate figures for scientific works are given; but the case of a well-known work on bacteriology is cited: 6000 copies of this have lately been printed, and of these 4500 were exported; after a two-year wait a Cambridge bookseller, who had ordered 150, received only 5.

As to a remedy, the report is unequivocal: in the absence of a general increase in book production there should be discrimination in favour of "learned, scientific, and technical books." This claim has often been advanced,[2] and has equally often met with the retort, notably from some branches of the trade, that accession to it would amount to censorship. But, as the report points out, discrimination is already exercised in the preference accorded to imported books of learning;

STUDENT SELECTION: PRACTICE AND PRECEPT

How do medical schools decide which students to accept? What are their principles and what is their practice? r the following information we are indebted to many helpful donors.

DEANS and other members of academic and administra- e staffs spend much of their time in assessing the ims of would-be students. Their task has lately come harder than ever. For the coming academic ar one London school has had about 700 applications : 65 places, another 600 for 100 places, and a third 0 for 20 places. A provincial university has had 20 applications for 100 places.

Some think that the present surge of candidates will on subside: after the first world war the number of gistered entrants rose sharply in 1919 to a peak of 20 (see p. 354): but by 1923 it had fallen to 545. So r. however. there are few signs of a reduction in plications and there are grounds for believing that the essure will not diminish materially within the next w years. The number of entrants to medicine tends vary inversely with the nation's prosperity, for in mes of economic uncertainty parents regard medical aining as a good investment for their children. Further- ore, the financial bar to a university education has en largely removed, and a growing number of candidates e seeking places in the medical schools with promises State or local scholarships.

NEW EMPHASIS

The large increase in numbers has not only increased ut also complicated the work of selection. Just as there little difficulty in identifying, at one end of the scale, he excellent candidate with strong claims to a place, is comparatively easy to detect, at the other end of he scale, a few who are unlikely to succeed in a medical areer; and before the late war the task of selectors was imply to cut off this "tail." But now, the problem is o decide not who shall be excluded but who shall be ccepted. The question "Is there any good reason for ejection?" has given way to "Is there any good eason for acceptance?" and the dividing line has omehow to be drawn through the mass of "average" andidates who would formerly have been admitted ithout qualm. Selection procedures have thus to be udged primarily in the light of their capacity for sorting ut the best in this homogeneous group.

VARIOUS METHODS

Methods vary widely. All universities require candi- lates first to complete application forms or questionaries, ometimes also calling for photographs; and a confiden- ial report is then obtained from the headmaster or employer. The information gathered in these ways is used for one of the following purposes:

1. Final selection. This practice is almost extinct.
2. Primary selection, final selection being by interview.
3. Primary selection, in conjunction with the results of a screening test. Final selection is by interview.
4. The information of interviewers. All candidates are interviewed.

Oxford and Cambridge have their own methods of selection, based on examination and informal interview by the college to which the candidate has applied.

APPLICATION FORM

The application form gives indispensable information about nationality, age, domicile, academic record, and non-academic achievements.

Nationality.—The universities are so fully occupied with training students born in the United Kingdom that andidates from overseas, whether from the Dominions r Colonies or from foreign countries, can seldom be given a place. At more than one university, however, a small quota of overseas students is deliberately accepted for the sake of their broadening influence.

Age.—Regulations often allow admission about the 17th birthday; but most schools prefer students to enter about their 18th birthday. The maturity, application, and resourcefulness of most ex-Service students demobilised at the end of the war have been taken as an argument for imposing a break between school and university. Clearly there are advantages in a break,[1] for it enables the student to stand back and consider where his interest lies, and in this way it eases the selectors' task. On the other hand the men who returned from the war to the study of medicine are a specially selected group, since only those with resource and genuine interest would contemplate further academic training after a break of up to six or seven years. Many are married and acutely aware of the need to qualify and start earning a living. Today, three years after the war, the quality of ex-Service students is tending to fall and that of schoolboy applicants to rise; and since service is now being reduced to twelve months some schools think they should no longer be obliged to reserve up to 80% of places for men from the Forces.

Domicile.—Unless they could live at home, some students would have difficulty in meeting the costs of training, and provincial universities therefore give preference to candidates living in the immediate neighbourhood. This bias in favour of local candidates is often favoured by the fact that the university is supported from local resources. The merit of this system is that the university establishes close understanding with the local schools, which supply most of the students: the principal drawback is that students are denied the opportunity of mixing with others from different parts.

Academic record.—Selectors often find it hard to judge the candidate's recent academic achievements, since the school certificate has been taken some two years before application, while the result of the higher school certificate examination may not be known until a month or so before the academic year begins.

This difficulty will be largely overcome with the introduction, after 1950, of the general certificate, the examination for which will be held after the 16th birthday, and at Easter. In one way, however, this new examination will impose a fresh burden on selectors; for in it all subjects are to be optional. The present requirements, by which a pass is needed in at least one subject in each of several groups, may sometimes operate unfairly against the brilliant but erratic: yet it is a fair guide to general intelligence. The new practice offers promise of success to the boy or girl who excels at, say, mathematics but is useless in other fields; and selectors will thus have to scrutinise and interpret results with even greater care than now.

Some medical schools are guided by the rule-of-thumb that candidates who have not gained matriculation by their 17th birthday are unlikely to succeed in the professional examinations. Though sometimes a moderately good pointer, this rule makes no allowance for the boy or girl who, seeing no need for haste, defers completion of the matriculation examination; nor for the one who has had a long illness, or has been badly taught, or (as sometimes happens with people who later succeed) has been simply idle. At the opposite pole is the tragic group of students—possibly identifiable by intelligence tests—who, having succeeded in early examinations, fail at the university. Commonly it is supposed that, through being overpressed at school, these students reach the university intellectually spent; but perhaps a more likely explanation is that their intellect has fully developed earlier than that of their compeers.

---

1. *Lancet*, 1947, i, 375.

purpose is the promotion of mental health and human relations.

Dr. Rees complained that the federation was at present overweighted with psychiatrists; and indeed this imbalance has affected the congress too. Men and women in many other professions—teachers, clergy, social workers, probation officers, lawyers, and others—must contribute to the study of the mind and its needs and purposes. Teachers of children are especially important, not only because of the facts about mental development which they can contribute but because they stand in such an intimate and important relation to the growing child, and are capable of influencing greatly the standards of every new generation. Miss Isabel Laird, who spoke in the session on planning for mental health, deprecated the fact that the preparatory commission sat without the help or advice of a single teacher of normal children, and that none of the delegates at the congress, so far as she knew, was a practising teacher. Yet it is surely on studies of the normal child that a sound mental-health programme must be founded; for a mentally healthy community is a product of the good upbringing *of normal children. She wished to see better* selection of entrants for primary-school teaching, more opportunities for mature men and women from other occupations to enter teaching, greater chances for teachers who proved unfitted to teaching, or to whom it was uncongenial, to change their calling, and regional staff colleges at which teachers could meet each other and members of other professions to hear and exchange modern ideas about children.

Such practical suggestions, which at first sight may seem to be among the small fry netted at a congress of this kind, are in fact among the big fish in the catch. Mental health and ill health have their beginnings in infancy; and though the cradle need no longer be considered a cumbersome snailshell which we are doomed to carry through life, it is certainly a dangerous refuge in which to lurk too long. Good care from parents later, and good schooling in a liberal tradition, can help us to outgrow some of our earliest mistakes, as other speakers at the congress showed. World health, whether mental or physical, is built on a sound programme of national and ultimately on domestic health.

In summing up the session Dr. George Stevenson, medical director of the American Committee for Mental Hygiene, discussed his ideas on the origins and development of such a programme—ideas set out more fully in a paper published at the congress. His experience of some fifty different States has made him well aware that even within one country there are variations in the background of law and culture which dictate different types of planning. In the very first stage, when ways and means are still to be considered, plans will differ with the authority establishing them. In the United States, governmental responsibility lies theoretically with the citizen; but in some States the citizens see the government as a separate entity from themselves and expect it to be responsible for such things as mental-health schemes. Elsewhere, interested citizens may take the initiative. In either case, citizens who attach importance to mental health will be called together: some—like doctors, clergy, social workers, judges, teachers, and nurses—because of their professional interest, others because an acute personal experience of mental illness in their families has roused their desire to prevent the same misfortune for others. Sooner or later this interested group must survey existing arrangements and plan for their improvement.

It is inevitable and right that their attention should be directed at the outset to the care of the mentally ill and everywhere they will find scope for great advances. "Presumably," Dr. Stevenson said, "the mentally ill person should be given at least as high a standard of living as obtains in the community from which comes." He rarely gets it. In almost every way the mentally ill live in debased conditions. Their housing is bad, largely because of our habit of "storing them in buildings." Dr. Stevenson suggests that much more outpatient care, and many more training centres and centres for occupational therapy could be provided. Mental hospitals should be reserved for their proper purpose of treating the acutely ill; where they are used merely as asylums they become antiquated, over-crowded, often infested with vermin, poorly safeguarded against fire, and an improper background for modern care and treatment. Yet in many parts of the world there are not even asylums; patients are kept in back rooms, or in gaols, or wander the countryside.

By and large the mentally ill are worse fed than other people; because they destroy their clothing they are often poorly clad or allowed to go naked; where staff is scarce they may be unnecessarily restrained; and the standard of cleanliness both of their quarters and their persons may fall below any tolerable level. Moreover, whereas the physically sick man can count on help *consideration during his convalescence, the mentally* patient has no allowances made for him, and dis and stigma retard his readjustment. Nor is treat always adequate: indeed, the insane patient may never get the treatment which could restore him, and often his chance of recovery is lost because well-meaning friends, fearing the stigma of the mental hospital, postpone his admission. The nurse, doctor, clergyman, teacher, lawyer, social worker, police officer, magistrate, public-health authority, and employer are not trained to recognise and manage well the early signs of mental illness or mental defect. Though we are now aware of some of the factors which help to provoke mental illness, we make little effective effort to be rid of them. Specific factors are syphilis and alcoholism; non-specific factors are early experiences, including especially the broken, or potentially broken, home. Positive mental health has to do with the capacity to live a full and satisfying life, and hence with the opportunity the young person gets for growth and development in his society. The group of interested citizens who have surveyed the ground and decided what is to be done must form themselves into a strong and enduring body for the purpose, and work with government bodies that have the same ends in view. Again and again work of this kind in all countries is hampered by lack of trained staff; and the training of staff is a problem for the nations to solve.

If enough responsible people have determined on an effective mental-health scheme, ways will be found to overcome this and other difficulties. The danger is in apathy, which means in effect—though Dr. Stevenson did not say so—lack of funds; and he pointed out that it is no use trying to be economical in a matter of such importance. Funds are probably not such an acute difficulty in the United States as they are here, where bodies such as the National Association for Mental Health are grossly handicapped by poverty. It is unfortunate that large charitable bodies such as the British Red Cross Society have not yet seen the promotion of mental welfare as an appropriate duty; they could put their funds to few better uses and to many worse; and there is good reason to think that public opinion would back them. Dr. Stevenson believes that by continuous and energetic effort it should be possible to enlist one out of every 15 in the population in the cause of mental health. "The will of such a sizable proportion of the population," he suggests, "is a powerful and legitimate force." It is clear enough from all that was said at the congress that if we want a mentally healthy world every country must set its own mental-health service in order. One of the tasks of the new World Federation for Mental Health will be to advise on the development of such services.

Family background.—Importance is attached to stabi- y of family life, since psychiatric disabilities appear develop most often in students from broken or nsettled homes. It is sometimes argued that the udent who comes from a cultured family should be voured because he has had the benefit of an intellec- ually stimulating environment and will have learnt to hink in the way needed in the professions. Particular reference is usually given to the sons and daughters f doctors; as one dean said, "they know the worst."

Previous achievements.—The boy who has been a chool prefect has presumably a well-developed sense of esponsibility and some capacity for leadership. Excel- ence at games does not count greatly at some universities, ut selectors are pleased to discover interest in corporate ctivities and hobbies or recreations beyond the imme- iate school work. The residential universities give articular weight to such interest since they seek students ho give to, as well as gain from, university life.

Intelligence.—Interviewers are usually concerned less ith intelligence itself, which is gauged from the academic ecord, than with intellectual liveliness, originality, and uriosity; and as an example of praiseworthy curiosity he young woman has been quoted who kept mice "to ee whether Mendel's law is right." Occasionally an ttempt is made to gauge actual intelligence.

At Liverpool candidates are submitted just before the nterview to a modified progressive matrices test. The results, hich are not examined until the interview committee has warded its own mark, usually tally closely with the com- mittee's grading: where the difference is gross, the committee's marking may be slightly modified.

It is sometimes said that many of the most intelligent potential students are diverted at school to other callings. Some schoolmasters are believed to exercise a selective preference against medicine, deterring their pupils from the study of science and encouraging the best of those who do study it to engage in pure science, on the assumption that second-rate brains are good enough for medicine. Correction of this habit, if it exists, seems to lie with the universities themselves through closer iaison with schools.

Other mental qualities.—The medical course is a fairly stern test of perseverance, and an attempt must be made o judge whether the candidate has the courage to urvive it. It is also a test of emotional stability; so the claims of the candidate with a history of psychiatric isability have to be examined with special care. At more than one school applicants are asked why they want to enter medicine, and what qualities they consider desirable in a doctor. It is believed that sometimes a genuine sense of vocation can be detected. There has to be equal watchfulness for those who apply because they have no special inclination for any other calling or because they have been pressed to do so by parents or school teachers. The sons and daughters of doctors, despite selectors' preference for them, may often belong to this group.

Personality.—"At interviews" said one authority, "we feel we are examining not so much the candidate as his school"; and there is no doubt that the school and family background may prejudice unfairly the impression given by the adolescent candidate. On the other hand, an immature youth, under strong influence from parents, may assume a veneer which, though thin, s not penetrated in the short time of interview. To detect immaturity is probably more important than to reveal the "likeability" so commonly sought; for many ailures in the professional course derive from inability o bridge the gap between the spoon-feeding of home and school and the more independent personal and ducational life of the university. At the age of selection women appear, in general, to be mentally more mature and therefore more acceptable; but the impression is that men draw level during undergraduate training. Women also tend to have a better general education and wider interests, possibly owing to a more catholic training and less intense preoccupation with examinations and games.

GRADING THE CANDIDATE

When the interview is finished the candidate is allotted a mark (perhaps on a 5-point or 7-point scale) which takes account of all the available evidence. Where the interview has been conducted by a committee, there is free discussion before the mark is decided.

At one medical school candidates used to be seen by each member of the committee separately. Having awarded an individual mark, the members met, discussed their findings, and decided on an agreed mark. This practice has been abandoned because candidates reported that they were being asked the same sort of question by each member; and now the committee sits together. Most members consider the new arrangement equally satisfactory, and it saves them much time. Candidates, too, seem to be equally satisfied with it, though their interview with the committee lasts only as long as the former interviews with each member.

The relative importance attached to academic achievements and personal qualities is usually decided arbitrarily for each case. But at one university an attempt is made to place the marking on a more consistent basis, up to 60% of the total marks being allotted for academic achievements, and up to 40% for personal qualities.

WHAT SORT OF DOCTOR?

In choosing students, university authorities have to picture the general qualities which they hope to find in their graduates. Some hold that a faulty bias has been allowed to develop. One dean, himself a research-worker, said:

> "We have concentrated too much on producing scientists. Our first object should be to get good general practitioners, and our second to get first-class people for scientific research."

Similar views are held at other schools. A second dean said:

> "Our task is to make general practitioners. I know a large number of good specialists, but I can count on the fingers of one hand the really good general practitioners; it is too difficult. The qualities to be sought in the general practitioner are intellectual honesty, a high moral standard, and willingness to sacrifice personal interest for that of others. By concentration on other qualities, especially intelligence, the present tendency is not to pick the student with a strong sense of duty. Yet in the new National Health Service, with the practitioner's financial incentives largely removed, this quality is more than ever necessary."

MULTIPLE APPLICATIONS

The total number of applications to the universities does not by any means indicate the total number of candidates. Uncertain of acceptance by any university, many apply to more than one; and it may be assumed that the greater the number of candidates, the greater will be the number of multiple applications. At present the exact extent of this practice is unknown; but at a university in the north of England where all candidates have lately been questioned on this point, they admitted to applying, on average, to about three other medical schools. Allowing for natural reluctance to admit other applications, and for applications subsequently made, the number of previous applications may, in the case of this university be even greater than three.

The effect is to impose on university authorities extra and unprofitable work since they have to consider candidates who may later announce that they have accepted the offer of a place at another medical school.

At the University of Birmingham an attempt has been made to resolve this difficulty. Candidates are encouraged to apply 18 months ahead of the proposed date of entry. Local schools have been notified of this, but a certain number of places is reserved for late applicants. The bulk of pro-

HEADMASTER'S REPORT

The headmaster's report ought to contain most of the information, gathered over years, which selectors try to elicit in a short interview. Yet it is often of little value either because it does not supply the information required or because it paints too glowing a picture. Asked simply for a testimonial, the master can hardly be blamed for shortcomings in his report; and many universities now call for answers to a series of specific questions. The universities drawing most of their students from the immediate locality have an advantage, of course, in that they learn by experience what weight to place on statements from the various local schools.

TIME OF APPLICATION

At some centres applications are considered at a single fixed date in the year, usually about Easter; at some they are considered at one of two or more fixed dates; and at some they are considered as they are received. Exceptionally, the application list is kept open until the late summer. There is natural reluctance to lose the very promising student, for whose rapid acceptance special provision is commonly made.

The difficulty of interviewing large numbers is beginning to attract medical schools to an arrangement which favours the early applicant, and this year some of them have been accepting applications for 1949 and 1950. At one school where all candidates have hitherto been interviewed, vacancies are in future to be filled with suitable candidates as the applications are received.

Final lists of entrants cannot be drawn up until about a month before the start of the academic year since the results of 1st M.B. examination, which determine acceptance for the second year, are not known until June or July, and it may be necessary to wait until the results of the higher certificate are announced.

A SCREENING TEST

At University College, London, a special examination was introduced in 1943 for the purpose of primary selection. At first this examination was taken only by women candidates, but now it is taken by both men and women. By means of it the number of candidates to be finally selected at interview is reduced to about twice the number of places.

Intending students are advised to apply about a year before they wish to enter; no waiting-list is kept. With their application forms they send a small photograph, which is later used for record purposes. They are next required to complete the entry form for the examination, a non-returnable fee of one guinea being charged to deter those who might otherwise sit the examination for practice. The examination, which has been described by Smyth,[2] consists in multiple-choice questions and an essay, and is directed to gauging intelligence rather than learning. The results of each part of the test are being correlated with the student's later performance; and the practice will be modified accordingly. Students from overseas are usually excused the examination, which last year was sat by 738 out of 900 applicants. This year it will be held in November and will be followed by interviews in February and March. Those wishing to enter in either 1949 or 1950 can apply.

At another medical school a similar screening test has been discarded because it was not thought to justify the time taken in setting and correcting the papers and generally organising the examination.

THE INTERVIEW

At some schools candidates for interview are seen only by the dean or his representative, whereas at others they are seen by a committee of 3–7, designed to represent the various teaching interests, which usually includes a woman where women candidates are to be considered. Each practice has its firm defenders. Some say that the committee method reduces the chance of the candidate becoming the victim or beneficiary of individual prejudice; others prefer selection by a single person, on the following grounds:

1. All candidates are scrutinised under the same conditions. Membership of a committee often varies through unavoidable absences or because the members are selected in turn from a panel. Though the dean or senior administrative officer is always present, it is sometimes noticed that his influence does not suffice to prevent variations in criteria.
2. Rapport with the candidate is more readily established by a single interviewer than by a group.
3. Compared with a group drawn from busy heads of departments a single selector is more likely to devote enough time to the work.
4. The single selector often develops a genuine faculty for selecting suitable students.
5. In a committee the member with the strongest personality or convictions is apt to impose his views on the rest of the committee. (This is supported by accounts of disagreement being rare—for instance, "in less than 5% of cases"—which does not suggest much exercise of individual judgment.)

Nevertheless, the committee method has such potential advantages that these contentions should perhaps be used for strengthening rather than abandoning it. For example, members could each allot an individual mark before the final mark was discussed; and constancy of membership might be assured through sterner preliminary elimination, which would reduce the demands on the committee's time.

The *length of the interview* varies at different schools from 5 to 20–30 minutes; and 10 minutes seems to be the most usual time. The proportion of candidates interviewed varies from about twice the number eventually selected up to the total number of applicants; and in general the larger the proportion of candidates interviewed, the shorter is the time given to each.

CONTENT OF THE INTERVIEW

The aim is always to establish an easy, friendly atmosphere; and commonly an approach is made by checking facts on the application form before proceeding to a discussion of interests and finally to a search for any special traits that the interviewers wish to uncover. At Liverpool candidates are asked, before the interview, to indicate on a *pro-forma* their interests and their dislikes. This has been found to save time and to help in establishing rapport.

At no two universities is the task of interviewing approached with quite the same aims; but in general the purpose is to determine the candidate's background, intelligence, interests, character, and personality.

Educational background.—Preference is given to the applicant with a good general education and with some knowledge of the humanities. More than one school complains of poor general education in many of their candidates, attributing this largely to early specialisation and particularly to preoccupation with the higher certificate examination, which has to be passed by those seeking county scholarships. Similarly, a pass in the first M.B. examination before entry is often not regarded as a high recommendation.

At Liverpool a letter sent to local headmasters emphasises the importance of a good general education and points out that absence of qualifications in chemistry, physics, and biology in no way disqualifies applicants from admission.

The large number who pass the 1st M.B. examination before admission is an embarrassment to some universities, which find that they have relatively more places for those starting on the 1st M.B. subjects than those beginning on the second.

This has led one medical school to take for the 1st M.B. course and examination students who have already passed the examination; and students are reported to enjoy this second course, since the approach is different from that at schools. Other medical schools, however, consider this plan unprofitable to the student and discouraging to the teacher.

At Liverpool candidates are submitted just before the terview to a modified progressive matrices test. The results, hich are not examined until the interview committee has rarded its own mark, usually tally closely with the com-ittee's grading: where the difference is gross, the committee's arking may be slightly modified.

It is sometimes said that many of the most intelligent otential students are diverted at school to other callings. ome schoolmasters are believed to exercise a selective reference against medicine, deterring their pupils from he study of science and encouraging the best of those rho do study it to engage in pure science, on the ssumption that second-rate brains are good enough for nedicine. Correction of this habit, if it exists, seems o lie with the universities themselves through closer laison with schools.

Other mental qualities.—The medical course is a fairly tern test of perseverance, and an attempt must be made o judge whether the candidate has the courage to urvive it. It is also a test of emotional stability; so he claims of the candidate with a history of psychiatric lisability have to be examined with special care. At nore than one school applicants are asked why they rant to enter medicine, and what qualities they consider lesirable in a doctor. It is believed that sometimes a genuine sense of vocation can be detected. There has to be equal watchfulness for those who apply because they have no special inclination for any other calling or because they have been pressed to do so by parents or school teachers. The sons and daughters of doctors, despite selectors' preference for them, may often belong to this group.

Personality.—"At interviews" said one authority, "we feel we are examining not so much the candidate as his school"; and there is no doubt that the school and family background may prejudice unfairly the impression given by the adolescent candidate. On the other hand, an immature youth, under strong influence from parents, may assume a veneer which, though thin, s not penetrated in the short time of interview. To letect immaturity is probably more important than to reveal the "likeability" so commonly sought; for many ailures in the professional course derive from inability o bridge the gap between the spoon-feeding of home and school and the more independent personal and ducational life of the university. At the age of selection women appear, in general, to be mentally more mature and therefore more acceptable; but the impression is that men draw level during undergraduate training. Women also tend to have a better general education and wider interests, possibly owing to a more catholic training and less intense preoccupation with examinations and games.

GRADING THE CANDIDATE

When the interview is finished the candidate is allotted a mark (perhaps on a 5-point or 7-point scale) which takes account of all the available evidence. Where the interview has been conducted by a committee, there is free discussion before the mark is decided.

At one medical school candidates used to be seen by each member of the committee separately. Having awarded an individual mark, the members met, discussed their findings, and decided on an agreed mark. This practice has been abandoned because candidates reported that they were being asked the same sort of question by each member; and now the committee sits together. Most members consider the new arrangement equally satisfactory, and it saves them much time. Candidates, too, seem to be equally satisfied with it, though their interview with the committee lasts only as long as the former interviews with each member.

The relative importance attached to academic achievements and personal qualities is usually decided arbitrarily for each case. But at one university an attempt is made to place the marking on a more consistent basis, up to 60% of the total marks being allotted for academic achievements, and up to 40% for personal qualities.

WHAT SORT OF DOCTOR?

In choosing students, university authorities have to picture the general qualities which they hope to find in their graduates. Some hold that a faulty bias has been allowed to develop. One dean, himself a research-worker, said:

> "We have concentrated too much on producing scientists. Our first object should be to get good general practitioners, and our second to get first-class people for scientific research."

Similar views are held at other schools. A second dean said:

> "Our task is to make general practitioners I know a large number of good specialists, but I can count on the fingers of one hand the really good general practitioners: it is too difficult. The qualities to be sought in the general practitioner are intellectual honesty, a high moral standard, and willingness to sacrifice personal interest for that of others. By concentration on other qualities, especially intelligence, the present tendency is not to pick the student with a strong sense of duty. Yet in the new National Health Service, with the practitioner's financial incentives largely removed, this quality is more than ever necessary."

MULTIPLE APPLICATIONS

The total number of applications to the universities does not by any means indicate the total number of candidates. Uncertain of acceptance by any university, many apply to more than one; and it may be assumed that the greater the number of candidates, the greater will be the number of multiple applications. At present the exact extent of this practice is unknown; but at a university in the north of England where all candidates have lately been questioned on this point, they admitted to applying, on average, to about three other medical schools. Allowing for natural reluctance to admit other applications, and for applications subsequently made, the number of previous applications may, in the case of this university be even greater than three.

The effect is to impose on university authorities extra and unprofitable work since they have to consider candidates who may later announce that they have accepted the offer of a place at another medical school.

At the University of Birmingham an attempt has been made to resolve this difficulty. Candidates are encouraged to apply 18 months ahead of the proposed date of entry. Local schools have been notified of this, but a certain number of places is reserved for late applicants. The bulk of provisional acceptances is made in September of the year before entry, by which time the number of places for 2nd M.B. students in the subsequent year can be estimated. Those offered provisional acceptance are given up to 4 weeks in which to withdraw applications to other universities; and they must sign a declaration that they will accept the offer. Commonly the result of the higher school certificate or 1st M.B. examination, on which final acceptance depends, is not known; but from academic records and headmasters' assessments the number who will succeed can be gauged within narrow limits.

Without concerted action there can be no general relief from the effects of multiple applications. One medical school has suggested that all candidates for the London schools should be required to place their names on a central register, at the same time naming schools in order of preference. Applicants would first be considered by the school given as first choice, then, if rejected, by the school of second choice, and so on. Such an arrangement, extended to include all British universities, would reduce the number of candidates to be considered, thus simplifying selection and giving time for more detailed attention to each. It is unlikely, however, that the universities would agree to this course. Rightly insisting on freedom in selection, they often fear that such a device, though voluntary at first, might soon become mandatory; and that central registration would lead to central allocation.

DIFFICULTIES IN SELECTION

About the merits of the various selection methods there are many opinions but few facts; universities may still be choosing some of the worst and discarding some of the best of those that apply. This uncertainty derives from the failure of each method to meet these requirements:

1. It should test suitability for the particular employment which the candidate is to engage in.
2. It should be objective.
3. Its validity should be open to proof by a check of performance against assessment.

Specific tests.—Selectors do not know which path the student will take after qualifying. At entry he may, it is true, express a clear intention; but little or no significance can be attached to this, since it is formed in adolescence, before acquaintanceship with any subject of medicine, and often from romantic notions. Selectors, for their part, are unable to prophesy the career for which the student will be best suited. He may become barrister or bacteriologist, geriatrist or journalist, psychiatrist or surgeon. In medicine there is room for almost every skill; so it may be doubted whether aptitude tests based on analyses of the diverse postgraduate occupations will ever earn a place in selection. There would, on the other hand, be great advantage in prediction of a sufficient aptitude for the subjects in the medical curriculum, for after the 1st M.B. these are different in character from any previously studied. A boy who has excelled in pure science may make a poor showing at medical subjects; and it seems that while the intercorrelation between medical subjects taken at the same time is fairly high, that between 1st M.B. subjects and those of subsequent years is much lower: "a test in medical subjects or subjects of a similar nature might prove of better prognostic value than the present examination in subjects representing merely a general education."[3] With this objective in mind, Prof. L. S. Penrose[4] makes the following interesting suggestion:

> Candidates might be exposed to a miniature medical course lasting 2–3 days and dealing with the chemical, biological, histological, and clinical aspects of a single topic—e.g., inflammation or fractures. At the end they would undergo an examination, which should reveal whether their minds had a real aptitude for medicine. It would prove their capacity for accurate observation, deduction, and judgment on the information provided.

Objectivity.—Usually the only objective evidence in the hands of selectors is the record of examination results and of non-academic achievements; and even those have to be interpreted in the light of the candidate's circumstances and opportunities.

Validity.—Selection and training are directed to the same end—the making of able doctors. Though success in professional examinations may afford suggestive evidence, it does not in itself prove that this end has been gained. Professional examinations are principally tests of factual knowledge, whereas the true criterion is ability to apply this knowledge. These two do not necessarily go hand in hand; and in at least one university the award at graduation to the best student of the year is regarded as a passport to obscurity. In medicine, perhaps above all other branches of science or the arts, there is need for a preliminary test of the candidate's probable capacity for using the knowledge he is to gain at the university. But no such test exists; and since there is no common measure for judging success or failure in the various postgraduate fields, the final examination, despite its shortcomings, must probably be accepted at present as the end-point of any follow-up.

THE FUTURE

Dissatisfaction with existing procedures centres on the inadequacy of the short interview in dealing with large numbers of candidates. At the best an interview, as Oldfield[5] has made clear, is a complex and hazardous undertaking; and universities have to decide whether they are being more just to themselves and to candidates in giving a brief interview to all eligible candidates than they would be in first eliminating some and then considering in detail the claims of the remainder; an interview of 10 minutes, even when backed by other information, is after all a very short time in which to decide a youth's future. At the same time selectors are naturally reluctant to buy increased efficiency in selection at the price of further time lost to departmental duties.

Few doubt that more ruthless preliminary selection is desirable; but how is this to be effected? A properly conducted certificate examination would meet the need. Otherwise, the only possible means, as Smyth[2] has observed, appears to be for the medical schools to set their own preliminary examination. Were this examination to take the form of a test of intelligence, it would provide the least possible advantage to those who had been trained for it at school, though at the International Congress of Psychology in Edinburgh this year Miss A. W. Heim, PH.D., showed that training may improve performance considerably more than has been thought. Such a test may, incidentally, help to reveal those insufficiently gifted to pass the professional examinations. But here the gap between precept and practice is wide. Most authorities are suspicious of psychological tests, and there is still no statistical evidence to allay this suspicion. It can, moreover, be argued that selection by intelligence would eliminate some who, though not specially clever, would nevertheless make good doctors. Some universities are now taking a middle course by using intelligence or other psychological tests to supplement the usual procedures, or simply in order to evaluate their worth.

In whatever direction selection methods evolve, they must always have two aims: first to eliminate before the start of training the student who, for one reason or another, will fail; and secondly to discover the particular type of man and woman which the university wishes to train.

Students Guide

948 1949

Medical Schools

At OXFORD UNIVERSITY the number of new students restricted by decree; and the number for the coming ear has been fixed, as it was last year, at 55 men and 0 women. Ex-Service men and women are only dmitted over and above these numbers if they were orn before Jan. 1, 1929. The various colleges put orward the names of the students they wish to be dmitted to the medical school, and preliminary accepance by a college is essential for any prospective medical tudent. All students entering the school in the future ill be required to take the second public examination s before the war; the course normally taken to satisfy his regulation is the final honour school of animal hysiology, which takes up one year after passing the natomy and physiology examination for the B.M. degree. he newly established clinical school in Oxford enables tudents to qualify at the Radcliffe Infirmary as an lternative to transferring to a teaching hospital in ondon or elsewhere. A students' club has been opened his year in Osler House, in the Infirmary grounds, hich gives social and reading facilities, and sleeping ccommodation for those on duty in the hospital. This ocial, administrative, and teaching centre will be comleted by a lecture-room and a class-room which are oon to be constructed in an adjoining building.

In the UNIVERSITY OF CAMBRIDGE the post of professor f animal pathology has been revived, and it is proposed o establish a school of veterinary medicine. During he preclinical period veterinary students will work in onjunction with their medical brethren in the basic ubjects which are common to both professions. If this proposal of a complete school is accepted, the new venture should be of mutual benefit to both medicine ind veterinary medicine. The natural science tripos, the great and abiding advantage which Cambridge offers, will include instruction by the professor of animal pathology, thus broadening the outlook of the medical tudent. Likewise, veterinary students will benefit from nstruction in the fundamental aspects of human pathoogy. The first step has been taken towards establishing university department of pædiatrics, by the appointnent of a pædiatrician to the staff of Addenbrooke's Hospital. A department of human ecology has been stablished with the appointment of a reader who is argely concerned with epidemiological studies, whilst he university health service, which will carry out prophyactic examinations, including mass radiography, will e ready to work to full capacity on the new intake n October. The department has also appointed a statistician, whose services will be available to all the medical and biological departments. The postgraduate school is now well under way. One of its most successful ventures has been the establishment of trainee posts in the clinical pathological departments of Addenbrooke's Hospital, under the control of the professors of pathology and biochemistry. These posts (which carry a living wage) offer a two-years course of training in all the aspects of clinical pathology, post-mortem work, histology, and chemical pathology. To attract into medicine boys who have not begun to specialise at school, Peterhouse offers a scholarship for medical students in non-medical subjects.

London Schools

LONDON UNIVERSITY bears a different relation to its medical faculty from other universities: whereas they have one school of medicine each, London has the twelve autonomous schools of the teaching hospitals, as well as University, King's, and Queen Mary Colleges, all of which take medical students for some part of the preclinical course. All the medical schools are now open to men and women students.

The preclinical course at UNIVERSITY COLLEGE has now the full use of the facilities interrupted by the war. The X-ray department has been re-equipped, and the museum, which was dispersed during the war, is being replaced as a new type of teaching museum in which the specimens are accompanied by descriptive literature and the functions of the organs are considered along with the structure. Part of the museum has been used to make cubicles for the study of surface anatomy and for human physiological and pharmacological experiments.

KING'S COLLEGE has in its medical faculty one of the largest schools for preclinical studies in London. Its members share fully in the social and athletic activities of students from all six faculties of the college. Clinical studies are pursued at King's College Hospital, St. George's, or Westminster. Arrangements are made by which patients attend the college for clinical demonstrations in applied physiology given by clinicians. Hostel accommodation for a limited number of men is available at King's College Hall, Champion Hill, S.E.5.

The arrangements made by the joint committee of QUEEN MARY COLLEGE and the London Hospital medical college are working efficiently; and now that Queen Mary College holds its own special internal first examination for medical degrees the teaching subcommittee has organised the instruction in physics, chemistry, and biology to fit in closely with preclinical teaching. All available places are taken by London Hospital men and women: during the 1947–48 session 72 first medical and 6 premedical (conjoint) students passed through the departments.

The new health service does not necessitate any immediate drastic changes in the training of students at UNIVERSITY COLLEGE HOSPITAL. The success of the new organisation, in so far as medical education is concerned, will depend largely on friendly coöperation between the members of the hospital boards of governors and the teachers in the medical schools. Members of the boards have not all been chosen because of their interest in medical education, yet it is vital that all should realise that the treatment of sick people can be integrated with the clinical training of doctors-to-be in such a way that the needs of all are satisfactorily met. St. Pancras Hospital and the Hospital for Tropical Diseases have now been taken over; and the total number of beds available for teaching at U.C.H. will soon be well over 1000. St. Pancras has a mental observation unit dealing each year with some 2000 cases of acute mental disorder; it also has an obstetric block which will eventually add some 80 beds to the existing 85 in the parent hospital. Here a unit for the care of the chronic sick is being established.

ST. BARTHOLOMEW'S HOSPITAL medical college is still faced with the problem of fitting an abnormally high number of suitable applicants for entry, many of them ex-Service, into buildings, both of the college and of the hospital, whose usefulness has been diminished by war damage. The second part of the problem is approaching solution. In addition to the temporary repairs which have been carried out during the last two years, a start can now be made on the permanent rebuilding of the preclinical college. On the clinical side increasing use is being made of nearby hospitals to relieve the pressure on the material in St. Bartholomew's itself; and this will continue until the blocks rendered useless by the war can be reopened.

Last October the departments of anatomy and physiology at CHARING CROSS HOSPITAL were reopened in new extensions to the school buildings, and 45 students (20% of them women) have now completed in these departments the first year of the 2nd M.B. course. The venture has proved very successful; and the reunion of preclinical and clinical subjects has benefited both staff and students. The establishment of the National Health Service has had some repercussions on the school, which has now become a legal entity and will be controlled

The revised curriculum introduced last year at WESTMINSTER MEDICAL SCHOOL has proved its worth, and urther changes are being considered. The number of ndergraduate students is rapidly increasing and will each 165 by next April. Under the National Health ervice Act a new board of governors has been formed for Westminster Hospital and its designated hospitals (the Westminster Children's Hospital, the Gordon Hospital, nd All Saints' Urological Centre), and a new council for he school, which will in future be known as Westminster Medical School. The school thus becomes autonomous, ut its links with its parent hospital will be strengthened ather than weakened under the new system, and it will learly play an increasingly important part in medical ducation in its region. That the school is an integral art of London University is emphasised by the appointment to its council of two representatives of the Senate, part from internal members. Women clinical students ntered the school last April for the first time in many ears; separate common-room accommodation has been provided. Competition for entry among women candidates is exceptionally keen; it is hoped to increase the numbers admitted as clinical facilities become available. Plans for expansion have been proposed since existing resources for teaching pathology will soon be severely taxed. There are already enough beds for the clinical instruction of the present numbers. It is hoped eventually to create a 1000-bed teaching centre in the area bounded by St. John's Gardens and Vincent Square, which are a five-minute walk apart. A preclinical school for 150 students is contemplated. Valuable experience of emergency cases is expected from closer integration with St. Stephen's Hospital, Fulham. Closer linkage with child welfare centres in the district will ensure that students obtain instruction not only in children's diseases but in child health as a whole.

At the SCHOOL OF DENTAL SURGERY of the ROYAL DENTAL HOSPITAL of London the curriculum for the first two years includes the study of dental mechanics, dental prosthetics, the properties of dental materials, general anatomy and physiology, and special anatomy and physiology. The anatomy and physiology courses are held at King's College in the Strand. For the second two years students attend lectures and clinics on general medicine and surgery at Charing Cross Hospital medical school, and lectures and practice in dental surgery at the dental school.

Other English Schools

At the UNIVERSITY OF DURHAM there has been a slight decline in the number of ex-Service candidates. This has not affected the total number of applicants, which remains greatly in excess of vacancies. The 2nd M.B. examination has been re-arranged. From next March this will be held in two parts, as before; but part 1, held in March after five terms' work, will consist of physiology only, while part 2, held in June after six terms' work in anatomy, will consist of anatomy and pharmacology and pharmacy. The new department of psychological medicine is now coöperating with the department of medicine in the teaching of undergraduates; and it is hoped that some postgraduate training in psychological medicine will soon be possible.

At the UNIVERSITY OF BIRMINGHAM * a committee has recently been appointed to review the medical curriculum. The course in applied anatomy is in future to be under the direction of the department of anatomy in collaboration with the heads of clinical departments; as soon as the necessary arrangements can be made an integrated course of lectures will be instituted in which the anatomical, physiological, pathological, bacteriological, medical, surgical, and gynæcological aspects of disease will be closely linked. Some modifications in the introductory course are anticipated next year, and students will be directed to medical clerking and surgical dressing as soon as they have completed this part of the clinical curriculum. The regulations for higher degrees—M.D. and CH.M.—have been amended, and the main emphasis will in future be on a thesis based either on original research or on the application of scientific method to medicine or surgery. The regulations for the degree of PH.D. of the faculty of medicine have also been amended. The degree of M.D. in State medicine has been abolished. The full-time clinical professors have been bringing their staff up to full strength. Research programmes are being sponsored in all these departments, to which some promising research-workers are being attracted. The faculty has adopted the principle, observed by older universities, of creating a professorial chair for those whom the university wish to honour. Appointments have been made to the chair of therapeutics and the chair of gastro-enterology—the only one of its kind in the British Isles. A second chair of anatomy has been created. A further innovation is the establishment of two chairs of pathology—one of experimental pathology and the other of morbid anatomy. In the department of medical statistics a new post has been created—that of senior statistical officer. Consideration has been given to the production of films for university education; and a Senate committee has lately been set up to observe developments in this field.

At the UNIVERSITY OF LIVERPOOL * applications are still greatly in excess of the 100 available places. New developments in undergraduate teaching include allocation of specific periods during clerking and dressing for instruction in the administration of anæsthetics and in clinical pathology. Postgraduate teaching offers full-time courses for the degrees of CH.M., M.CH. ORTH., and M.RAD., granted by the university, and for the diplomas of D.P.H. and D.T.M. & H. (the latter in conjunction with the Liverpool School of Tropical Medicine). These courses are also suitable for candidates studying for the F.R.C.S. or D.M.R. examinations. There is a new full-time course in anæsthesia and a course throughout the academic year for postgraduate students proceeding to the degree of M.D., which is usually attended also by candidates for the M.R.C.P. A part-time course in obstetrics and gynæcology is held throughout the academic year, and a short intensive course in pædiatrics, lasting 3 weeks and suitable for candidates studying for the D.C.H., is held once or twice a year.

MANCHESTER UNIVERSITY * admits about a hundred medical students each year. A few of these enter the second year of study because they have passed part or the whole of the 1st M.B. examination externally. A period of six months' residence is obligatory for all medical students during the period of clinical study. This is provided for in a special hostel adjacent to the teaching hospitals. There are facilities for postgraduate work in many special subjects, both ancillary to medicine and in the clinical field. A full-time chair of social and preventive medicine has lately been established, and this department will probably be concerned among other things with the provision of a health service for all university students. A research centre for the study of chronic rheumatism, set up through the generosity of the Nuffield Foundation, is now actively at work. A development which is foreshadowed is the institution of a department of psychiatry, with a full-time professor as its director.

At the UNIVERSITY OF LEEDS * the intake cannot be increased beyond 75 each year without further building. The undergraduate course once more extends to five years and two terms. The 1st M.B. course is closely integrated with the rest of the curriculum; the teaching in zoology is designed as an introduction to anatomy and physiology, and the standard of organic and physical chemistry in this course is in most other schools reached only at a later stage. Under Ministry of Labour regulations, the Leeds 1st M.B. course is recognised as "medical course proper"; and the university does not generally grant exemption from it. During the course attendance at a class of medical mathematics is required of all who have not reached principal standard in mathematics in the higher school certificate examination. During the first year of the 2nd M.B. course undergraduates are encouraged

---

* The entrance requirements for the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham are laid down in the pamphlet *Qualifications for Entry upon a Degree Course*, copies of which may be obtained from the Secretary to the Board, 315, Oxford Road, Manchester, 13. Additional faculty requirements may, however, be imposed: details can be obtained from the dean of the faculty of medicine in each university.

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom, except Reading, offer baccalaureate degrees in medicine and surgery, conferred on the results of examination.

HIGHER QUALIFICATIONS

Those who have graduated in medicine and surgery are at liberty to seek higher qualifications if they wish.

Doctor of Medicine and Master of Surgery

Graduates holding a bachelor's degrees can take the degree of Doctor of Medicine or Master of Surgery. All universities with medical faculties in Great Britain and Ireland confer such degrees. London University offers the M.D. in general medicine, and in pathology, psychological medicine, midwifery and diseases of women, hygiene, and tropical medicine; the M.S. is obtainable in general surgery, and in dental surgery, ophthalmology, and laryngology, otology, and rhinology. At the University of Durham the degree of Doctor of Surgery (D.CH.) is offered in addition to the degree of Master of Surgery (M.S.). Liverpool offers the orthopædic degree of M.CH. ORTH., the regulations for which have lately been revised.

Master in the Science of Obstetrics and Master of Midwifery

The Irish universities grant the degree M.A.O. The Society of Apothecaries of London grants the Mastery of Midwifery (M.M.S.A.) upon examination in obstetrics, pædiatrics, and public health. The examinations are held in May and November, and regulations may be obtained from the registrar, Apothecaries' Hall, Black Friars Lane, E.C.4.

MEMBERSHIP AND FELLOWSHIP

The Royal College of Physicians of London confers the Membership (M.R.C.P.), which is obtained by examination. Examinations are held four times in each year, and medical graduates and licentiates of the college over twenty-three years of age may sit for it. Details can be obtained from the secretary, Royal College of Physicians, Pall Mall East, London, S.W.1. Fellows of the college are elected annually at a general meeting of the college.

The Royal College of Surgeons of England grants a fellowship to those passing the primary and final F.R.C.S. examinations. The primary examination is open to those who hold a qualification registrable in the British Medical Register and to graduates in medicine and surgery of universities and medical colleges recognised by the council. Subjects of the primary examination are anatomy (including normal histology), applied physiology, and the principles of pathology. The final examination can be taken in general surgery, ophthalmology, or otolaryngology. To be admitted to the final examination in general surgery candidates must produce evidence of having been engaged in acquiring professional knowledge for not less than two years (increased to three years as from 1949) after taking a medical qualification, and of having held the requisite resident surgical posts during a part of that time. Candidates for the final examination in ophthalmology or otolaryngology must have been qualified for three years and must have held general and specialist resident posts during an aggregate period of eighteen months. The primary examination is held in January and July; and the final examination is held in May and November. The college also grants a fellowship in dental surgery, for which there is a primary examination in applied anatomy, and applied physiology and the principles of pathology, with special reference to the teeth and jaws, and a final examination in surgery, oral pathology and bacteriology, and dental surgery. Copies of the new regulations and full particulars may be obtained from the examinations secretary, Examination Hall, Queen Square, London, W.C.1.

Medical graduates who have been registered, or eligible for registration, for at least three years may apply for examination for membership of the Royal College of Obstetricians and Gynæcologists (M.R.C.O.G.). Particulars of the regulations may be obtained from the secretary, Royal College of Obstetricians and Gynæcologists, 58, Queen Anne Street, London, W.1.

The fellowship (F.R.C.O.G.) is granted to members who are judged by the council to have advanced the science and art of obstetrics and gynæcology.

Graduates may become members of the Royal College of Physicians of Edinburgh (M.R.C.P.E.) on passing an examination, particulars of which may be obtained from the secretary, 9, Queen Street, Edinburgh, 2.

The fellows are selected from among the members by the council of the college, and receive the designation F.R.C.P.E.

Fellowship of the Royal College of Surgeons of Edinburgh (F.R.C.S.E.) is granted to medical graduates who pass the required examinations. Under new regulations which come into force at the beginning of next year the examination will be divided into two parts—the first on anatomy and physiology and on pathology and bacteriology, and the second on the principles and practice of surgery and on one of four special subjects to be chosen by the candidate. Unsuccessful candidates who appeared for examination on or before March 15 this year may still elect to be examined under the existing regulations. Particulars of the regulations may be obtained from the clerk of the college, Surgeons' Hall, 18, Nicolson Street, Edinburgh.

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a fellowship registrable by the G.M.C. as an additional qualification (F.R.F.P.S.G.). Admission is by examination and subsequent election. The candidate may be examined in either medicine or surgery; and for both examinations new regulations will come into force on June 1, 1949. From this date candidates for the fellowship in medicine must have been in possession of a recognised medical qualification for not less than three years, and must have been engaged during one of these years in full-time clinical work in a recognised hospital and have spent two other postgraduate years in medical work approved by the faculty. Candidates for admission to the fellowship in surgery will be required to possess a recognised medical qualification and to pass a primary and a final examination. For admission to the final examination candidates must have been in possession of a recognised medical qualification for not less than three years and produce evidence that they have been engaged, after qualifying, for one year in full-time clinical work in a hospital approved by the council and for a further two years in the study of surgery or its allied sciences. Alternatively, candidates may submit themselves for examination in one of the following subjects: obstetrics and gynæcology, ophthalmology, or otorhinolaryngology. Details may be had from the secretary of the Royal Faculty of Physicians and Surgeons, 242, St. Vincent Street, Glasgow, C.2.

Membership of the Royal College of Physicians of Ireland (M.R.C.P.I.) is granted on the result of an examination, the details of which may be obtained from the registrar of the college, 6, Kildare Street, Dublin.

Fellows are elected by ballot from among the members, and receive the designation F.R.C.P.I.

Graduates seeking the fellowship of the Royal College of Surgeons in Ireland (F.R.C.S.I.) must pass in two examinations, a primary in anatomy, physiology, and the principles of pathology, and a final in surgery. Further particulars may be obtained from the registrar, the Royal College of Surgeons in Ireland, Dublin.

The Faculty of Radiologists offers a fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at an approved hospital, hold a radiological diploma, and have practised radiology exclusively for at least three years after obtaining that diploma. Candidates are required to pass an examination and submit a thesis. Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology. Full particulars may be obtained from the warden, the Faculty of Radiologists, 45, Lincoln's Inn Fields, London, W.C.2.

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned.

Public Health

A diploma in public health (D.P.H.) is granted by the English conjoint board, and by all the universities of the United Kingdom, except Oxford, Cambridge, and Sheffield.

Courses for the D.P.H., suspended during the war, have n resumed in most places, with curricula revised to et the new G.M.C. requirements.

ychological Medicine

The universities of London, Durham, Leeds, Man-ester, Bristol, Edinburgh, Belfast, Ireland (National iversity), and the English and Irish conjoint boards er diplomas in psychological medicine. (The Univer-y of London also grants a diploma in psychology, ken chiefly by social workers.) The courses for the ploma have not all been resumed.

diology

The Faculty of Radiologists grants a fellowship F.R.), which has already been mentioned. The univer-ties of London, Bristol, and Edinburgh and the English njoint board offer two diplomas: one in medical diodiagnosis (D.M.R.D.) and one in medical radio-erapy (D.M.R.T.). The London University course sts two years; the Bristol and Edinburgh courses for e D.M.R.D. last eighteen months, and for the D.M.R.T. wo years. The M.RAD. of Liverpool University is nted in either radiodiagnosis or radiotherapy after a wo-year course.

ropical Medicine

A diploma in tropical medicine and hygiene (D.T.M. & H.) s granted by Liverpool University jointly with the iverpool School of Tropical Medicine, by the University f Edinburgh, and by the English conjoint board. ourses are held at the Liverpool School of Tropical edicine, at Edinburgh, and at the London School of ygiene and Tropical Medicine.

ynæcology and Obstetrics

Medical graduates who are on the British Register, or ligible for registration on it, may apply to the Royal ollege of Obstetricians and Gynæcologists for examina-ion for the diploma in obstetrics (D.OBST.). The Univer-ty of Dublin also offers a diploma (D.G.O.) for which ourse is held at Trinity College; candidates spend six onths as residents in one of the three Dublin maternity ospitals. The Mastery of Midwifery granted by the ociety of Apothecaries of London has already been entioned.

phthalmology

The English and Irish conjoint boards issue a diploma n ophthalmology (D.O.M.S.). The final examination for he F.R.C.S. may be taken in ophthalmology. Examina-tions for the D.O. of Oxford University will cease after he end of this year.

aryngology and Otology

The English conjoint board offers a diploma (D.L.O.) or those who have made a special study of the ear, nose, harynx, and larynx. The final examination for the R.C.S. may be taken in otolaryngology.

næsthetics

The English and Irish conjoint boards offer diplomas n anæsthetics (D.A.). Candidates must have special xperience in giving anæsthetics.

hild Health

Diplomas in child health (D.C.H.) are granted by the nglish and Irish conjoint boards; also by the National niversity of Ireland, with a course at University ollege, Dublin.

Tuberculous Diseases

Examinations for the diploma in tuberculous diseases (T.D.D.) of the University of Wales have been resumed.

Bacteriology

Diplomas in bacteriology are granted by the universities of London and Manchester. Courses held at the London School of Hygiene and Tropical Medicine and at Manchester begin in October and last one academic year.

Clinical Pathology

The University of London offers a diploma in clinical pathology (D.C.P.) for which a year's course of study is required.

Physical Medicine

The English conjoint board offers a diploma in physical medicine (D.PHYS.MED.). Candidates must have held a registrable qualification for two years, and must have had two resident appointments occupying not less than a year.

Orthopædics

Liverpool University offers the degree of M.CH.ORTH.; the course for it lasts fifteen months.

Industrial Medicine

The University of Edinburgh, the Society of Apothecaries of London, and the English conjoint board offer diplomas in industrial health (D.I.H.). Courses are held at Edinburgh and Glasgow, and by the Society of Apothecaries of London and the Royal Institute of Public Health and Hygiene.

DENTAL DEGREES AND DIPLOMAS

There are schools of dentistry at the universities of London, Durham, Birmingham, Liverpool, Manchester, Leeds, Sheffield, Bristol, Glasgow, St. Andrews, Belfast, and Dublin; and at the University Colleges of Dublin and Cork, in the National University of Ireland. London University offers a B.D.S. and an M.S. in dental surgery; it also prepares students for the L.D.S. of the Royal College of Surgeons. This college has lately instituted a fellowship in dental surgery (F.D.S.). St. Andrews offers a B.D.S. Leeds grants a diploma (L.D.S.), a baccalaureate degree (B.CH.D.), and mastership (M.CH.D.). Glasgow University and the University Colleges of Dublin and Cork grant a B.D.S. and a M.D.S., and Trinity College, Dublin, offers a B.DENT.SC. and a M.DENT.SC. All the other universities mentioned offer L.D.S., B.D.S., and M.D.S.; St. Andrews offers a diploma in public dentistry (D.P.D.) in addition. Licences in dentistry are granted by the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland. The Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow confer a higher diploma in dental surgery.

THE MEDICAL WOMEN'S FEDERATION

ALL qualified medical women are eligible as members of the Medical Women's Federation, which has active local associations all over the country and in Northern Ireland, as well as a large London association and an overseas association linking up members all over the world. The federation is non-political. It provides medical meetings for its members and publishes a quarterly journal reviewing subjects of special interest to women doctors. These naturally cover a wide tract of social medicine, including maternity and child welfare, women in industry, the care of children and of difficult and delinquent children, the management of nursery schools and day-nurseries, women in prisons, children in approved schools and remand homes, the illegitimate child, and many related subjects. Advances in obstetrics and gynæcology, and psychological studies of women and children are also naturally of special interest to women doctors; and recent work in these branches of medicine is reviewed in the journal. From time to time the federation undertakes social studies and publishes the results. It is also able to protect the interests of its members by presenting arguments in any cases where there has been discrimination against women doctors.

The Defence Services

Royal Naval Medical Service

Medical officers are now admitted to the Royal Navy on a short-service engagement of four years or, in the case of National Service candidates who do not wish to serve for this period, are granted temporary commissions in the Royal Naval Volunteer Reserve. Candidates must have had at least six months' experience in a house-appointment. At present no women medical officers are employed. Candidates for the Royal Naval Dental Service are also entered on short-service engagements of four years.

Opportunities are given to medical and dental officers during their temporary service or short-service engagement to apply for transfer to the permanent service. Copies of regulations and forms of application may be had from the Medical Department of the Navy, Queen Anne's Mansions, St. James's Park, London, S.W.1.

Royal Army Medical Corps

Direct applications are now invited for short-service Regular Army commissions in the R.A.M.C. for a period of eight years of which the first four years will be on the active list of the Army and the remainder on the Regular Army reserve of officers. Appointment will be in the rank of lieutenant. Candidates must be: (1) normally not over 30 years of age, (2) British subjects whose parents are British subjects, and (3) registered under the Medical Acts in force in Great Britain and Northern Ireland. Such officers will, during the last fifteen months of service on the active list, be considered for appointment to a permanent Regular Army commission. If they do not desire or are not selected for a permanent commission they will, on completion of their four years' short service on the active list, receive a gratuity of £600. Full conditions of service and forms of application can be obtained on application in writing to the Assistant Director-General, Army Medical Services (A.M.D.1), 38, Hyde Park Gate, London, S.W.7. On the nomination of the Central Medical-War Committee doctors are appointed to emergency commissions in the rank of lieutenant. During their period of service they can apply for a short-service Regular Army commission, and they can be subsequently considered for a permanent commission under the conditions already outlined.

ROYAL ARMY DENTAL CORPS

Direct applications for Regular commissions in the Royal Army Dental Corps are not being invited at present. On the nomination of the Ministry of Health dental surgeons are appointed to emergency commissions with the rank of lieutenant. Such officers may apply at once for Regular short-service commissions under existing regulations, and if selected are eligible for appointment, at any time, to a permanent Regular Army commission. Candidates for short-service commissions must be not over 35 years of age, and they must be British subjects whose parents are British subjects; they must also possess a degree or licence in dental surgery of a British university or recognised licensing body, and be registered under the Dentists Act in force in Great Britain and Northern Ireland and undertake to remain so registered throughout their service. If they do not desire or are not selected for a permanent commission they will, on completion of their four years' short service on the active list, receive a gratuity of £500. Immediately on qualification dental surgeons wishing to enter the Royal Army Dental Corps should notify the Secretary, Ministry of Health, Whitehall, London, S.W.1.

Royal Air Force Medical Branch

A scheme to grant short-service commissions to registered medical men of British nationality who wish to serve in the R.A.F. Medical Branch, or who wish to re-enter the Service, has now been approved. By its terms doctors under 30 years of age on application (for the next few years the age will be 32) will be considered for the grant of commissions for a period of four years on the active list, followed by a period of four years on the reserve. During his service on the active list a medical officer will be considered for the grant of a permanent commission. Should he not be selected a permanent commission he will be eligible for a gratuity of £600 on completion of four years' active-list service on the short-service commission.

The rank on entry will normally be that of flying officer, but allowance will be made for the full period of any previous service as a medical officer in the Royal Navy the Army, the R.A.F., or the Indian Medical Service. There are also provisions under which entrants may first engage in a whole-time postgraduate appointment in a recognised hospital, or complete such an appointment if already held; in either case the period of the appointment, up to a maximum of one year, will count towards seniority in the rank of flight lieutenant. Similarly, an entrant who has previously held such a postgraduate appointment may receive an antedate of his commission equivalent to the period of the appointment, but not exceeding one year. Accepted applicants will be required to serve in any part of the world and will be required pass an examination by a Service medical board to assess their fitness to do so, and also their fitness to fly as passengers. Further particulars can be obtained on application to the Under-Secretary of State for Air (D.G.M.S.), Awdry House, Kingsway, London, W.C.2.

R.A.F. DENTAL BRANCH

Short-service commissions for a period of four years in the Dental Branch of the R.A.F. are now available to qualified dental surgeons. Officers holding short-service commissions will be eligible for selection for permanent commissions. Those not selected will receive a gratuity on completion of their short-service engagement. Further information may be obtained on application to the Under-Secretary of State for Air (D.G.M.S.).

Health Services at Home

PUBLIC HEALTH

THE introduction of the National Health Service has no direct effect on the duties of the medical officer of health in environmental hygiene. These responsibilities have evolved over the last hundred years from the basic sanitary services introduced with difficulty and by slow stages at the instigation of the first M.O.H.s. Originally the M.O.H. was closely concerned with the detailed execution of all this sanitary work, but the passage of years has led to the general acceptance of much that was originally secured with difficulty and spasmodically by his express personal intervention. Health departments are now organised to allow the M.O.H. freedom from much detailed work which can be effectively performed by trained lay officers or even transferred to the care of other departments, as in water-supply and sewage disposal. Naturally the extent of this devolution of responsibility varies widely. Rural water-supplies and sanitation remain a constant concern of the M.O.H. The supervision of housing conditions, again mainly through sanitary inspectors, is a health-department responsibility. All this work must remain under the general control of the M.O.H., and he must also supervise the quality of water-supplies even though their production is not his concern. Though less concerned personally with detailed sanitary work, he now supervises a far wider field than his predecessor of a hundred years ago.

Control of infectious diseases has always been one of the main concerns of the M.O.H. The old emphasis on isolation has now been replaced by the provision of modern hospital treatment, but there remains the active home follow-up. Bacteriologists have made great advances in the identification of different strains within certain of the pathogenic species, and these new techniques applied to epidemic control, have given the M.O.H. an instrument of precision in much of his epidemiological work. The application of specific prophylactic measures against various of the acute infections is now a major function of health departments; and already the control of such diseases as diphtheria and enteric fever is in sight.

The National Health Service Act has profoundly affected the work of the M.O.H.s of counties and county boroughs—local health authorities as they now are ıey have ceased to hold any responsibility for adminiration of hospitals, except that some individuals are embers of hospital management-committees. During e last nineteen years hospital administration has cupied the time of these M.O.H.s in some sense at the pense of preventive medicine in which they have been ecially trained. Nevertheless it will rest very largely ith them to secure close coördination of hospital and eventive services at the management-committee level; déed their influence at this point is crucial. No other edical men will be so well placed to survey the whole eld of medical activity in an area. Local health ıthorities have now formulated schemes, under part 3 the Act, for the provision of clinic and other services r mothers and preschool children, domiciliary midwifery, ealth visiting, home nursing, immunisation and vacnation, ambulances, care and aftercare, and domestic elp; and some have preliminary schemes for health entres. This is a far more comprehensive range of ersonal health services than previously existed, especially hen the increased scope of the School Health Service nder the last Education Act is associated with it. he M.O.H. is the officer on whom the administration f these services falls. Their complexity and the need or local knowledge in day-to-day administration has ed most counties to devise schemes of divisional dministration which are of particular importance o the student because of their effect on the path of ntry to the public-health service, especially where livisional county posts are combined with the office f M.O.H. to one or more county districts.

The mode of entry to the service will probably not, s in the past, be through the clinical side but through ssistant administrative posts concerned with control f infectious diseases and organisation of clinic services. Thus there will be far less likelihood of medical officers who have taken postgraduate qualifications in public ealth devoting the rest of their professional lives to linical work in a limited field. The very fact that hose who undertake clinical preventive work will also e engaged in curative work will bring the administrative nedical officer responsible for the organisation of clinic ervices into far closer contact with his professional olleagues. It is probable that experienced general ractitioners will play an increasing part in the clinic ervices of local health authorities. For many years here will, of course, be whole-time officers engaged in linic work, but it does seem likely that the publicealth officer of the future will be usually concerned with rganisation rather than with routine clinic duties. This edistribution of work coupled with the provision of ealth-centre buildings for general practice by local ealth authorities should help to produce an ever closer ssociation between M.O.H. and general practitioner— voluntary association arising from a knowledge of the elp each can give the other.

The curriculum for the diploma in public health now rovides a first part which is suitable for men engaged n tuberculosis or venereal-diseases work; a certificate is iven to those who pass the examination for part 1 only. The course for part 2 provides for those who intend to take the diploma and enter the public service. Possession of a D.P.H. is necessary for anyone now seeking appointment as a medical officer of health.

INDUSTRIAL MEDICAL SERVICES

THE term "industry" includes not only work in tories but also that in mines and quarries, transport dertakings, agriculture, and fisheries. The industrial edical services are at present unevenly developed, but re is growing realisation that the health of industrial rkers should be safeguarded in their work-places as ll as in their homes. The reasons for this recognition not wholly altruistic, for it is now recognised that tput depends on the health and wellbeing of the rkers. In this period of transition it is not possible forecast the final form of the industrial medical vices, but it is likely that they will be integrated with National Health Service. In any case, many doctors the future will find their life's work in industrial or cupational medicine. University chairs devoted to e subject have been set up at Manchester and Durham, d readerships at Glasgow and Edinburgh. The chairs of social medicine at Oxford and Birmingham also include industrial medicine within their terms of reference, and students are likely to hear more about this subject in their undergraduate courses. Postgraduate courses are held from time to time in London, Birmingham, Sheffield, and Manchester. Diplomas in industrial health have recently been instituted by the Society of Apothecaries, the Conjoint Board of the Royal Colleges of Physicians and Surgeons, Edinburgh University, and the Faculty of Physicians and Surgeons of Glasgow.

Several Government departments deal with various aspects of the industrial medical services. For instance the Post Office, which employs more workers than any other department, has had a medical service since 1855; and since it deals with engineering and manual workers in addition to office staffs, it is partly an industrial medical service. The Ministry of Fuel and Power has a mines medical service, described below, which is responsible for the health of miners; in addition, the newly formed Coal Board is setting up its own medical service. The Ministry of Supply has a staff of medical officers which deals mainly with the health of workers in the Royal ordnance factories. The Silicosis and Asbestosis Medical Board, which used to deal with the diagnosis and certification for compensation of cases of silicosis, asbestosis, and some other forms of pneumoconiosis, has now been taken over by the Ministry of National Insurance. At present there are 20 whole-time medical officers, who carry out these functions in addition to making pre-employment and periodical medical examinations of workers in certain industries liable to produce silicosis and asbestosis. The organisation is being rearranged to comply with the functions of the Ministry under the Industrial Injuries Act, which came into force this year. A separate board consisting of 3 doctors was set up in Manchester in 1941 to supervise cotton-workers who develop byssinosis and to issue compensation certificates.

FACTORY DEPARTMENT

The main Government department supervising the health of industrial workers is the Factory Department of the Ministry of Labour and National Service. This department, which dates from 1833, administers the Factories Act, 1937, with its regulations on accident and sickness prevention, hours of work, amenities, first-aid and ambulance rooms, and canteens. The staff numbers about 350, of whom 16 are medical inspectors. All members of the department, whether lay or medical, take part in activities directed towards preventing illnesses and maintaining the health of the factory population. The medical inspectors are stationed in London, Birmingham, Sheffield, Liverpool, Bristol, Manchester, Glasgow, Leeds, and Wolverhampton, and from these centres they are able to deal with factory health and conditions in any part of the country. Under them 1750 general practitioners give part-time service as factory examining surgeons, examining all young entrants into industry, and periodically all those engaged in specified dangerous processes.

WORKS MEDICAL OFFICERS

At the end of 1945 there were 143 whole-time and 903 part-time factory officers. Compared with the 1943 figures, there were 33 fewer whole-time but 153 more part-time doctors engaged in industry. More recent figures are not available, but it can be said that the wartime expansion of factory medical services is being maintained in peace-time. At present works' doctors, except those in Government factories, are paid by private employers or firms; and the workers sometimes tend to distrust the doctors' opinions on this account. In a comprehensive medical service it should be possible to arrange that the doctor is employed by the State or by some other neutral body. Medical officers of factories who are interested in social problems have wide opportunities for their study and can also undertake the teaching of health and hygiene. They can strengthen the bonds between the factory service and the general medical and hospital services, treat accidents, reduce the chances of sepsis, follow up serious cases, and ensure that patients all return to work in the shortest time compatible with adequate treatment and reablement. Inevitably they will have to play an important rôle in the schemes for resettling disabled persons in industry. With their first-hand knowledge of the processes carried out and of the physical and mental capacities of the workers, they will be able to place the disabled persons in suitable jobs and keep them under observation.

RESEARCH

Apart from investigations and research into industrial diseases conducted by medical inspectors of factories, mines' medical officers, works' medical officers, and examining surgeons, much fundamental research into environmental conditions has been carried out by investigators of the Industrial Health Research Board of the Medical Research Council. Problems investigated include those of hours of work, lighting and vision, heating and ventilation, accident proneness, and sickness-absenteeism. The investigations have been mainly physiological and statistical, but clinical studies have also been made under the ægis of the Industrial Pulmonary Diseases Committee of the Medical Research Council, and include inquiries into the pneumoconiosis of coalminers and the byssinosis of cotton-workers. It became apparent that more clinical research into occupational diseases was needed, and the council in 1942 appointed a director of research in industrial medicine. In 1943 a department for research was established under the council at the London Hospital, and more recently, in conjunction with the Ministry of Fuel and Power, a bureau for research into pneumoconiosis among South Wales coalminers was established at Cardiff. Research into industrial-health matters is also being undertaken by the university departments mentioned above.

The Association of Industrial Medical Officers was formed some years before the war by doctors interested in industrial health, and branches have been established in various parts of the country; the *British Journal of Industrial Medicine* is sponsored by the A.I.M.O. in conjunction with the British Medical Association.

MINES MEDICAL SERVICE

THE Mines Medical Service of the Ministry of Fuel and Power since its inception in 1943 has consisted of a chief mines medical officer and his deputy at headquarters, and a medical officer in each of the eight main coal-producing regions of the country. These officers have been selected primarily on account of their experience of and qualifications for mining medical work; and by virtue of their special knowledge of the environmental factors in mines they act in an advisory and consultative capacity to the Minister of Fuel and Power and his administrative officers, H.M. inspectors of mines, mine managements, other Government departments, medical bodies, and others concerned.

The work of the mines medical officers is directed to securing that the health of the mine-workers is maintained at the highest level, particularly in relation to occupational factors. They are therefore concerned with supervision of medical arrangements (including first-aid) at mines themselves, and with ensuring that medical treatment and rehabilitation are available for mine-workers following injury or illness, and that these facilities are used to the best advantage. Where the provision of a necessary service falls short of need, it is their duty to propose improvements. They are also concerned with investigation and research into illness among miners.

During the war years, the Ministry of Fuel and Power's medical staff was necessarily concerned with certain temporary work, such as the medical aspects of recruitment and conservation of man-power. Certain permanent schemes, however, were put into effect, prominent among which is that whereby workmen who are injured at the mines, where they are often not readily accessible to a doctor, can have morphine administered to them by specially selected certificated first-aid men employed at the mines. Long-term policies were also developed, and some of these are now well established, such as the arrangements for medical examination of all entrants to coalmining below 18 years of age and the medical examination, including X ray, of all entrants, irrespective of age, to the South Wales coalfield. Another development of significance is the provision at certain mines of medical-treatment centres staffed by a State-registered nurse who will be under the direct supervision of a doctor. This scheme is already in operation at a number of mines; when it is functioning fully it will provide workers with early treatment of a very high standard.

Since Jan. 1, 1947, the National Coal Board has operated the coalmines of the country in accordance with certain statutory requirements, one of which is to secure the health of the persons they employ. To implement this requirement, the Board are in the process of engaging medical staff to advise them on matters of health and to exercise medical supervision of their employees by continuing the development of the scheme initiated by the Ministry of Fuel and Power. As the work of the National Coal Board doctors develops, the Ministry's Mines Medical Service will be freed to devote more of its attention to additional constructive work which has had to be left in abeyance while temporary but immediate problems were dealt with.

PRISONS AND BORSTAL INSTITUTIONS

AT the larger prisons whole-time medical officers are appointed, and at the most important ones principal medical officers are assisted by one or more medical officers. Salaries are in accordance with the general Civil-Service scales, and appointments are pensionable; unfurnished quarters are provided at most prisons, at a moderate rental. Preference is given to candidates with practical experience of psychological medicine and good all-round knowledge of general medicine and surgery. Appointments are made by the Civil Service Commission, 6, Burlington Gardens, London, W.1, to whom all inquiries should be addressed.

At the smaller prisons no whole-time medical officers are employed; local practitioners are usually appointed as part-time officers. Further particulars of these appointments can be obtained from the Prison Commissioners, Horseferry House, Dean Ryle Street, London, S.W.1.

Services Abroad

COLONIAL MEDICAL SERVICE

VACANCIES in the Colonial Medical Service occur most often in tropical Africa and Malaya. Medical officers must be British subjects holding medical qualifications registrable in the United Kingdom, and should have had at least twelve months' experience in hospital appointments since qualifying. Candidates for permanent service must have been born after Jan. 1, 1907, but contract appointments are also available in certain territories for doctors born before this date.

Medical officers are usually appointed in the first instance for general duties, which require all-round ability and a balanced outlook upon both preventive and curative medicine. Selected candidates may be required to take a course in tropical medicine and hygiene before proceeding overseas, or to attend such a course during their first leave. Some posts are purely concerned with public-health work, and for these the possession of a D.P.H. or some special experience in preventive medicine is necessary. There are ample opportunities for field investigation, while officers with special aptitude are encouraged to obtain such higher qualifications as will enhance their value to the Service. Officers possessing qualifications or experience in pathology would be considered for appointment to the laboratory establishment. Workers in this branch carry out pathological and chemical examinations for clinical, forensic, and public-health purposes, and also conduct researches into local problems. Specialist appointments and higher administrative posts are filled by the promotion of officers possessing appropriate qualifications and ability. There are occasional vacancies for medical women with experience in gynæcology and obstetrics, school health, and child welfare.

The total establishment of the various government medical departments amounts to about 700 European medical officers and about 1200 locally appointed medical officers. Depending upon the territory, such diseases as malaria, yaws, leprosy, sleeping sickness, plague, yellow fever, cholera, and other conditions associated with the tropics are encountered, in addition to the usual diseases of temperate climates. An officer in the Colonial Medical Service has special opportunities for the practice of preventive medicine, and there is ample scope for those interested in the clinical aspects of disease or in field research. The medical services will be considerably expanded in order to fulfil schemes for raising health standards in all colonies. Full particulars of terms and conditions of service may be obtained from the Director of Recruitment, Colonial Office, 15, Victoria Street, London, S.W.1.

SOUTHERN RHODESIA MEDICAL SERVICE

THE government of Southern Rhodesia maintains a medical and public-health service with an establishment of 19 whole-time administrative, specialist, or public-health officers and government medical officers. The rates of pay for the whole-time officers are:

	Annual salary
Secretary for Health	£1980
Director of preventive services; director of curative services	£1760
Regional medical officer of health; 2 directors of laboratories; medical superintendent, leprosy hospital; medical superintendent, mental hospital	£1485–£55–£1650
Senior schools medical officer; 2 radiologists	£1265–£55–£1650
Nutrition officer; radiologist; pathologist; psychiatrist	£1265–£55–£1430
Assistant medical superintendent, mental hospital	£1100–£55–£1265
Schools medical officer (man); 2 schools medical officers (women)	£935–£33–£1100

Government medical officers are graded as follows:

2 senior government medical officers ..	£1485–£55–£1650
48 government medical officers	£660–£27 10s.–£990

In addition to the salary scales shown, there is a cost-of-living allowance varying from £78 to £150 a year on a sliding scale. Children's allowances are also paid.

Whole-time medical officers and the two senior government medical officers are not permitted private practice but are allowed consultant practice. Government medical officers, except those stationed at Salisbury or Bulawayo, are allowed private practice, the value of which varies from £100 per annum upwards, according to the station. The duties of government medical officers include supervision of the 15 government hospitals and 76 native clinics, and attendance on police, boarders in government schools, and prisoners. They also undertake medicolegal work and public-health duties. Leave may be granted at the rate of one-eighth of service, and may be taken in periods not exceeding 184 days at a time. Study leave may also be granted. After two years' service medical officers under the age of 45 can be appointed to the fixed establishment, and contribute to a pensions scheme. The retiring age is 60. On appointment, government medical officers are usually stationed at Salisbury or Bulawayo, where they are paid an allowance of £200 per annum in compensation for not being allowed to undertake private practice. They are usually required to do relieving duties at various out-stations until appointment to a permanent post. Appointments in Great Britain to the service are made through the High Commissioner for Southern Rhodesia, Rhodesia House, 429, Strand, London, W.C.2, who will supply further details on request.

SUDAN MEDICAL SERVICE

RECRUITMENT from England of medical inspectors is at present in abeyance. It is possible that there will be vacancies in the near future for posts carrying with them certain special duties, but no information about the terms of service and the experience required is at present available.

MEDICAL MISSIONARY SERVICE

CHRISTIAN medical men and women who wish to offer their services where the need is greatest will find opportunities in medical missionary work. There are university medical schools, central and rural hospitals, and many opportunities for public-health work and research. Christian missions can claim to have given China a modern medical profession. In India and Pakistan they have helped to maintain high ethical and professional standards, and have specialised in nursing education. In Africa and other primitive regions they have pioneered rural health services and the training of subordinate staff. All over the world the work is becoming integrated with the government services though still maintaining its identity. For undergraduate candidates for the service there are hostels in London and Edinburgh, and also various scholarships. At least eighteen months or two years of resident appointments is advised for all, and special diplomas or higher degrees for some. Special missionary training is also required by some societies. Service is for terms of from two to six years according to the country and climate; there are opportunities for postgraduate study during furloughs. Offers for life service are expected, but short terms are considered. Salary is on a missionary subsistence basis with allowances, free passages and quarters, and pension provision. There are schools for missionaries' children at home and in many of the fields. Applications from students or qualified men and women should be made either to the secretary of one of the denominational or interdenominational missionary societies, or through the local branch of the Student Christian Movement or the Intervarsity Fellowship, or to the Chairman, Medical Advisory Board of the Conference of British Missionary Societies, Edinburgh House, 2, Eaton Gate, London, S.W.1.

Postgraduate Education

In London

The BRITISH POSTGRADUATE MEDICAL FEDERATION is a school of the University of London. It coöperates with the Royal Colleges and other bodies in providing for postgraduates in London, supplementing the provisions at the undergraduate medical schools and teaching hospitals. The federation includes the Postgraduate Medical School at Hammersmith Hospital, with its university departments of general medicine, general surgery, obstetrics and gynæcology, and pathology, and institutes in the principal branches of medicine associated with the special hospitals. Appointments of the house-officer and registrar types in the hospitals and institutes provide the most valuable form of postgraduate education, and there are opportunities for research by selected graduates. In addition to the Postgraduate Medical School, the institutes included in the federation are those of psychiatry, neurology, child health, ophthalmology, laryngology and otology, diseases of the chest, cardiology, orthopædics, dermatology, urology, and dental surgery. These are in various stages of development, and the numbers of students that can be admitted to the clinical practice of some of the hospitals are limited. At all the institutes courses of instruction are given throughout the academic year; they are suitable for graduates in the early stages of their specialist education and also for those who have completed their practical training. Two or more years of hospital work in general medicine and general surgery after graduation are normally advisable before commencing work in the special branches. The work at the institutes is of an advanced type and is sufficiently comprehensive to enable graduates with suitable practical experience to prepare for higher degrees and diplomas. Emphasis is placed on clinical and laboratory teaching, supplemented by lectures and demonstrations.

The *Postgraduate Medical School of London* is associated with the Hammersmith Hospital, Ducane Road, W.12. The teaching in the clinical departments, based on ward work, is continuous and is supplemented by lectures during three ten-week sessions starting in January, April, and October.

with adequate treatment and reablement. Inevitably they will have to play an important rôle in the schemes for resettling disabled persons in industry. With their first-hand knowledge of the processes carried out and of the physical and mental capacities of the workers, they will be able to place the disabled persons in suitable jobs and keep them under observation.

RESEARCH

Apart from investigations and research into industrial diseases conducted by medical inspectors of factories, mines' medical officers, works' medical officers, and examining surgeons, much fundamental research into environmental conditions has been carried out by investigators of the Industrial Health Research Board of the Medical Research Council. Problems investigated include those of hours of work, lighting and vision, heating and ventilation, accident proneness, and sickness-absenteeism. The investigations have been mainly physiological and statistical, but clinical studies have also been made under the ægis of the Industrial Pulmonary Diseases Committee of the Medical Research Council, and include inquiries into the pneumoconiosis of coalminers and the byssinosis of cotton-workers. It became apparent that more clinical research into occupational diseases was needed, and the council in 1942 appointed a director of research in industrial medicine. In 1943 a department for research was established under the council at the London Hospital, and more recently, in conjunction with the Ministry of Fuel and Power, a bureau for research into pneumoconiosis among South Wales coalminers was established at Cardiff. Research into industrial-health matters is also being undertaken by the university departments mentioned above.

The Association of Industrial Medical Officers was formed some years before the war by doctors interested in industrial health, and branches have been established in various parts of the country; the *British Journal of Industrial Medicine* is sponsored by the A.I.M.O. in conjunction with the British Medical Association.

MINES MEDICAL SERVICE

THE Mines Medical Service of the Ministry of Fuel and Power since its inception in 1943 has consisted of a chief mines medical officer and his deputy at headquarters, and a medical officer in each of the eight main coal-producing regions of the country. These officers have been selected primarily on account of their experience of and qualifications for mining medical work; and by virtue of their special knowledge of the environmental factors in mines they act in an advisory and consultative capacity to the Minister of Fuel and Power and his administrative officers, H.M. inspectors of mines, mine managements, other Government departments, medical bodies, and others concerned.

The work of the mines medical officers is directed to securing that the health of the mine-workers is maintained at the highest level, particularly in relation to occupational factors. They are therefore concerned with supervision of medical arrangements (including first-aid) at mines themselves, and with ensuring that medical treatment and rehabilitation are available for mine-workers following injury or illness, and that these facilities are used to the best advantage. Where the provision of a necessary service falls short of need, it is their duty to propose improvements. They are also concerned with investigation and research into illness among miners.

During the war years, the Ministry of Fuel and Power's medical staff was necessarily concerned with certain temporary work, such as the medical aspects of recruitment and conservation of man-power. Certain permanent schemes, however, were put into effect, prominent among which is that whereby workmen who are injured at the mines, where they are often not readily accessible to a doctor, can have morphine administered to them by specially selected certificated first-aid men employed at the mines. Long-term policies were also developed, and some of these are now well established, such as the arrangements for medical examination of all entrants to coalmining below 18 years of age and the medical examination, including X ray, of all entrants, irrespective of age, to the South Wales coalfield. Another development of significance is the provision at certain mines medical-treatment centres staffed by a State-register nurse who will be under the direct supervision of doctor. This scheme is already in operation at a numl of mines; when it is functioning fully it will prov workers with early treatment of a very high standard.

Since Jan. 1, 1947, the National Coal Board operated the coalmines of the country in accordar with certain statutory requirements, one of which to secure the health of the persons they employ. implement this requirement, the Board are in the proc of engaging medical staff to advise them on matters health and to exercise medical supervision of th employees by continuing the development of the sche initiated by the Ministry of Fuel and Power. As t work of the National Coal Board doctors develops, t Ministry's Mines Medical Service will be freed to dev more of its attention to additional constructive wo which has had to be left in abeyance while temporary b immediate problems were dealt with.

PRISONS AND BORSTAL INSTITUTIONS

AT *the larger prisons* whole-time medical officers a appointed, and at the most important ones principal me cal officers are assisted by one or more medical office Salaries are in accordance with the general Civil-Servi scales, and appointments are pensionable; unfurnish quarters are provided at most prisons, at a modera rental. Preference is given to candidates with practic experience of psychological medicine and good all-roun knowledge of general medicine and surgery. Appoin ments are made by the Civil Service Commissio 6, Burlington Gardens, London, W.1, to whom a inquiries should be addressed.

At the smaller prisons no whole-time medical officer are employed; local practitioners are usually appointe as part-time officers. Further particulars of these appoint ments can be obtained from the Prison Commissioner Horseferry House, Dean Ryle Street, London, S.W.1.

◆

Services Abroad

COLONIAL MEDICAL SERVICE

VACANCIES in the Colonial Medical Service occur mo often in tropical Africa and Malaya. Medical offic must be British subjects holding medical qualificati registrable in the United Kingdom, and should have h at least twelve months' experience in hospital appoi ments since qualifying. Candidates for perman service must have been born after Jan. 1, 1907, b contract appointments are also available in certai territories for doctors born before this date.

Medical officers are usually appointed in the fir instance for general duties, which require all-roun ability and a balanced outlook upon both preventi and curative medicine. Selected candidates may b required to take a course in tropical medicine and hygiene before proceeding overseas, or to attend suc a course during their first leave. Some posts are pur concerned with public-health work, and for these th possession of a D.P.H. or some special *experience* preventive medicine is necessary. There are amp opportunities for field investigation, while officers w special aptitude are encouraged to obtain such hig qualifications as will *enhance their* value to the Servi Officers possessing qualifications or experience in pat logy would be considered for appointment to the labo tory establishment. Workers in this branch carry o pathological and chemical examinations for clinica forensic, and public-health purposes, and also condu researches into local problems. Specialist appointments and higher administrative posts are filled by th promotion of officers possessing appropriate qualificati and ability. There are occasional vacancies for medica women with experience in gynæcology and obstetric school health, and child welfare.

The total establishment of the various governmen medical departments amounts to about 700 Europea medical officers and about 1200 locally appointed medi instruction are given in this course, 100 of which are devoted to practical work; in connexion with it a series of 12 open lectures are given by leading authorities in their various specialties. The course in midwifery and gynæcology which began in July is constructed primarily for those who already have considerable experience in this specialty and are preparing for the M.R.C.O.G. Two courses in internal medicine, lasting 12 weeks, are held, starting in April and October of each year. These classes comprise lectures, lecture-demonstrations, clinical teaching, and clinical pathological demonstrations; they are suitable for graduates wishing to specialise in medicine or who require a refresher course in the current outlook on internal medicine. Two courses in general surgery are held each year, starting in March and October. These courses are of 4½ months' duration; they include lectures on surgical anatomy, surgical pathology, and selected surgical subjects, as well as clinical demonstrations and ward visits for the class in small groups. In addition to the Edinburgh Royal Infirmary, other general and special hospitals in the city coöperate in the provision of clinical teaching facilities. General practitioners' courses have been completely reorganised with the teaching either at the bedside or by means of lecture demonstrations. Emphasis is laid on recent advances in treatment, and free discussion as well as constructive criticism by members of the course is encouraged. The course held in May, 1948, was attended by 52 practitioners. Open postgraduate lectures of wide interest are organised in conjunction with the courses in surgery and medicine. An increasing number of overseas graduates are attending these courses and it is the intention of the board to provide a hall of residence as soon as possible. Courses are often booked up several months in advance, so those intending to apply should do so at an early date. Applicants should write, giving particulars of their medical qualifications and postgraduate experience, to the Director of Postgraduate Studies, University New Buildings, Edinburgh, 8.

GLASGOW UNIVERSITY offers full-time intensive postgraduate courses in medicine and surgery twice a year. The courses run concurrently, are each of eight weeks' duration, and begin in mid-April and mid-October. These courses consist of clinical meetings, pathological demonstrations, and lectures: they are primarily designed for candidates training for the higher qualifications in medicine and surgery. A short full-time intensive course in pædiatrics will be conducted from Sept. 6 to 17. Courses in ophthalmology, dermatology, and other specialties are organised when the demand arises, and are advertised from time to time in the medical journals. Recognised training in diagnostic and therapeutic radiology is also available.

For general practitioners refresher courses of a fortnight's duration are held four times a year: they consist mainly of clinical demonstrations, but include also a few lectures on modern therapy. The next course will be held in the latter part of September. All inquiries should be addressed to the Director of Postgraduate Medical Education, The University, Glasgow, W.2.

Some Special Courses

MEDICINE

The *Royal College of Physicians of London* holds a series of advanced postgraduate lectures, including some on pathology, biochemistry, &c. They are given four times a week apart from vacations. The lecturers are drawn from the provinces as well as London. The audience is limited to 200. Details can be obtained from the Secretary of the College, Pall Mall East, London, S.W.1.

SURGERY

The *Royal College of Surgeons of England* has arranged a number of lectures and demonstrations to be held at the college. In surgery two series, each of 12 lectures, will be given during October and April. In anæsthesia two series, each of 45 lectures, will be given during October–November and March–April; in addition, tutorial classes will be held. Two series in orthopædic surgery, each of 12 lectures, will be given during January and July. Between October and January, and also between March and May, there will be a series of 72 lectures and practical demonstrations in anatomy, applied physiology, and pathology. Lectures in oral, dental, and general surgery will be held in September and February–March; and lectures and practical demonstrations on the application of the basic sciences to dental surgery will be held in July and January–February. The college maintains a library, museums, and laboratories for the use of medical graduates from all parts of the world. Fellows and members enjoy these facilities by right, but they have also been made open, on suitable introduction, to other graduates of medicine, and to undergraduates. The Arris and Gale and the Hunterian lectures provide opportunities for the presentation of original work in anatomy, physiology, pathology, and surgery. The college awards several prizes for meritorious work, and fellowships for those who wish to engage in practical work or research. From next January residential accommodation will be provided for postgraduate students within the college.

At *St. Mark's Hospital*, City Road, London, E.C.1, surgeons wishing to specialise in proctology may attend a six-month course, and postgraduate students working for higher degrees may come for 1–4 weeks' whole-time study. Intensive courses, each lasting one week, are held in conjunction with the Fellowship of Postgraduate Medicine three or four times a year.

The *Royal College of Surgeons in Ireland* holds a two-month full-time course in surgery, beginning in April of each year. A one-year course has been instituted in anatomy, physiology, and pathology, as a preparation for the primary fellowship examination.

OBSTETRICS AND GYNÆCOLOGY

The *Combined Postgraduate Teaching School* of Queen Charlotte's Maternity Hospital and the Chelsea Hospital for Women was formed two years ago to make available postgraduate teaching in obstetrics and gynæcology at the two hospitals. Refresher courses have been held regularly at each hospital; and twice a year there have been intensive courses for those studying for the M.R.C.O.G. examination. In addition, postgraduates have been able to attend the practice of Queen Charlotte's Hospital for periods of from 1 to 4 weeks. From Oct. 1 the Combined Postgraduate Teaching School, in conjunction with the Postgraduate Medical School of London, is forming an Institute of Obstetrics and Gynæcology, under the British Postgraduate Medical Federation.

PUBLIC HEALTH

Most university courses in public health have now been revived. New requirements by the G.M.C. have caused universities to revise the course for this examination, which is now taken in two parts, the first leading to a certificate in public health (C.P.H.), taken after three months' work, and the second to the diploma. The *London School of Hygiene and Tropical Medicine* offers a course beginning in October and lasting nine months, and designed primarily for those intending to seek posts as medical officers of health. All vacancies for the full course for the diploma have been filled, and there is a waiting-list, but in view of the development and subdivision of medical work in the public-health service, some places in the course for the certificate have been reserved for doctors who intend to undertake public-health work other than that of a M.O.H. The *Royal Institute of Public Health and Hygiene* also offers courses for the diploma, conforming to the new regulations; the next course begins on Oct. 1.

PSYCHOLOGICAL MEDICINE

Courses for the diploma in psychological medicine are at present in abeyance at some universities. At the *Institute of Psychiatry* in the British Postgraduate Medical Federation, based on the Maudsley Hospital and Bethlem Royal Hospital, there are lectures, lecture-demonstrations, seminars, and practical work in the laboratories covering the relevant aspects of psychology, anatomy, and physiology of the nervous system, psychiatry of children and adults, delinquency, pathology of nervous and mental disease, and related matters. The subjects of these lectures, which are given during the university terms, are grouped so as to meet the needs of postgraduate students at different stages of training.

A course for the university diploma in clinical pathology, lasting one year, is available for a limited number of selected students. The department of radiology of the hospital provides courses for the diplomas in medical radiology of the university and the conjoint board. All these courses begin in October. Long-term and short-term tuition in anæsthetics is provided for a small number of students.

The *Institute of Cardiology* is associated with the National Heart Hospital, Westmoreland Street, W.1. Six appointments of the registrar type are offered each year to physicians in training as cardiologists who already have a sound grounding in general medicine. General physicians may enrol for full-time or part-time instruction for one term of approximately three months. There are three terms annually, commencing in January, May, and October. Three intensive courses of lectures and demonstrations, each lasting a fortnight, are held in February, July, and November. Twice a year a series of weekly lectures is held, chiefly for the benefit of general practitioners.

The *Institute of Child Health* is associated with the Hospital for Sick Children, Great Ormond Street, and the Postgraduate Medical School at Hammersmith Hospital; it also has an arrangement with the Queen Elizabeth Hospital for Children, Hackney. The institute provides tuition throughout the year in three terms of three months each, commencing in January, May, and September, and in addition a series of lectures by specialists and experts in various spheres is given each term.

The *Institute of Dermatology* is associated with St. John's Hospital for Diseases of the Skin, 5, Lisle Street, W.C.2. Clinical teaching takes place in the outpatient department twice daily. There are also facilities for study and tuition in the pathological laboratory, but owing to the restricted accommodation no ward instruction is possible yet. A short course of lectures is given in the summer months, and a longer and more systematic course in the winter. Clinical assistantships are arranged for more advanced students.

The *Institute of Diseases of the Chest* is associated with the Brompton Hospital, S.W.3. Students enrol for three months or more on what is at present an approximately half-time course. In special cases a whole-time programme can be arranged. There are three terms annually, commencing in January, April, and October.

The *Institute of Laryngology and Otology* is associated with the Royal National Throat, Nose, and Ear Hospital at Gray's Inn Road and Golden Square, W.C.1. A comprehensive full-time course lasting twenty weeks is held twice a year, commencing in January and July. A part-time advanced revision course lasting 10–12 weeks, suitable for students preparing for the higher qualifications, is held twice yearly, approximately from February to May and from September to November. There are a number of appointments open to students, after completion of basic training in the specialty, which give good opportunities for acquiring and extending clinical experience.

The *Institute of Neurology* is associated with the National Hospital for Nervous Diseases, Queen Square, W.C.1. More advanced students are appointed as clinical clerks in the wards or attached to special departments and the research laboratories. Two ten-week courses, which are whole-time, are held in the autumn and spring terms.

The *Institute of Ophthalmology* is associated with the Moorfields, Westminster, and Central Eye Hospitals. In addition to teaching by means of hospital practice, a routine lecture and tutorial course, lasting 4–5 months, is held twice a year commencing in March and October. Clinical teaching and lectures are given at a higher level for advanced students.

The *Institute of Orthopædics* is associated with the Royal National Orthopædic Hospital, Great Portland Street, W.1. The practice of both the central hospital and the country branch at Stanmore is open to postgraduate students. Selected students have opportunities for taking an active part in the work of the institute and the hospital and of spending in the institute up to two years of their training. A comprehensive basic course of six months' duration is held each year, commencing in October. Twice a year, in April and September, a one-week course in advanced clinical orthopædics is held.

The *Institute of Psychiatry* is associated with the Maudsley Hospital, Denmark Hill, S.E.5. Training normally covers 2–3 years after experience elsewhere in general medicine, and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations are given throughout each of the university terms; clinical training continues throughout the year and includes seminars and case discussions. Students who, because of previous experience, do not wish to take the comprehensive two-year course will be able to attend limited series of lectures and clinical instruction. There are facilities for original investigations under supervision in the clinical departments and in the psychological, neuro-anatomical, electrophysiological, and biochemical departments.

The *Institute of Urology* is associated with the combined school of St. Peter's and St. Paul's Hospitals, Henrietta Street, W.C.2. Three courses of fourteen weeks' duration are held annually, commencing in January, *April*, and September. An intensive two-week course suitable for students taking higher examinations is held in September and March. Limited numbers of clinical assistants are appointed in January and July each year.

It is essential for prospective students to make their arrangements well in advance. Those sponsored by their universities, governments, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas, here for a relatively short time, who wish to see something of the practice of this country, are always welcome: they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them accompany them in their work and teaching. In addition, refresher courses for general practitioners are arranged at non-teaching hospitals in London and the home counties. The federation has a central administrative office at 2, Gordon Square, London, W.C.1, to which inquiries should be directed: An information bureau of postgraduate activities in London and other university centres is maintained.

The NORTH LONDON POSTGRADUATE MEDICAL INSTITUTE holds courses in advanced medicine, advanced surgery, and obstetrics and gynæcology; and instruction is given in pathology, anæsthetics, and radiodiagnosis. Clinical instruction is given at Bearsted Memorial Hospital, Chase Farm Hospital, North Eastern Hospital, North Middlesex County Hospital, and the Prince of Wales's General Hospital. During the coming academic year there will be eight-week courses in advanced medicine suitable for those taking the M.R.C.P. examination, and eight-week courses in advanced surgery suitable for those taking the F.R.C.S. examination. Further *information can be obtained on application to the dean,* Dr. J. Browning Alexander, the Prince of Wales's General Hospital, London, N.15.

The FELLOWSHIP OF POSTGRADUATE MEDICINE, which has an office at 1, Wimpole Street, London, W.1, provides general information on postgraduate work, and arranges courses of instruction as follows:

1. Weekend courses, occupying the whole of a Saturday and Sunday. These are given in various hospitals in such subjects as infectious diseases, industrial medicine, the rheumatic diseases, ear, nose, and throat diseases, *children's diseases, and clinical surgery.*
2. Courses specially suitable for, though not restricted to, candidates for the D.A., D.C.H., D.OBST.R.C.O.G., and F.R.C.S. (primary and final). These include general medicine, neurology, general surgery, proctology, midwifery, children's diseases, anæsthetics and anatomy, physiology, bacteriology, pharmacology, *and* pathology. Some are full-time courses, lasting 1–2 weeks. Others are spread over longer periods, taking place either in the mornings, afternoons, late afternoons, or evenings; they are intended particularly for postgraduates not free for full-time study.

In Scotland

The EDINBURGH POST-GRADUATE BOARD FOR MEDICINE, representing the university and the Royal Colleges of Physicians and Surgeons of Edinburgh, arranges programmes of graduate studies. Considerable development has taken place during the past year. The board now offers a comprehensive course in the medical sciences of anatomy, physiology, and pathology; 280 hours of

BRITISH MEDICAL STUDENTS' ASSOCIATION

This association was founded in 1940, and with the exception of five London hospitals its membership includes the student body of every medical school in England, Scotland, Wales, Northern Ireland, and Eire. It is a purely professional body whose sole object is to omote the interests of students, by providing a means communication between those at different universities the one hand, and with other professional organisations nd Government departments on the other.

One of the most valuable ways of fulfilling this aim in the organisation of clinical conferences, which are ld in university centres each year, and which give udents the opportunity to meet their colleagues from her schools, and to hear different teachers and see fferent hospitals. Previously organised only on a gional basis, the scope of these conferences has been tended during the past year, and in March a very ccessful national conference was held in London. second conference of this kind is to be held in Edinurgh in September. The programmes include lectures nd clinical teaching in general and special hospitals, sits to nearby centres, and social activities. An even reater achievement has been the organisation of the irst Students' International Clinical Conference, which as held this summer. Representatives of 24 countries pent a week each in London, Oxford, and Birmingham. t is hoped that this will be the first of a series held all ver the world.

The association publishes its own journal, and has epresentatives on various committees, such as those of he British Medical Association and the Scientific Film Association. It has organised exchanges with individuals and with groups of medical students abroad, and has arranged various other amenities, such as the coupon concession for white coats achieved by negotiation with the Board of Trade; through its central machinery students can obtain residencies at non-teaching hospitals during vacations.

The B.M.S.A. is now the acknowledged representative body for medical students. Its activities have, however, always been strictly confined to those calculated to promote the interests of medical students, *as medical students*. Nothing has been attempted, however desirable, which does not satisfy this condition. The uccess of the association and the greatly increased ecognition which it has achieved is largely attributable o the widening realisation of this limitation of its bjectives. Correspondence should be addressed to the ecretary of the association, B.M.A. House, Tavistock quare, London, W.C.1.

EMPIRE MEDICAL ADVISORY BUREAU

The British Medical Association has set up the Empire edical Advisory Bureau with a view to making the tay of overseas medical visitors to this country as rofitable and pleasant as possible, by welcoming them nd providing a personal advisory service. The bureau, which is at B.M.A. House, Tavistock Square, London, W.C.1, caters mainly for Dominion and Colonial medical men and women who are staying in this country for ostgraduate education or other purposes. Information s obtainable about postgraduate education and courses f study for higher qualifications; and inquirers can be ut in touch with the authorities of the teaching institutions. The visitor who wishes to see something of the atest medical work in his own specialty can be put in ouch with the appropriate experts.

A register of suitable hotels and lodgings is maintained y the bureau, and every effort is made to help visitors o solve the problem of finding somewhere to live. By ocial functions and in other ways doctors from the ominions and Colonies will be enabled to meet each ther and prominent members of the profession in this ountry. General information about travel, sports cilities, exhibitions, theatres, &c., may also be had. he bureau can be of greatest service to the visitor if he rites as long as possible in advance of arrival, giving nformation on the following lines: projected date of rrival, mode of travel, whether accompanied by wife, eriod of stay, objects of the visit, and in what ways assistance is desired. On arrival a letter of introduction from the local hon. secretary of the visitors' medical association, although not essential, would be welcome. The medical director of the bureau is Dr. H. A. Sandiford, to whom all communications should be addressed.

CHANGE-OVER IN THE CONTROL OF RADIUM

One of the effects of the National Health Service Act is that, after nearly twenty years' fine work, the National Radium Trust and the Radium Commission are coming to an end. The trust was created to augment the supply of radium (and later of radiotherapeutic apparatus) for medical treatment and to stimulate the advancement of knowledge concerning radium technique; whereas the commission's duties were to arrange for the custody, distribution, and full use of the trust's radium. It may be said that their birth in 1929 was certainly timely and their decease perhaps inevitable. The Royal Charter and the three supplemental charters under which they have worked are to be surrendered. Their duties will in future be undertaken partly by a Ministry of Health committee and partly by the regional hospital boards. Those who have shared in or witnessed the work of the commission may wonder whether there is likely to be a more practical way of organising the proper custody, equitable distribution, and full use of the radium publicly raised as a thank-offering for the King's recovery from illness than the way that was chosen. Since 1929 there has been a consistent effort to put expert opinion into direct practice in the organisation of radium therapy throughout the country, and the public have been well served by those who have willingly given their time to this end.

A wise decision was taken in 1929 to aim, not at creating a radiotherapy centre on the lines of the Institut du Radium in Paris or Radiumhemmet in Stockholm, excellent though the work of these institutions are, but to attempt the organisation of treatment throughout the country to the best practically attainable level. The first step was to set up national centres where radiotherapeutic departments of standing already existed, whose work was strengthened by the ancillary services inseparable from large general hospitals. Later, regional centres came into being as many parts of the country could not be served by the national centres. The support which the commission was able to give in putting this scheme into operation was extensive. Radium was loaned to the centres at a very low charge, they were given complete freedom to have this radium in any form which their clinical plans required, and their work was supplemented in many ways with a minimum of interference. One of the most successful features of the work of the commission was the way in which the members were brought into contact with the work of every centre by periodic visits; these were far from being mere visits of inspection for they served the dual purpose of keeping members abreast of the growing needs of the therapist and of reassuring every therapist associated with this national organisation that he had a good friend in the commission.

The criterion by which the work of the commission will be judged is whether the country would have done as well without it. To this there can be only one answer. When it began work our radium treatment lagged behind that of other countries, whereas now it bears comparison with any. The general level is high and many centres have contributed to important developments in technique which have stood the test of time. There is a fine spirit running through the radiotherapy departments of our hospitals, and, though it would be absurd to suggest that they created it, the Radium Commission has done much by fostering the conviction that the treatment of disease with radium was going to be well worth while.

At the Maudsley Hospital, Bethlem Royal Hospital, and associated hospitals and clinics, clinical training is provided throughout the year for a limited number of students in the various branches of psychiatry. Information can be obtained from the Dean, Institute of Psychiatry, Maudsley Hospital, Denmark Hill, London, S.E.5.

At *Edinburgh University* candidates for the diploma in psychiatry (D.PSYCH.) are now required to spend at least three years in approved hospitals, clinics, laboratories, and other institutions. At the end of this period they attend an intensive five-week course before examination. Intending candidates should enter their names with the dean of the faculty of medicine before starting special study.

At the *Tavistock Clinic* the psychotherapy of both adults and children as outpatients, based on analytical concepts, which has characterised the clinic's activities in the past, is being developed, and particular attention is being given to group psychotherapy. In addition to therapeutic work the clinic and the associated Tavistock Institute of Human Relations are studying techniques in preventive psychiatry. These include mothers' discussion groups, selection techniques, and techniques for improving interpersonal relations in school and industry and similar psychological and sociological procedures.

In the clinic systematic training is at present available in the child-guidance department for a limited number of psychiatrists, educational psychologists, and psychiatric social workers. Facilities for training in the adult department will be advertised later. Further information may be obtained from the Training Secretary, 2, Beaumont Street, W.1. Organised training activities in the Tavistock Institute of Human Relations will probably be resumed this autumn; further information may be obtained from the Secretary, Tavistock Institute of Human Relations, 2, Beaumont Street, W.1.

The *Institute of Psycho-Analysis*, 96, Gloucester Place, London, W.1, provides training in psycho-analytic theory and technique. The course is part-time and lasts about four years. It includes a personal analysis, attendance at lectures and seminars (held in the evenings), and clinical work done under supervision. Students are required to obtain general psychiatric experience at other clinics and hospitals, since the institute does not set out to teach all aspects of psychiatry. Completion of the course to the satisfaction of the training committee qualifies the student for election as an associate member of the British Psycho-Analytic Society. In addition to this main course designed for those intending to specialise, the institute gives briefer courses from time to time on the application of the principles of psycho-analysis to medical problems. These are advertised in the medical press.

TROPICAL MEDICINE

A diploma in tropical medicine is required by those seeking appointments in the tropics. Courses are held at the *London School of Hygiene and Tropical Medicine*, the *Liverpool School of Tropical Medicine*, and *Edinburgh University*.

MEDICAL STATISTICS

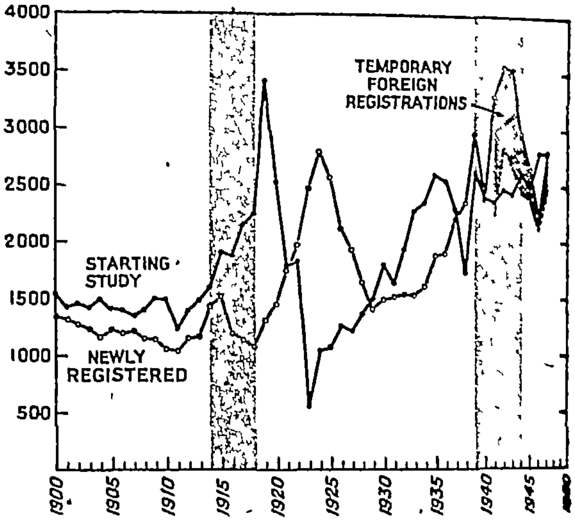
The department of medical statistics of the London School of Hygiene and Tropical Medicine offers a short course, occupying two days a week for three months, in the principles of medical statistics and statistical methods. The course is held during April to July. It may also be held during January to April if sufficient applications are received. Application should be made not less than one month before the course is due to begin to the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street (Gower Street), London, W.C.1.

INDUSTRIAL HEALTH

At *Roffey Park Rehabilitation Centre* residential courses lasting one week are held for doctors, works managers, trade-union officials, and social workers. The syllabus is divided broadly under two headings: (1) maintenance of fitness at work, and (2) rehabilitation and resettlement. Classes are modelled on the lines of the open discussion group. Inquiries should be addressed to the Secretary, Training Department, Roffey Park, Horsham, Sussex.

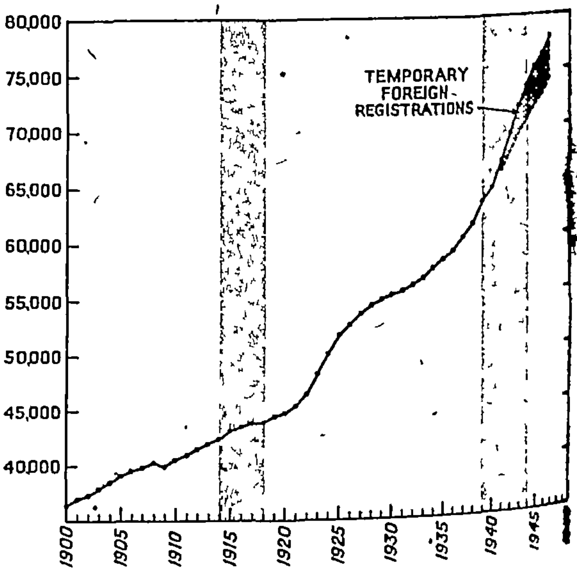
REGISTRATION

NO-ONE is a legally qualified medical practitioner unless his name appears on the Medical Register kept by the General Council of Medical Education and Registrat of the United Kingdom. The council is a standardis body, ensuring that there is a prescribed minimum of medical education and examination requirements; it is also responsible for discipline within the profession.



Numbers starting study and qualifying.*

The approximate number of second-year students admitted to medical schools in the United Kingdom and in Eire was 2498 during 1945–46, and 2793 during 1946–47; for the year 1947–48 the number was 2797. The number of newly registered in 1946 was 2237 and in 1947 was 2787. Doctors temporarily registered by virtue of Defence Regulation 32 B or of the Polish Resettlement Act, numbering 4561 (of whom about 4200 are registered under the Defence Regulation), have been enabled by the Medical Practitioners and Pharmacists Act to apply for admission to the permanent register, provided that they are resident in Great Britain. Up to the beginning of this month just over 400 had been so registered; the total number of applicants is about 1000.



Numbers on the Medical Register.

---

* The numbers shown as starting study are taken from the Medical Students' Register up to 1938; and since then from returns made by the medical schools to the General Medical Council. Both forms of registration are incomplete, but latterly returns have been received from almost all schools.

rgeons in Europe. I utilised my position to sneak p to the dissecting-room every night and occupy yself with the grisly task of dissection in the dark, r. of course, I could not employ any light. This, ou might say, was difficult, but fortunately I have lways had an extraordinary sense of smell which not nly enabled me to dissect in the dark but was to prove o useful in diagnosis in the glorious career which ubsequently opened up for me. My only book was copy of Zoroan's *Anatomy*, written in Latin, and the sk of first learning this language and then studying natomy was, at the tender age of twelve, a grim one. owever, with the image of Hippocrates constantly efore my eyes, I was inspired to lay the foundation of hat I may call, with all due modesty, a splendid and istinguished career. Besides my studies and my work s scalpel-sharpener, I was also engaged in running rands for a local eel-seller, and as you can imagine y day was full. For three years I had no sleep at all. habit which has stood me in good stead in many a ng vigil by the bedside of a patient when engaged in he desperate struggle against ensuing death.

At the age of twenty, I qualified M.D. at the University f Presbonitz, the youngest doctor in Westphalia. h, what vistas were opened up of service to humanity. f grim struggles with man's mortal enemies, with myself t last a combatant. How proud my old parents were, specially as after three years of work as a house-surgeon was appointed fifth assistant to the great Professor orben and was able to send them a cheque for two illion tonschkas (about *7s. 6d.* in English money).

Let me tell you about my first notable case.

he patient was a poor Westphalian peasant with a touching simplicity. By studying him with great care I was e to gain his confidence, a step which, as I always tell my colleagues, is essential in the successful management of any ailment, however trivial. This peasant, I'll call him Bauer, told me the whole story of his life, his work on the farm, and the careers of his seven children: and although I was forced to spend many weary hours at his bedside taking his "history," as it is called, I discovered something which even the great Professor Gorben had missed. Picture the scene; a large hospital ward filled with professors, lecturers, house-surgeons, general practitioners, and students, with Professor Gorben, "The Prof," as we affectionately called him, standing like a veritable Aesculapius among them. The Prof made a detailed examination of Bauer which took him $3\frac{1}{2}$ hours and was interspersed with much magnificent teaching. Finally he drew himself up and said, "Gentlemen, I will operate tomorrow." A deathly hush fell on the assembly, for all of them knew the seriousness of this operation, of which Gorben was the foremost exponent in e world. With my heart fluttering in my mouth but with e goal of scientific honesty before my eyes, I said, "But ofessor Gorben, ulcerative gingivitis has set in." I will t dwell on the complex discussion which followed, in which e Prof put some searching questions to me. Suffice it to y that two years later I received a hard-baked scone from , baked by Mrs. Bauer, on which was engraved, "To e Man who Saved my Life." Ten years later Bauer was pointed mayor of Presbonitz.

This hard-baked scone is still one of my most treasured ossessions, despite my extraordinary sense of smell.

* * *

Dr. X is very unorthodox in his teaching methods. fter demonstrating to some students the technique of travenous transfusion, he dashed into the clinic room nd returned triumphantly waving the largest French eedle that he could find. "Now we can practise," e chuckled. But the poor students eyed the huge needle ith fright and none of them made any move to disbe. However, without even asking for volunteers, r. X took off his white coat, rolled up his shirt sleeve, at down, and directed one of the students to vencture him, which the amazed pupil proceeded to do to the accompaniment of garrulous advice from the doctor. As soon as blood flowed, the needle was removed, and without further comment the teacher displayed his other arm for another student to tackle. Some may argue that this is carrying teaching enthusiasm too far. Other students may expect me to submit sheepishly to their attempts to lumbar-puncture me. Our genitourinary surgeon is not the only one filled with alarm lest, in these ultra-democratic days, students demand that he be the subject of their plumbing experiments. No wonder the Spens Committee recommended special remuneration for teachers.

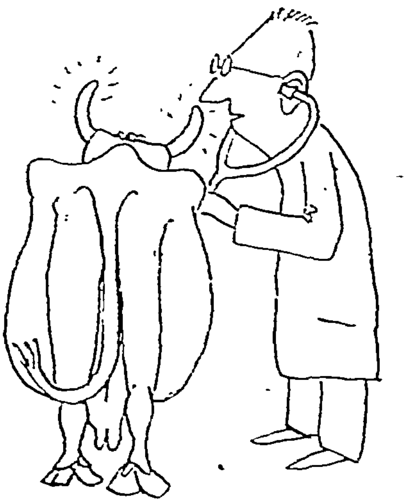
Having been called to see Billy Joe's cow (a week post partum and the nearest vet two hundred miles away), I asked what was wrong. "She's running a temperature, Doctor," was the reply. I immediately had visions of foul discharge, &c., and wondered how one would do a D and C on a cow. However, I asked what was the normal temperature of a cow and what was the temperature of my new patient. "Well, Doctor," I was told, "you tell it by the feel of its horns. They feel hot and they shouldn't." Rather shaken by this and wondering what one did in hornless breeds I went along to see the animal. There seemed to be no vaginal discharge or cough, in fact no reason at all for the pyrexia. I decided to put the cow on sulphadiazine, but what dosage? I asked what the animal weighed. "It must be about three hundred and seventy pounds dressed" was the reply. Further questioning revealed this as about five hundred pounds live weight. After some arithmetic, and allowing a bit for unknown idiosyncracies, I gave 4 g. statim, followed by 2 g. four-hourly. I also instructed the owner to wire the vet. Next day we received a reply. "Stop sulphadiazine. Give pound of Epsom salts." In my worry I had forgotten that the commonest cause of puerperal pyrexia is constipation.



My fee will be a cut from the calf, which will be ready for the table in eight weeks' time.

* * *

Medical field-work is regrettably a small and often absent feature of the life of a medical registrar, who spends most of his time cloistered in a hospital. So it was with some enthusiasm that I set out to examine the brother of a patient who has a galaxy of congenital abnormalities. The study of my patient's family, seven brothers of whom were alleged to have similar changes, was fraught with difficulties, for not only were they scattered throughout the British Isles, so the cost of financing a family reunion party for the purpose would be prohibitive, but there was no clue to their addresses. After a Herculean effort I had made contact with this one relation.

As I entered the small urban dwelling I felt a slightly suspicious atmosphere and soon retired with the brother upstairs. The objects of my search were the fingernails, the patellæ, and the buttocks. With great self-control the various systems were routinely examined, and when eventually I laid a hand on his glutei my heart was filled with the joy of a collector as I detected the rare bony anomaly again.

On returning to the parlour I found myself surrounded by slightly hostile potential clinical material in the form of five young daughters, so I ventured to suggest that I made further examinations on the family, the exact nature of which I did not disclose. Chaos

IN ENGLAND NOW

A Running Commentary by Peripatetic Correspondents

AT that Mecca of Methodism, the Central Hall, Westminster, during the past fortnight hundreds of psychologists, male and female, young and old, from many nations, have been swarming up the big staircase to the International Congress on Mental Health, and the lobbies and hall have been a veritable Tower of Babel. Nothing could have contrasted more—or could it ?—with the aquarium which used to stand on this site or with the rather naughty music-hall which was here before that. Speakers in the discussions, trying to cram long papers into the allotted five minutes, were the bane of the smart young lady and the gentleman who gave a running translation for the benefit of the French-speaking psychologists. It was interesting how these psychologists had to soothe their nerves after speaking by smoking a cigarette. And it was interesting, too, to hear the various pronunciations of " ego." Personally, I was much relieved when one American psychologist so far descended from the heights as to talk about dropping banana skins, and when Lord Addison confessed to wanting 8 hours sleep in every 24.

* * *

It was rather fun, when I first qualified 20-odd years ago, having 13 letters after my name ; but I did not take the L.M.S.S.A. and the Conjoint to impress the uninitiated. In our hospital the main house-appointments ran in succession—" clinical," A.H.S., O.P.O., and H.P. or H.S.—so once you got the first one you were almost certain to get them all. You could apply for clinical before you qualified, but this was risky, because if you did not pass your remaining exams during the 3 months the job lasted you could not apply for A.H.S. and so you dropped out of the series. Being an optimist I applied for clinical when I still had one part of the Conjoint to pass, and I then proceeded to fail in it. This seemed a disaster of the first magnitude ; my contemporaries would go on but I must return to the status of student.

I spent the next weekend pitying myself, and on the Monday morning paid little attention to the wisdom of my chief on his round. At noon I had a brain-wave. I asked to be excused and shot round to the medical-school office. How about the " L.S.A." I asked : when could one take that ? The secretary told me there was a final exam. starting that very day, so I asked where the Apothecaries lived, jumped into the little Morris I kept in the hospital quad, and by 12.30 I was at their office. The exam. did not start until 2 P.M. But when I asked to take it they were politely firm : candidates must give at least 2 weeks' notice ; they must produce evidence of having attended a long list of courses and of having passed a long list of preliminary examinations ; they must pay 25 guineas—obviously I could not take the examination. In any case the secretary, who alone could admit candidates, would not be back from his weekend until after the paper had started. I said I would come back at 2 o'clock, though they told me it was useless.

I dashed back to the hospital in the old Morris and spent the lunch hour in collecting certificates. None, I swear, was actually forged, though one or two would not have borne very close inquiry. I also borrowed the 25 guineas, some of it in 5-shilling contributions from generous but penurious friends. I got back to Apothecaries' Hall at 1.55 to find that the secretary—bless him !—had returned sooner than expected. He heard my tale ; being young, I was very nearly in tears over it. He was sorry, but it was impossible, I must present myself next time. He went off to give out the papers, leaving me sitting sadly in his office. The clock ticked round, and at 2.15 I got up to go. Then I thought I would stay a bit longer, and at 2.30, when I had just decided it was no good, in came the secretary, with a broad grin, to say that the examiners had considered my case and were making an exception in my favour. He led me in, and I sat down dazedly to do the paper. I did not know on what subject it would be, and I did not care. I did not worry even when there was a clap of thunder and a terrific downpour and I remembered that my poor Morris was still outside with the hood down. At last I came out, to be met by a policeman who took my name and address for lea my car unattended in Queen Victoria Street. I told I had been taking an exam. unexpectedly, but I d think he believed me.

That was not quite the last hurdle, for the results were due on the very evening when the committee met to appoint the new house-officers. I had a friend in committee who promised to stay behind to take application if the result was favourable and was out time. It was a near thing—twice over, in fact—for I just passed in forensic medicine, and the verdict announced with ten minutes to spare.

* * *

The six of us reached the river, after our long dr at about 11 o'clock in the morning, when the W Indian sun was getting fierce. We had been held up bit by meeting the District Agricultural Supervisor mule had strayed off while he was having a dip. Admiral and Lady F—always, despite their age interested in everything and everybody—had a chat with him and asked a lot of questions about his work. He chief worry, apparently, was that the negroes wouldn't bother to cultivate the peasant smallholdings t the government of the island was offering them. When we got to the water, sweating after carrying our gear four hundred yards, we were glad to immerse ourselves (it was too shallow to swim) in the largest pools between the rocks. The Admiral wore his Edwardian swimming costume, but his wife decided only to paddle, as the water was chilly.

Afterwards we dressed and had our picnic lunch in the shade of a bamboo clump on the river bank. We were just polishing off the tinned peaches and lighting cigarettes when a troop of young negroes appeared, holding a net strung out across the river and wading up-stream towards us. They were shouting to one another, waving brown arms and cutlasses, with which they every now and then beat the water or burrowed excitedly under rocks. As they came closer, we saw that one of them carried a clump of fish strung together—mullet, lanky crayfish all brown and spiny, and flatfish with the disc-like suckers with which they cling to the rocks. The youths were marvellous physical specimens, wearing only shorts, with enormous shoulders and pectoral muscles, and as they came crowding round us to display their catch their amiable grins showed wonderful sets of teeth. One lad who had been naked had modestly wrapped a friend's shirt round his waist before approaching. We admired the fish and gave them some cigarettes and the remains of our food, which vanished like magic.

" What a wonderful life," said the Admiral, as they went on up the river, " what a really *wonderful* life! To have this sunshine, all the food they want on the trees and in the river, and friends to go out fishing with on a Sunday morning. No wonder they won't work—damned if I would either."

* * *

Being confined to bed in one of our more famous hospitals I have been reading one of those stories by a " famous surgeon." This has prompted me to write a few words about my own medical career which I intend shortly to publish under the title of *The Peeling Knife* or *They Come by Arrangement with the Publishers.*

I was born of poor but proud and intelligent parents in Westphalia. At the age of twelve I obtained a pos at the University of Presbonitz as a scalpel-sharpener and this gave me my first introduction to that enchanted garden which was to make me one of the foremo eons in Europe. I utilised my position to sneak to the dissecting-room every night and occupy elf with the grisly task of dissection in the dark, of course, I could not employ any light. This, might say, was difficult. but fortunately I have ys had an extraordinary sense of smell which not enabled me to dissect in the dark but was to prove useful in diagnosis in the glorious career which equently opened up for me. My only book was py of Zoroan's *Anatomy*, written in Latin, and the of first learning this language and then studying tomy was, at the tender age of twelve, a grim one. ever, with the image of Hippocrates constantly re my eyes, I was inspired to lay the foundation of t I may call, with all due modesty, a splendid and inguished career. Besides my studies and my work scalpel-sharpener, I was also engaged in running nds for a local eel-seller, and as you can imagine day was full. For three years I had no sleep at all. abit which has stood me in good stead in many a vigil by the bedside of a patient when engaged in desperate struggle against ensuing death.

t the age of twenty, I qualified M.D. at the University Presbonitz, the youngest doctor in Westphalia. what vistas were opened up of service to humanity, rim struggles with man's mortal enemies, with myself ast a combatant. How proud my old parents were, ecially as after three years of work as a house-surgeon as appointed fifth assistant to the great Professor ben and was able to send them a cheque for two lion tonschkas (about 7*s.* 6*d.* in English money).

et me tell you about my first notable case.

he patient was a poor Westphalian peasant with a touching tic simplicity. By studying him with great care I was e to gain his confidence, a step which, as I always tell my nger colleagues, is essential in the successful management of any ailment, however trivial. This peasant, I'll call him Bauer, told me the whole story of his life, his work on the farm, and the careers of his seven children: and although I was forced to spend many weary hours at his bedside taking his "history," as it is called, I discovered something which even the great Professor Gorben had missed. Picture the scene; a large hospital ward filled with professors, lecturers, house-surgeons, general practitioners, and students, with Professor Gorben, "The Prof," as we affectionately called him, standing like a veritable Aesculapius among them. The Prof made a detailed examination of Bauer which took him 3½ hours and was interspersed with much magnificent teaching. Finally he drew himself up and said, "Gentlemen, I will operate tomorrow." A deathly hush fell on the assembly, for all of them knew the seriousness of this operation, of which Gorben was the foremost exponent in world. With my heart fluttering in my mouth but with goal of scientific honesty before my eyes, I said, "But ofessor Gorben, ulcerative gingivitis has set in." I will t dwell on the complex discussion which followed, in which e Prof put some searching questions to me. Suffice it to y that two years later I received a hard-baked scone from uer, baked by Mrs. Bauer, on which was engraved, "To e Man who Saved my Life." Ten years later Bauer was pointed mayor of Presbonitz.

Notes and News

THE PENSIONER IN HOSPITAL

UNDER the National Insurance (Overlapping Benefits) ulations a patient who has been eight weeks in hospital l find that his sickness benefit or pension is cut by ten llings a week, and that after a year a further reduction l be made. But in a letter to the *Times* this week (Aug. 24) correspondent suggests that a pensioner should not be alised for sickness and asks how he is to meet his rent and tine expenses. The reduction is based of course on the nciple that the pensioner is receiving board and lodging the hospital and his day-to-day expenses should therefore reduced. But the pensioner is probably living on a very all margin and besides the small extra expenses which ays go with a stay in hospital he must probably pay at st a retaining fee if he is to have a home to return to when comes out of hospital. The position of the chronic invalid o has entered an institution is different, but as the *Times* mperately points out in a leading article: "it is not ogether easy to justify any reduction in the benefit of the tient, however long his illness, who still has a home or pendents, and a reduction after only eight weeks in hospital indefensible."

POLIOMYELITIS FIGURES

THE final figure for notifications in the week ended Aug. 21 likely to be 70–75, compared with the level of 35–40 in the st few weeks. A seasonal rise has often occurred at this me of year; but last year the rise began very much earlier in the week ended June 7.

PRESCRIPTIONS FOR N.H.S. PATIENTS

THE Ministry of Health suggests that there is considerable misunderstanding among doctors as to the use of the official prescription form, E.C.10. This may be used only by doctors ho have agreed to give general medical services under the ct, and only for patients who are on their lists or have been ccepted as temporary residents. A separate form must be sed for each member of the family. Only medicines, or he appliances and reagents named in the third schedule to he National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948, can be ordered on rm E.C.10; it may not be used for private patients, for rdering foods and food-like preparations or appliances ot in the prescribed list, or for obtaining stocks of drugs appliances required by the doctor in his practice, which ould be ordered from a wholesaler or local chemist in the ual manner.

PIONEERS OF PURE FOOD

FOOD adulteration was a tempting sport for the middleman rough the ages, until legislation came to check him and otect the consumer. Mr. F. LE GROS CLARK has lately ared evidences of the practice from the 14th century and viewed the stages of reform.[1]

Millers and bakers, he says, were particularly knavish, lding mouldy flour, bean-meal, alum, chalk, and whatnot their flour—for which, if they were detected, they might e fined and put in the pillory with the offending loaves ng about their necks. Pepper and spices, ginger, cloves, nd saffron, all inspired the merchants to spin out quantity conceal age. Tea and coffee were sophisticated almost as on as they began to be imported, which roused the 8th-century pamphleteers. The bakers, too, were still in ad odour, and were plagued with broadsheets and lampoons own to the end of the Napoleonic wars. But a more ormidable assault was being prepared. In 1820, Frederick ccum, a competent chemist, published a book on adulteration hich dealt with alum in flour, the poisonous colouring of onfectionery, and the adulteration of beer: and this reliable ork ran through four editions. His charges were repeated 1848 by John Mitchell, and were taken up by Thomas akley, editor and founder of THE LANCET, and at that me a member of Parliament of many years' standing. In 851 Wakley set up a LANCET commission to analyse common ods and publish results, and in this task he was helped y Dr. Arthur Hassall and by Henry Letheby, lecturer in emistry at the London Hospital. For four years Wakley ublished articles on the commission's findings, and in 1855 athered them into a book *Food and its Adulteration*. Hassall found half the milk samples diluted with water, every sample of sugar mixed with lime, lead, or sawdust, every sample of mustard with flour and turmeric, and every loaf sophisticated with alum. Three-quarters of the cocoa samples contained added starch, and tea had been treated with indigo, black lead, and mica. Used leaves had been sold with a mixture of sloe and bay leaves, doctored with iron sulphate and gum, as finely blended tea.

The result of these exposures was a steady growth of protective legislation, culminating in the consolidating Act of 1938, and the Defence (Sale of Food) Regulations of 1943.

JUNK PLAYGROUNDS

OLD Kaspar's grandchildren, with a battlefield for playground, sported contentedly with a skull, and probably used bones for building houses. Children have long recognised the constructive possibilities of junk of all kinds, and greatly relish woodyards, sawpits, quarries, brickyards, and bombed sites—a fact which those who design asphalted municipal playgrounds, set orderly with swings, have quite failed to appreciate. The idea of the recognised, official, and well-equipped junk playground comes from Denmark, an account of one, originally published in *Picture Post*, has lately been reprinted in *Out of School*,[1] the second report of the Central Advisory Council for Education. This Danish playground is provided with stone, earth, bricks, wood, iron, clay, water, planks, empty petrol-cans, wheelbarrows, and derelict motor-cars—an exceedingly popular type of equipment. The children are taught the use of tools, and then build what they fancy. The playground leader examines every finished house, tower, or cave, to make sure it is safe before the children play in it. They make their own furniture, their forks and spoons, their kitchen utensils, and decorations. Some of the older children have built a climbing apparatus 35 ft. high and a working windmill. The leader in this playground is a nursery-school teacher who was formerly a seaman; his task is to help the children to understand the problems their projects entail, and to put them in the way of learning how to do it: they do the rest. During the three years the playground has been running there has been no serious accident; the children find out for themselves how far they can go with safety.

The idea of junk playgrounds is warmly supported by the National Under Fourteens' Council. In a well-illustrated pamphlet[2] they suggest what might be done to develop them here. The bombed site is, of course, one of the many places where such playgrounds could be set up; and they are particularly needed in towns where children often have no playgrounds near their homes. Naturally it is necessary to consider possible sources of danger, such as unsafe walls, service mains, and basements. Where preliminary clearing must be done, the children who are to use the site should help; and plenty of tools, scrap materials, and gardening equipment are wanted. In a foreword to the pamphlet Lady Allen of Hurtwood points out that much delinquency can be traced to boredom. Here is a playground suited to the active and inventive child. Those who plan municipal playgrounds, she says, "should consider the needs of the children before they put set-squares to paper, or spread relentless asphalt over the earth."

Those who are interested in the N.U.F.C. project, or who would care to contribute to it in cash or kind, are asked to write to the organising secretary, National Under Fourteens' Council, Mary Ward Settlement, London, W.C.1.

THE PARTIALLY SEEING CHILD

WHILE special arrangements have long existed for the education of blind children, no such provision was made for the partially sighted until the early years of this century. Children who could not read ordinary school books were educated as though they had no vision at all until James Kerr, medical director of the London School Board, invited Mr. Bishop Harman to investigate the position. He found that many of the children in the blind schools had been placed there because of high myopia, and he recommended that these children should be removed and given special education better suited to their needs. And so, in 1908, in a little one-story building in Camberwell attached to a general school, began the first class in the world devoted entirely to the education of partially sighted children. Since those days the views of ophthalmologists on the care of immediately ensued, and a slamming of doors indicated the exit of the valuable material. The hunt led to the nearby playground where after some coaxing the two younger members were persuaded to hold their hands warily through the railings. Once again dysplastic thumb-nails indicated that the chase must be continued, though fortunately the early return of the remaining daughters to the house saved me from having to utilise the swings and other apparatus to obtain their confidence. Finger-nails were then minutely studied with a hand lens, knees inspected, and buttocks palpated; and all five small daughters, together with their married sister and her newborn baby, turned out to be built on a similar pattern.

The atmosphere of hostility, aggravated by my use of the term "abnormal," which had been wrongly interpreted as referring to their mental equipment, now changed to one of stark incredulity, as if they were standing before a benign lunatic. How could I explain to them about genes, mutation, and the chromosomes? It was hopeless. However, by a stroke of luck I mentioned that a report on them might appear in print. Instantly my quest assumed a new dignity, and when I left the family were feeling immensely important and certain of impending fame.

* * *

Letter to a Nephew

MY DEAR CHARLES,

I am flattered that you should ask for my advice before finally deciding to take up medicine, but I must warn you that no easy straightforward answer will be forthcoming. Whether you are likely to do well in medicine, and if so whether I recommend general practice—these things depend entirely on what you are.

Let me begin with a few questions. In the first place, why medicine at all? Have you chosen it in compliance with the family tradition, or do you feel the vocational urge, or are you after a worth-while job which will enable you to realise such ambitions for power, popularity, and the like as you may have? I mention three usual reasons for taking up medicine, but with your robust personality perhaps we can eliminate the first two. In my opinion, for what it is worth, pressure from without is a third-rate reason for becoming a doctor, though you will win the approval of your immediate environment if you profess to be swayed by it. As for the vocational urge, to tell you the truth I think it is just a little unhealthy; it is not characteristic of a person who will withstand strain and carry responsibility with ease. At any rate, rest assured that I regard a desire to secure a decent livelihood, with or without other ambitions, as a very good starting-point; and you will find that most men who do well in general practice set out with some such aim in view. This stamps them as life-sized human beings with understandable values and motives, and it allows them to get on with their work unhampered by tensions such as fixed goals and high ideals engender. The less you court disillusionment in advance, the better.

If you have the ability to qualify—and it has to be fairly good ability these days—you will be confronted by your next choice. There is no need to ponder the problem unduly at this stage, for you will find that your own personality will solve it for you; if you are restless and ambitious enough, you will disregard circumstances and strike out on your own, probably becoming a specialist or scientist. If your urge meets with an odd chance you may find yourself in a local-government post of some kind, and if nothing urges you away from the path of least resistance you will probably try general practice. Do not make the mistake of imagining that anyone can succeed in general practice. It is a test of quality and endurance not met in the specialised branches of the profession.

You will be successful if you are loved and trusted, and you will be loved and trusted if no character fault stands in your way. So far as I am aware you have none, but if you had, general practice would soon bring it out and you would have to make the best of it as an indifferent doctor. There are a number of these, and only exceptional piece of luck will enable them to get out general practice and possibly make good elsewhere. M of them will remain minor or major misfits, and the advice one can give them is that they should cut their l and stick to jobs well within their capacity. Locums and assistantships offer a very reasonable living with imposing the strain which will tax a less-than-heal personality to breaking-point. Within such limits indifferent doctor can still be an adequate doctor.

However, let us suppose that you will make a su of it. You will want to know something about a succ G.P.'s life. Have you ever wondered, Charles, what is that sustains the good family doctor, and how contrives to look flourishing and serene on hurried m interrupted nights, and a permanent load of respo bility? It is something of a miracle surely, for you m remember that he deliberately clings to a calling w makes the most extraordinary demands on him: he to make instant and serious decisions when woken in the middle of the night; he cannot afford to feel ill or too tired to see the patient who needs him, ticularly when the patient is seriously ill; and yet will be his breezy and affable self in surgery the next morning no matter how he spent the night. Is he superman, or an oddity intent on amassing money I hope you are dismissing these wild conjectures.

Try asking yourself why you send for one particular man when you are anxious and distressed. From him you expect something more than medical skill; and the greater your predicament, the more you depend on the support and reassurance of one personality rather than any other. Why? If you examine the question realistically you will find that you have placed your confidence not in a saint or a freak, but in a wise, kindly, reliable human being. His humanity will be obvious to you from what he has to give, but that is only one half of him; you must now ask yourself what he takes, for you cannot give him human stature by just assuming that he is "made that way," that he will be quite happy as long as he can go on giving. So far from being negligible, his takings are the real secret of the driving-force which sustains him; but what are they? Well, it rather satisfactory to have people depend on you, h upon your every word, regard you as a friend, and p their confidence in you. You like dealing with them, you give affection in return, you move and work in a friendly tension-free atmosphere. In short, it is the much maligned doctor-patient relationship, which I have tried hard to avoid mentioning since you have heard so much about it already and are very pardonably sceptical of it. Nevertheless, it is a relationship emotionally so rich and satisfying that it will keep your doctor vital and happy and it is of an order which constitutes an end in itself. It has nothing whatever to do with medical ethics, finance, or methods of administration; if you like, you can call it love, though you will need to interpret the word rather carefully. Perhaps it will help if you imagine yourself as a doctor in relation to a household which you can transform by your mere presence in the sick room; what does such a household give you? It has placed implicit trust in you in preference to anyone else; it gives you affection and respect, and it invests you with enormous power—power which overwhelms you at first and makes you feel rather humble. You can change the tenor of their lives with it, not necessarily by curing the sick, but by infusing your strength and courage into them so that they will accept the inevitable with something like triumph instead of helpless dejection. I ask you, could any effort of yours be called unrewarded with all these gifts spread before you, and could you name any reward which you would rather have? Well, Charles, shall we say it's worth it?

YOUR AFFECTIONATE UNCLE.

ACCIDENTAL INTRA-ARTERIAL INJECTION OF DRUGS

SOL. M. COHEN
M.A. Cape Town, F.R.C.S.
SULTANT SURGEON, GRAVESEND AND NORTH KENT
HOSPITAL, GRAVESEND; FORMERLY SURGEON,
SOUTHERN HOSPITAL, DARTFORD, KENT

943, while I was working on traumatic arterial
my attention was drawn by Prof. R. R.
osh and Colonel Hedley Atkins to several tragedies
ng the accidental intra-arterial injection of
thiopentone ('Pentothal Sodium.') The cases
of interest not only from the point of view of
ed for a rationale for the management of such
but also because they suggested a means for
ing traumatic arterial spasm experimentally.

eview of the cases has shown that, though spasm
ajor vessel does not usually follow such injection,
velopment of extensive thrombosis (often late),
arteriolar spasm, and severe œdema presented
ms commonly met with in arterial injuries and
e. This paper is concerned chiefly with the detailed
of eight unpublished thiopentone cases and includes
analysis of four of the published cases in which it has
ossible to obtain pathological material, and further
s of the findings at operation and the treatment.
ted cases of tragedies following intra-arterial
ions of diagnostic and therapeutic media are also
ved.

ish to emphasise first of all, from a close study of the
records and first-hand accounts from the anæs-
sts, that these tragedies in no way reflect on the
thetists' competence and are not necessarily due to
essness or bungling. This accident can happen to
ne. One anæsthetist has had the misfortune to be
nsible for two such tragedies; and in one hospital,
gh the hazard was well recognised, there have been
tragedies and four other cases in which the injection
almost certainly intra-arterial but fortunately with
toward results. The case-records indicate that there
been little groping for the vein, and the injection
ften been particularly easy. Intra-arterial puncture
t followed, as is commonly imagined, by a gush of
l blowing off the syringe piston; those who have
arteriograms know that definite aspiration is often
ired. Nor is the crimson livery of arterial blood
ily discerned in the yellowish solution. Moreover,
anæsthetist usually aspirates, momentarily only,
ere wisp of blood—and this under difficulties, for
is seldom permitted the luxury of a decent light
le giving his injection.

ontrary to what is taught, puncture of the arterial
l is usually painless. I have done numerous arterial
ctures for arteriography under local anæsthesia and,
test this point, have confined the anæsthetic solution
the skin only. The puncture alone is not felt; the
ima appears to be insensitive. Large vessels may be
nlessly tied. Puncture of a vessel is painful only in
case of arteries covered with a network of sensory
ves—e.g., the radial and common femoral. Lewis
42) has shown, in animals, that barium chloride
cted into the arterial lumen is painful only if allowed
reach the distal capillary tree. One finds the same
g in brachial arteriography: when 35% diodone
njected with the arterial circulation arrested by an
ated tourniquet, no pain is felt until 4–5 ml. has been
cted; the patient then complains of a hot burning
n in the hand and fingers, and this continues as long
he tourniquet is kept inflated. Radiography shows
t this small amount is adequate to fill the entire
al arterial tree. The pain is similar to, though not
vell marked as, that following intra-arterial thiopentone; the quantity (4 ml.) represents the minimal amount of 10% thiopentone that has hitherto been reported to be followed by serious effects. It is a pointer to the anæsthetist to inject, as has been recommended (Macintosh and Heyworth 1943), say 2 ml., and pause a few moments for any complaint of pain.

It is strange that complications such as extensive thrombosis should follow injection into the swiftly moving arterial stream; for, if thiopentone was such an irritating corrosive, a far higher incidence of venous thrombosis would be expected, the venous tree, as every surgeon knows, thromboses all too readily on any damage. The explanation for this I do not yet know; but several factors may be responsible: the resistance of the arterial wall due to its relatively abundant muscle and elastic fibres; the temporary arrest of the arterial circulation by the inadequate release of the "venous" tourniquet; and the trapping of the solution in the arterial tree by vigorous flexion of the elbow after the injection.

SIGNIFICANCE OF VENOUS THROMBOSIS

Venous thrombosis, as Adams (1944) points out, is usually delayed; coming on from the fifth to the tenth day, and with a 5% solution there has been an incidence of 10 in 10,000 administrations; with the $2^{1}/_{2}$% solution the complication is rare. In this country, Evans (1939) and Payne (1939) have reported isolated examples; Solomons (1945), using a $2^{1}/_{2}$% solution, reported an incidence of 1 in 700 in acute battle casualties in a tropical area. The question has arisen whether extensive venous thrombosis may not alone lead to limb gangrene, for this is known to have followed the accidental injection of sclerosants into the deep veins of the leg (Erb 1944, Foote 1945, Luke and Miller 1948).

In several of the thiopentone cases the site of vessel puncture could not subsequently be found at operation, and there appears to have been no arterial leakage whatsoever. This is surprising, for anyone who has done arteriography will have observed that the vessel leaks considerably, the adjacent adventitia is usually heavily stained, and, even if the vessel is compressed rapidly after withdrawal of the needle, a hæmatoma bleb invariably forms in the adventitia. However, in some of the recorded tragedies following arteriography the puncture site has likewise not been visible (Leveuf 1938).

Deep venous thrombosis cannot be lightly dismissed as a possible factor responsible for death of the limb or other serious complication, such as Volkmann's contracture. Leriche (1945), Cohen (1946b), and Fontaine and Forster (1946) have commented that when the arterial circulation is poor, or in spasm, the onset of venous thrombosis will seal the fate of the limb; the increased venous pressure raises the intracapillary pressure, bringing the local circulation to a standstill. Venous obstruction alone, it is now believed, may lead to death of muscle from Volkmann's ischæmia; microscopically, the picture differs somewhat from that of the arterial lesion (Griffiths 1940), but the end-result—extensive fibrous-tissue infiltration—is the same (Bowden and Gutmann 1945, Albert and Mitchell 1943). Such deep thrombosis following prolonged blood-transfusion for severe hæmatemesis has been followed by Volkmann's contracture in the transfusing arm (F. R. Kilpatrick, personal communication). After the injection of thiopentone the venous thrombosis may be extensive and involve the deep veins as well by retrograde flow. With intravenous injection at the elbow phlebography shows clearly (fig. 1) that the solution does not merely continue its flow in equable fashion in the punctured vein but also owing to the situation of the vein valves, descends a considerable distance into the forearm and then spills over into the main interlacing venous net. Hewspear (1945) has described in detail a case where extensive myopic children have changed: it is now agreed that a reasonable amount of reading and writing under the best conditions does not cause myopia to advance, and that heredity and feeding are more important influences. But the schools for the partially sighted are doing invaluable work for children whose visual acuity is reduced from other causes, such as cataract and hereditary anomalies, as well as very severe myopia. Children whose vision in the better eye is between 6/18 and 6/60 are suitable for these classes provided their mentality is normal. Since these children are helped by *taking some oral lessons in company* with their normal-sighted colleagues the special schools are usually attached to an ordinary elementary school.

The idea of these schools spread from England to Europe in 1911 and to the U.S.A. in 1913. Mrs. Winifred Hathaway,[1] associate director of the National Association for the Prevention of Blindness in America, has set out the latest methods, which, as one would expect, have achieved a high degree of *ingenuity and mechanisation in the U.S.A.* For instance, the lighting in the class-rooms is controlled by a photo-electric cell which turns on lights automatically whenever foot-candles fall below an indicated level. Much work remains to be done and more classes are needed; thus in the U.S.A. it is estimated that 50,000 partially seeing children still lack opportunity for proper education. Local authorities in Britain who think of starting such classes cannot do better than read Mrs. Hathaway's wise words, for she has something sound to say on all aspects from transport to finance, and from talking books to clay modelling.

Society of Apothecaries of London

At a court of assistants held recently Prof. E. C. Dodds, F.R.S., was re-elected master for a further year, and Mr. Duncan Fitzwilliams and Dr. Frank Howitt were elected wardens. Dr. Reginald Fisher was welcomed to a seat on the court. Nelson Courtney Lendon was clothed by the master with the livery. R. J. Mather was bound apprentice to Sir Cecil Wakeley for four years. The following were admitted to the freedom of the society:

R. F. B. Bennett, P. M. F. Bishop, D. C. Muir, Richard King-Brown, J. W. Brown, J. St. C. Elkington, B. G. B. Lucas, J. B. Stanton, R. St. J. Buxton, Bartholomew Hynes, J. W. McCloy, R. H. W. Britton, George Richards-Smith, A. G. Hucker (by redemption); W. H. D. Fairbank (by servitude); A. C. Townsend (by patrimony).

The following were sworn in as examiners:

Dr. Kenneth Harris (medicine); Mr. A. Wallis Kendall (surgery); Prof. F. Goldby (anatomy); Prof. T. H. Barcroft (physiology); Prof. W. H. Linnell (chemistry).

The following diplomas were granted:

Mastery of Midwifery.—G. H. Hall, R. Hodgkinson, J. I. Miller, G. F. Newbold, C. M. Stacey, M. O. Will.

D.I.H.—J. N. Heales, C. H. Hoskyn, W. A. B. Reynard, D. G. Robinson, S. J. M. Walker, F. Wrigley.

L.M.S.S.A.—O. B. Beardsley, J. A. W. Berryman, A. I. Berwitz, A. C. Bojó, W. Bust, G. Capper, D. Davis, E. R. Ettlinger, K. H. Ghobrial, A. J. Glyn, P. G. Green, A. D. Griffith, N. Kacas, N. B. Kenyon, S. P. Lapage, D. F. Little, R. J. F. Moore, B. Newton, N. Rivers, V. E. S. Rolfe, M. V. Salmon, R. J. H. Snelson, J. S. Swifte, F. R. Walker, W. Winterstein, W. B. Wolstenholme.

St. Thomas's Hospital Dinner

The Old Students' dinner will be held at the Grocers' Hall, Princes Street, London, E.C.2, on Friday, Oct. 1, at 7.30 P.M. Mr. W. G. Howarth will be in the chair.

Boards of Governors of Teaching Hospitals

Recent changes of membership in these boards include the appointment of Sir Drummond Shiels to the board of the Hammersmith, West London, and St. Mark's Hospitals and of Prof. H. V. Dicks to the board of the National Hospitals for Nervous Diseases.

Extra Rations for the Tuberculous

The Ministry of Food announces that patients with active tuberculosis who receive additional allowances of milk, cooking fat, and bacon are now to be also allowed an extra 3 oz. of butter/margarine and an extra 3 eggs a week. Those eligible should take or send their ration books to their local food office to obtain the necessary permit. Sanatoria and hospitals can obtain the extra allowances for each of their patients with active tuberculosis.

Central Mediterranean Force Surgeons and thetists Dinner

The annual dinner of the surgeons and anæsthetists served in the Central Mediterranean Force will be held Claridge's, Brook Street, London, W.1, on Sept. 23 at 7.30 Tickets may be had from the secretary, 4, University Squ Belfast.

Medical Films

In connexion with the international scientific film co which is being held in London from Oct. 8 to 12 the Scien Film Association are arranging three morning sessions viewing and discussing medical films. Two meetings be held at 1, Wimpole Street, W.1, on the 8th with Sir Ke Goadby in the chair, and on the 12th with Dr. E. Go Rawlinson in the chair. On the 9th, at 1, Lambeth Street, S.E., Dr. Ronald MacKeith will preside over a de stration of methods of still and cine-photomicrography. organisers invite owners of medical and biological films w they would be willing to lend to write to the org specialist medical sessions of the congress, 34, Soho Sq W.1. Applications for admission should be sent to the address.

Surgeons' Gowns and Coat Overalls

Private practitioners who undertake operations, obste venereal disease treatment, or autopsies, can receive co equivalent certificates for gowns. This now also applies those who do their own dispensing, and to pathologists. Board of Trade have agreed that industrial coat overalls be bought instead of surgeons' gowns. Practitioners ent or returning to practice can get certificates to buy up gowns or coat overalls. Those already in practice may an annual replacement of 3 gowns or coat overalls. Doctor England and Wales can apply for certificates to the Mini of Health, Whitehall, London, S.W.1; in Scotland, to Department of Health for Scotland, St. Andrew's Hou Edinburgh; and in Northern Ireland, to the British Med Association, B.M.A. House, Tavistock Square, London, W.

Appointments

DAVIDSON, WILLIAM, M.B. Leeds, D.M.R.D.: asst. radiologist, R Halifax Infirmary.

KENDALL, A. C., M.B. Birm., M.R.C.P.: registrar (B1), pædi department, Radcliffe Infirmary, Oxford.

* LOVETT, W. C. D., M.D. Lond., B.SC. Wales, D.P.H.: M.O. (h duties) British Somaliland.

SWAN, J. F., M.D. Glasg., D.OBST.R.C.O.G., D.P.H.: M.O.H. school M.O., Bootle.

TELLING, MAXWELL, M.A., D.M. Oxfd: asst. physician, Ge Infirmary, Leeds.

WALKER, J. H. C., B.A., M.B. Dubl., D.P.H.: bacteriologist, P Health Laboratory Service.

YOUNG, R. V., M.A., B.M. Oxfd: clinical pathologist, Horton Ge Hospital, Banbury.

Royal Northern Hospital, London:

JEWESBURY, E. C. O., M.A., D.M. Oxfd, M.R.C.P., D.P.M.: phys neurological department.

NEUSTATTER, W. L., M.D., B.SC. Lond., M.R.C.P.: phys psychiatric department.

SHARP, B. B., M.D. Lond., M.R.C.P., D.P.M.: physician, psych department.

* Amended notice.

Births, Marriages, and Deaths

BIRTHS

GREWAR.—On Aug. 14, at Dundee, to Dr. Joyce Grewar, wi Dr. David Grewar—a daughter.

ESSEX-CATER.—On Aug. 11, in London, the wife of Dr. An Essex-Cater—a son.

KEMP.—On Aug. 19, in London, the wife of Dr. T. A. Ke a daughter.

MARRIAGES

BOYLE—SMITH.—On Aug. 19, at Middlesbrough, Philip Te Boyle, M.B., to Dorothy Smith.

GILLIS—GREAVES.—On Aug. 12, in London, Leon Gillis, M. F.R.C.S., to Rachel Greaves.

DEATHS

HIGGS.—On Aug. 12, at St. Leonards-on-Sea, Walter Alf Higgs, M.R.C.S.

JAMIESON.—*On Aug. 20, in Dublin, John Kay Jamieson,* M.B. I

LOWE.—On Aug. 18, Percy Roycroft Lowe, O.B.E., B.A., M.B. Ca aged 78.

PARMITER.—On Aug. 19, at Wimborne, Bernard Rayne Parm M.B. Lond.

PERCEVAL.—On Aug. 19, at Bournemouth, John Lancel Perceval, M.R.C.S., aged 61.

---

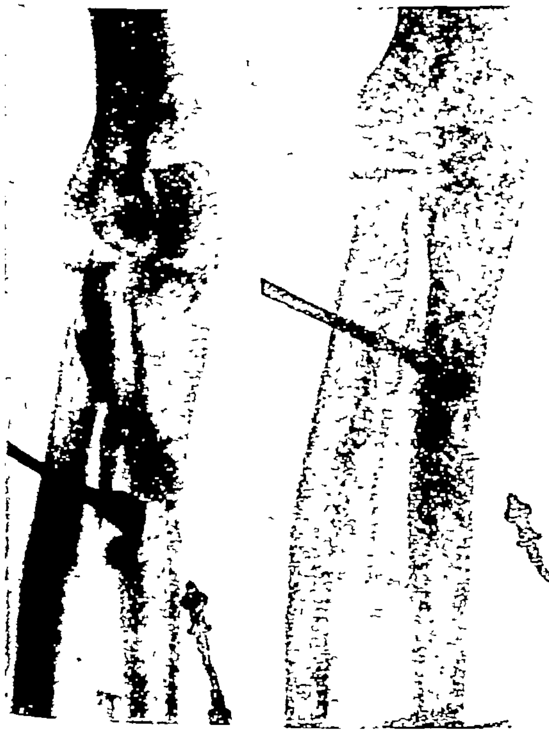
[1] Hathaway, W. Education and Health of the Partially Seeing Child. London: Oxford University Press. 1948. Pp. 216. 14s.

as reduced to diastolic pressure. The coloured fluid not rise more than 3–4 cm.; but, if the flow was cut he coloured fluid could be made to ascend 12 cm.

is observation confirmed my impression that, to t the thiopentone high into the arm, there had been ial or complete obliteration of the pulse during the tion—due to arm or neck posture, or to the fact that "venous" tourniquet, rubber, or assistant's comsion had been inadequately released. A very transient rial spasm which may give the solution an opporty to ascend and be held can also follow too usiastic compression of the arm by the assistant. t this may have happened is shown by the report ne of the cases, that blistering subsequently developed he site where the nurse had maintained pressure on arm.

MPRESSION OF SUBCLAVIAN AND AXILLARY ARTERIES

is important for the anæsthetist to be aware of the hanical factors which may temporarily obliterate reduce the brachial and distal pulses. In a high entage of normal persons bracing of the shoulders lead to compression of the subclavian artery by the ricle against the first rib and loss of distal pulse; andbag between the shoulders may do it. Strong nward traction of the elbow, such as firm tucking in the hands under the buttocks, may obliterate the se, and gangrene of the hand is known to have owed this. A forceful deep inspiration will in some sons lead to the transient disappearance of the pulse; mechanism is not clearly understood, but arrest of the se may be due to ascent of the first rib compressing rib against the clavicle, or to the scissors-like gripping the subclavian artery by the scaleni muscles. Placing e arm above the forehead may obliterate the pulse; right (1945) found that in over 80% of 150 young adults e pulse was obliterated when the arm was elevated full abduction; the axillary artery is believed to be compressed or angulated over the root of the coracoid process or over the tendinous insertion of the pectoralis minor muscle. Cervical ribs have always to be borne in mind; the pulse is readily obliterated in such cases by posture. The anæsthetist must also remember that in some persons rotation of the head, or hyperextension of the neck, will lead to compression of the subclavian artery and loss of the distal pulse. In one of the thiopentone tragedies the injection of 4 ml. of a 10% solution was followed by extensive arterial thrombosis up to the axilla—the patient was in the Trendelenburg position at the time of the injection, and the anæsthetist rightly presumed at first that the posture rather than the injection was responsible for the absence of the radial pulse and for the effects in the hand. If thiopentone is injected into a nonpulsating artery, it will not only ascend to a high level but also will maintain its action undiluted. Hasler (1948) discusses some of the complications following such faulty posture in anæsthesia.



ig. 2—Arteriograms: (a) full-force retrograde injection, showing height to which fluid ascended and enormous distension of arterial lument; (b) slow injection, showing filling of arterial tree.

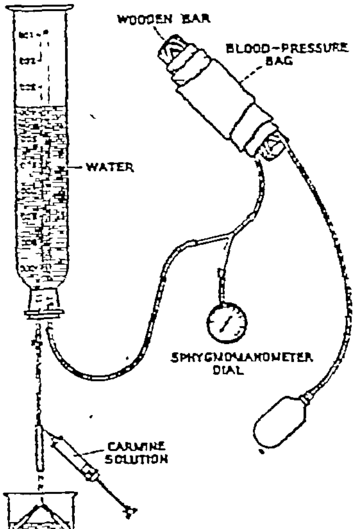


Fig. 3—Apparatus to mimic fluid flowing at arterial pressure and giving a flow of 30 ml. per min. in forearm: needle is introduced through rubber junction, carmine is injected with full force upwards through glass tube, and height of ascent of fluid is measured.

Pulse

The pulse has not always been closely observed in the affected limb; it may certainly remain full, and in two of the cases blood-pressure readings on palpation were the same in both radial arteries. The radial pulse has been found full for an hour and then disappeared; in one case the pulse was absent for an hour and returned only to disappear later. In three cases the full pulse gave a feeling of optimism, but pulsatian ceased some days later with alarming suddenness; in one, a child, it disappeared on the eighth day; in the second case the radial pulse disappeared on the tenth day, and section showed the vessel lumen lined with fibrin adherent to the intima but still patent; in the third case the radial pulse suddenly disappeared on the sixteenth day, and operation showed the brachial tree plugged with clot. The conclusion to be drawn is that the presence of a pulse does not exclude the possibility of severe damage to the intima and later precipitate thrombosis.

CLINICAL FEATURES

Pain

Intra-arterial thiopentone injection causes severe pain, coming on when about 2 ml. has been injected. The pain is agonising, and patients have described it as "like boiling water being poured over my hand," "a feeling as if my hand was on fire," "the hand felt like a flaming branch." On several occasions the complaint of pain during injection was regarded as due to the "patient's nervousness"; in one case the possibility of thiopentone being responsible for the postoperative pain was so completely overlooked that a neurologist's opinion was invited. He observed the thrombosed radial artery and indicated the cause. "Nervousness" on the part of the patient cannot be entirely dismissed as a contributory cause to the development of the more severe sequelæ.

deep venous thrombosis followed the injection of thiopentone, and attributed this as in part due to the placing of the elbow in acute flexion (the hand being tucked behind the head) after the injection. I have seen an injection of thiopentone followed by an enormous œdematous forearm which took over nine months to subside. Such cases are rarely reported.

Anæsthetists need to be aware of the dangers of venous thrombosis; for, should intra-arterial injection be suspected, it would be unwise to risk thrombosing the veins in that arm, and any further thiopentone should be injected into the opposite arm. The present practice, too, of violently flexing the elbow after intravenous puncture can have no physiological sanction; local pressure and elevation of the limb are obviously what is needed. Moreover, such acute flexion of the elbow will obliterate the forearm pulses in most normal persons and may be responsible for the trapping and long-sustained action of any intra-arterial thiopentone.

INCIDENCE OF INTRA-ARTERIAL INJECTION OF THIOPENTONE

Intra-arterial injection, fortunately, has been a rare accident; within the last five years, after making full inquiries from leading anæsthetists and surgeons in this country, I have been able to gather only eight unreported cases. Lundy (1942) reports 3 intra-arterial punctures in 25,000 cases. In the B.L.A. campaign there was only one case (Porritt et al. 1945), and I am indebted to Brigadier A. E. Porritt, C.B.E., for the following report from Lieut.-Colonel J. H. Rink (anæsthetics adviser, 21 Army Group):

> "I only came across one case of intra-arterial injection of pentothal during the existence of 21 Army Group. The injection was undoubtedly made in the artery, and 3 ml. was given before it was realised; the anæsthesia was then continued with gas and oxygen. The patient complained of the typical intense pain along the course of the radial artery and in his hand, but he subsequently suffered no ill effects. I saw him next day, when he was normal in all respects, though no palliative injection of procaine was made, as some times recommended."

In the B.L.A. campaign, out of 181,000 casualties 55,000 required some form of front-line surgery; it may reasonably be presumed that most of these had thiopentone. One in 55,000 is probably a fair figure of the incidence of such major thiopentone tragedies in this country.

Particularly tragic is the fact that the thiopentone accidents have happened in the course of some relatively minor operation—e.g., for tonsils, ischiorectal abscess, hammer toe, uterine dilatation and curettage, knee cartilage, and, in one particularly pathetic case, colostomy; the helpless pitiful state of the latter patient with one arm can well be imagined. The 10% solution has been responsible usually for the serious effects, but in several of the tragedies the 5% solution was used. Several anæsthetists declare that they believe that they have accidentally injected the 5% solution into an artery without untoward effects; a well-marked limb flush has been the only subsequent complication. I have been unable to trace any case that has followed the use of hexobarbitone ('Evipan').

HEIGHT OF ASCENT OF RETROGRADE ARTERIAL INJECTION

A 35% solution of diodone was injected in retrograde fashion into the flowing arterial stream during an operation on the ulnar artery for arteriovenous aneurysm. The fluid was injected with full force through a two-way tap by an assistant after I had punctured the artery. Fig. 2 shows to what an enormous extent the artery was forcibly distended, and that the injected solution ascended into the brachial tree and was then redistributed. The exposure lasted $2^1/_2$ sec., the distal tree did not fill, and the solution was held. This explains why a retrograde arterial injection of thiopentone may have a some-

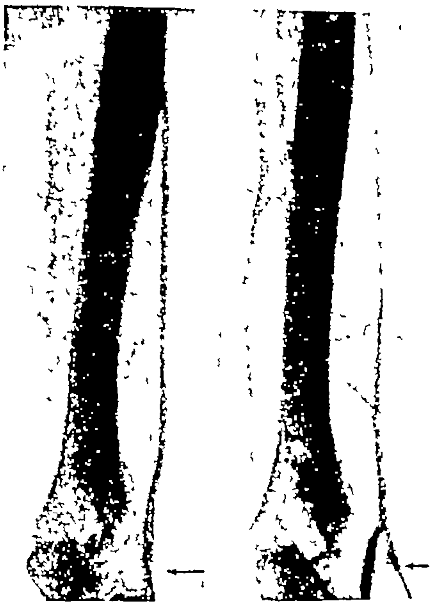

Fig. 1—Phlebograms: injection at elbow; arrows indicate points; note retrograde flow into forearm and spill or connecting veins.

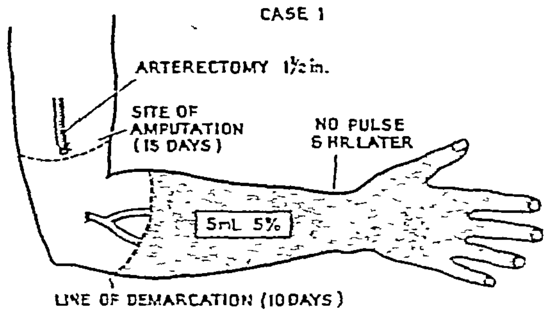
what long-continued action. Despite this violent stre of the artery spasm of the major vessel was not tained; when, with the needle kept in place, the inj was repeated in the time that it takes to change a the major vessel was now of normal size and the arterial tree was already filling. This injection lasted $2^1/_2$ sec. but was slow and gentle. Slow inj may explain why some of the intra-arterial thiope injections were not followed by serious lesions; ready distal escape of the solution spared the vessel and allowed the thiopentone to become di

Arteriography also demonstrated that despite force injection the solution ascended against the fl arterial stream not much more than 6–7 cm.; gentler injection 3–4 cm. only (fig. 2). In the thiope cases operation has shown that the vessel may be with thrombus extending as high as 5 in. (12 5 above the elbow, and in one case up to the axilla. common experience that, with any trauma, a thrombosis does not ascend higher than the n proximal major collateral branch. This suggeste the high ascent of the thiopentone could only have possible if the arterial circulation had been either pletely or partially occluded during the injection. were two possible causes for this: (1) inadequate r of the "venous" tourniquet; and (2) mech obliteration by the patient of the subclavian or ax arteries by the clavicle or other local mechanism, to the position of the limb on the operating-table.

To investigate this, apparatus was designed to r fluid flowing at arterial pressure (fig. 3) conforming the blood-flow in the brachial artery under n conditions. Fluid was arranged to flow at 30–4 per min., with air-pressure above the fluid at n blood-pressure level. This flow was decided on in of the plethysmograph studies of Barcroft and Ed (1946) and Goetz (1946), who have shown that the b flow in the forearm under resting conditions is 3– per min. per 100 c.cm. of forearm tissue. Since average forearm volume is about 1000 c.cm., this m a flow of 30–40 ml. per min. through the brachial a This figure might well be doubled when the distal are warmed (J. McMichael, personal communicat A coloured solution was then injected with a 10 syringe into the flowing stream. A similar injection also tried when the air-pressure head above the



4—Stippled areas in all figures indicate gangrene, unless otherwise indicated.

ompression by incision must be considered. The ticular indication is a centripetal spread of the anæs- sia. Such fascial decompression was done in one of e cases with good result.

A further observation was that the fingers developing ngrene did not develop œdema; the fingers that covered did. The absence of œdema indicates that the rculation in these fingers must have been completely rested, that the major digital vessels were thrombosed. he fingers that recovered can have had spasm of the gital vessels only.

The march of events in the fingers after intra-arterial jection of thiopentone so closely mimics that of the "high-altitude frostbite" cases that were seen during he war that we turn to the beautiful studies by Davis t al. (1943) for comparative information about the athology. They showed by capillary microscopy that here was either thrombosis or intense spasm in the distal rteriolar-capillary loops; such spasm might be main- ained for twenty-four hours at least. When thrombosis ad taken place in these digital vessels, no therapy was ny good; and that applies to the thiopentone cases. An nteresting observation, too, was that some of the "high-altitude frostbite" cases subsequently developed "Raynaud's phenomenon" sensitivity to cold. One f the thiopentone cases that I examined several years fter the injection had a similar complaint; a fact which may be of some medicolegal importance.

Loss of Consciousness

After intra-arterial injection of thiopentone, loss of onsciousness was usually delayed, but apparently not more than 45–50 sec.; recovery of consciousness was rapid in several cases. With 3 ml. (5 or 10%) injected within 8 sec. unconsciousness usually followed within 20 sec. (Hunter 1947). Since total gangrene followed the intra-arterial injection of 4 ml. of 10% *thiopentone* and the patient lost consciousness, most of the solution must have passed through the arterial tree and could have been but momentarily trapped. The irritant action of thiopentone must therefore be immediate and powerful. This fact indicates that the intra-arterial injection of local antidotes—even if available—would be too late.

CASE-RECORDS

Case 1.—A soldier underwent excision of knee cartilage under low spinal anæsthesia, coöperating well. When tourniquet was applied he became restless and complained bitterly of pain. Skin was anæsthetic to forceps clipping, and operation continued. Patient, however, became agitated and apprehensive, tossing his head from side to side.

Injection of 5% thiopentone into right basilic vein at level of antecubital fossa was begun. Immediate complaint of pain at injection site. Since repeated aspiration did not show arterial blood, pain was attributed to patient's extreme apprehension. After 5 ml. he suddenly jerked his arm, and a large hæmatoma formed. Needle was removed, and cyclopropane anæsthesia continued.

Three hours later patient complained of considerable pain in antecubital [illegible] tingling sensation in right hand. Pain in antecubital fossa was attributed to interstitial spilling. Local heat was applied.

Six and a quarter hours after injection, fingers and wrist had become acutely flexed, and hand white and cold. Radial pulse absent, brachial artery pulsating just above elbow-joint but not below it. Entire hand and forearm completely anæsthetic.

On exploration brachial artery was found normal to 2 in. above bifurcation, then passed through a sausage-like tumour of extravasated blood. This was not tense, and further exposure of vessel showed also extravasation of blood into adventitia. Lumen was filled with thrombus to bifurcation and beyond.

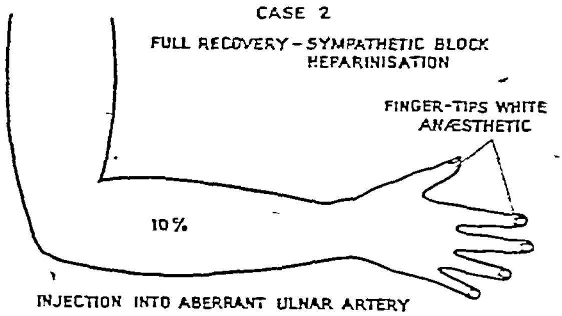
Arterectomy.—1½ in. of brachial artery resected, and thrombus from radial and ulnar arteries extracted.

Postoperative Course.—Left hand and right leg immersed in water-bath at 112°F in attempt to force collateral circulation. Next day, some skin warmth on upper third of forearm, with sensation present to this point. "Spasm" of flexor muscles no longer present. Line of demarcation began to form, complete by eighth day; line extended from 4 in. below elbow on lateral side upwards to elbow-joint medially. Impossible to save joint. Amputation through arm on fifteenth day after injection (see fig. 4).

Extensive arterial thrombosis swiftly sealed the fate of the limb. The brachial artery can usually be ligated with impunity, if the collateral vessels are undamaged. It therefore appears that both the collateral branches and the main distal channels continued to be blocked by soft thrombus. Arterectomy certainly did not relieve so-called "collateral vessel reflex spasm"; the warmth of the skin of the upper forearm indicates that this could, in any event, never have been complete. The large periarterial hæmatoma is to be expected after arterial puncture, but is an unusual finding compared with other cases. A 5% solution is reported to have been used, which makes such a disastrous end-result unusual.

Case 2.—A soldier, aged 45, was operated on for depressed fracture of malar bone. A 10% solution of a "new thiobarbiturate closely related both clinically and pharmacologically to pentothal" was injected, exact amount not recorded. Immediate complaint of severe pain in hand and arm (notes report "solution was injected into an aberrant superficial ulnar artery").

A few seconds after injection, ulnar half of hand and ulnar border of forearm became fiery red. Reaction subsided rapidly: replaced by mottled pallor. Immediate brachial-plexus block done ("satisfactory vasodilatation obtained"). Operation continued under cyclopropane anæsthesia.



CASE 2
FULL RECOVERY - SYMPATHETIC BLOCK HEPARINISATION
FINGER-TIPS WHITE ANÆSTHETIC
10%
INJECTION INTO ABERRANT ULNAR ARTERY

Fig. 5.

At end of operation intravenous saline drip, containing heparin, started; both arms placed in hot-water baths, and patient packed with hot-water bottles. Some three hours after operation, hand again blanched, and tips of the third, fourth, and fifth fingers presented white patches; fingers felt numb to patient. On exposure, ulnar side of hand became distinctly colder than rest of hand and arm. Pulsation present in main arteries.

Sympathetic block of right stellate ganglion now done with 20 ml. of 2½% procaine hydrochloride in 1/1000 amethocaine; posterior approach used, and Horner's syndrome obtained. Much vasodilatation of right upper extremity followed, blanching of ulnar side of hand disappeared, and hand became warm.

Intense transient vasoconstriction, particularly of the distal arterioles, may follow and lead possibly to the trapping or the delay of some of the solution in the distal arterial tree. Wilkins et al. (1938) have shown that various stimuli, such as pinprick, taking a deep breath, or solving a mental problem, will temporarily decrease the blood-flow to the digits to as much as a twentieth of the previous level, independent of any alterations in systemic pressure. This does not happen with the sympathectomised limb and has some bearing on "post-accident" treatment.

Two of the patients (see below) developed shock after the intra-arterial injection, with poor pulse on the opposite limb also, and carpopedal spasm. This may be due to the pain, but severe vasomotor reactions have been described in arteriography with organic iodine compounds. Even intravenous solutions are not without risk, for intravenous pyelography, usually regarded as absolutely safe, has a mortality: Prendergrass et al. (1942) collected 26 deaths in 661,800 such examinations—an incidence of 0·0039%.

Idiosyncrasy or hypersensitivity to thiopentone has been described by Hunter (1943) and Hoenigsberger (1943) has recorded sudden collapse. I witnessed the sudden death, after an injection of thiopentone 0·5 g., of a perfectly healthy young soldier undergoing a minor finger operation. Necropsy did not reveal any cause, but in view of the vasomotor reactions with the intra-arterial injection it obviously becomes important to examine the forearm vessels in any such tragedies. Lundy (1942) declares "a certain number of fatalities are attributable to intra-arterial puncture"—though the immediate collapse makes it difficult to agree with the contention that death was due to "delayed return into the stream."

Area Affected

Six of the twelve cases ended with arm or forearm amputation; two with loss of fingers; two suffered severe nerve effects, with associated Volkmann's contracture of the interossei muscles of the thenar space in one case. The white hand—palm and dorsum—and the cyanosed fingers were early confirmatory signs of the accident. Such rapid cyanosis of the fingers, as Lewis (1936) has shown, does not indicate venous spasm or arrest, but implies a sluggish arterial circulation in a warm hand, leading to rapid reduction of oxyhæmoglobin. Some of the fingers soon became dark purple; these fingers ultimately suffered most. Others remained ashen grey.

Massive gangrene of the limb followed extensive thrombosis in the major vessels. Where these escaped, the ultimate damage depended on the direction of flow of the thiopentone; if this was swept into the muscles, the fingers were often spared. On anatomical grounds (see below)—and this is confirmed by clinical experience—inadvertent injection into the easily mistaken superficial ulnar artery is less likely to lead to the solution reaching and affecting the brachial artery bifurcation; the prognosis is thus better, for the entire limb blood-supply is not jeopardised.

Skin Patches

Several of the cases showed, besides the hand and finger involvement, mottled bluish-green patches in the skin of the forearm, round the elbow-joint, and in the arm well above the site of injection. Some of these patches merely blistered, being filled with clear or serosanguineous fluid; in other patches the skin died and sequestered, leaving punched sloughing ulcers.

Similar patches and ecchymotic areas have been observed in disasters consequent on arteriography. Lambret (1935) and Leclerc (1935) observed violet plaques, regarded as due to cutaneous and subcutaneous hæmorrhages, on the skin of the lower abdominal wall, following femoral arteriography; Leveuf (1935) and Wagner (1944) described this following use of iodoxyl for brachial arteriography. The workers interpreted these patches as due to seco spread of thrombosis from the main vessel to the cutaneous branches.

Thrombosis of the brachial artery can be exclud the thiopentone cases, for in some with patches subse operation showed no such clot. These patches a to be due to the direct local effect of the thiope solution shunted into the skin vessels. The wo Freudenthal (1924) favours this, for he showed th the patches of skin gangrene observed after the acci injection of bismuth into a gluteal artery, the bl of the cutaneous vessels by bismuth-salt crystals be demonstrated by microscopy.

Limb Œdema, Muscle Death, Nerve Effects

A striking feature has been the extensive œde hand and forearm in some of the cases; this m evident within two hours and well-marked withi hours, by which time it may have extended abo site of injection. When the forearm was explored muscles bulged on incision of the fascia but w normal colour, and the œdema appeared not to interfered with their blood-supply. Œdema of m appeared to be responsible for the flexion of the in some of the cases, for it was noted that these still be straightened passively. In one case such straightening became impossible at the end of six the fingers being rigidly flexed and contracted— state of rigor mortis, like the Volkmann's isch contracture of muscle. This is an important ob tion (Johnson 1946), for it confirms Lewis's opin muscle cannot withstand complete ischæmia more than six hours. Dissection of three of the after amputation showed the extensor muscles, as as the flexor group, to be necrotic. This also i important finding, for the extensor muscles have a blood-supply through the profunda vessels, and one w expect these to survive, as they often do in the Volk contracture following trauma. It is likely, thoug have no histological evidence for this, that the thiope solution spread into and thrombosed the dorsal osseous artery on its extensor path as well, and blocked the linking distributing flow of the pro vessels. It emphasises the need for a closer study o such amputated arms.

Study of the extent of thrombosis of forearm v is also important, for it helps to explain the nerve e in these cases. Adams (1942) has shown that major nerves, as they traverse the forearm, re branches of supply from the main arteries; interfe with the blood-supply will interfere with nerve co tion (Holmes et al. 1944, Bentley and Schlapp 1 The interosseous branch of the ulnar artery is partic important in its blood-supply to the median n These facts help to explain the anæsthesia and atr of the intrinsic muscles of the hand that devel in cases 4 and 8. Ischæmia of the nerve-trunks sequent on the arterial thrombosis, rather than the action of thiopentone on the blood-supply of the mu seems here to have been responsible for the nerve le in the hand.

It is of some importance that œdema was never conspicuous in these two cases, for Parkes (1945) brought evidence to show that compression by œd may be sufficient to arrest the blood-supply to nerves and yet not affect pulse and nutrition in distal part of the limb. His conclusions are base the observations of Lewis et al. (1931), who have sh that nerves may be more readily rendered isch because the blood-supply of their feeding branches ca obliterated by pressures as low as 60–70 mm. Hg. work of Parkes indicates that, if the œdema after in arterial injection of thiopentone becomes severe, fa

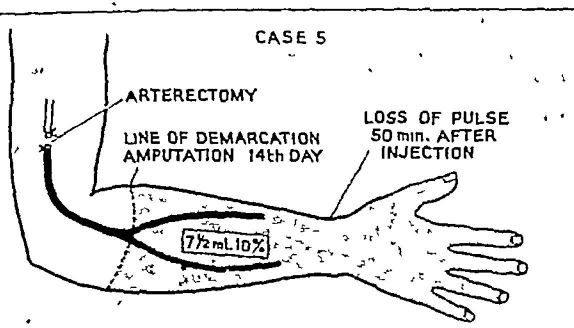


Fig. 8.

discoloration of tip of index finger. Intrinsic muscles of d appeared to be grossly affected, thenar muscles being k, and interossei and adductors of thumb "apparently npletely gone."

urther history of this case has been impossible to trace, the anæsthetist informs me "he has heard that patient de complete recovery" (see fig. 7).

The loss of forearm pulses after the operation suggests it the patient had an arterectomy. After a brachial erectomy the radial pulse usually returns within a r days (4 days as a rule). The non-return of the lses indicates a continued blocking of the radial ery by soft thrombus; this is suggested too by the port of a good ulnar pulse before operation. The reasing anæsthesia of the hand suggests some post-erative extension of the thrombosis. The paresis the intrinsic muscles of the hand and their later covery indicate some blocking of the vascular supply the main nerve-trunks. It might be suggested that the edian nerve at the elbow received the thiopentone solu-on; but the entire hand was involved and the fore-m muscles were not affected. We can only assume iat the injection was intra-arterial, the complete bsence of pain being unusual. The early muscle spasm iggests that much of the solution may have taken its ath via the forearm muscles, and that may explain the rtunate happy result with such a large intra-arterial jection.

Case 5.—This case has been reported in detail by Johnson 946). Male, aged 37, with buttock abscess. Needle entered ito "median cephalic vein." Venous-looking blood aspirated, od injection of a 10% solution of pentothal begun. After 5 ml. "patient began to move about, this was taken to mean iat he was tasting sulphur"; injection continued.

After about 7·5 ml. had been given, patient groaned and ioved, but there was no indication of pain in the hand. njection now stopped; patient lost consciousness; abscess ncised. Anæsthetist noted area of petechial hæmorrhages ibout 3 in. broad above elbow, where nurse had compressed um.

Recovery of consciousness apparently rapid—60–90 sec. Patient groaned and complained of pain in both arms, especially the left. Left hand was pale and bluish; both hands and feet went into typical carpopedal spasm. Both radial pulses present, equal, and of good volume. In the ward, 50 min. after operation, pulse had disappeared; fore-arm white and flaccid below elbow. (All spasm had dis-appeared from extremities.) Meanwhile, arm had been placed under electric cradle, and papaverine, carbachol, and alcohol administered.

No arterial pulsation below a point 3 in. above the elbow could be detected. Complete loss of voluntary movement in wrist and fingers, but passive movements full and painless, and such passive movement did not increase pain.

Six hours after injection, thumb had become flexed across palm, and fingers were beginning to contract. Static blood could be observed in capillaries; no evidence of capillary irculation. It was decided to explore the vessel, and this was done under general anæsthesia.

At a point 3 in. above site of injection brachial artery pulsa-ion ended abruptly. Narrow band of demarcation well above site of injection. Below site of constriction vessel was slightly dilated and blue, obviously thrombosed.

Aspiration showed no fluid blood present. About 5 in. of artery was removed; it was filled with clot. No definite puncture site could be seen, nor was there staining or bleb in adventitia; no periarterial extravasation of blood. Patient was given heparin 10,000 units intravenously into other arm. Unsuccessful attempt to block cervical sympathetic by posterior approach.

Two days later some sensation had returned to upper third of forearm; skin here pink, but blue and sensationless below, indicating appearance of an early line of demarcation. Below this, arm showed all signs typical of dry gangrene.

Two weeks after original injection there was a well-formed line of demarcation extending $4^1/_2$ in. down radial side, and 3 in. on ulnar side, below elbow. Amputation eventually performed just above this level (see fig. 8).

Extensive arterial thrombosis was clearly the cause of limb death. The early maintenance of the pulse indicates that arterial spasm was not responsible for the thrombosis. Blistering at the site where the nurse had compressed the arm suggests that this may have been too vigorous, cut off the pulse, and permitted the higher injection of the solution. The onset of Volkmann's contracture six hours after the injection is valuable information; the previous painless passive movements possible indicate that the muscles before this time were still alive. Arterectomy made no difference to the ultimate result. In view of the carpopedal muscular spasms shortly after the injection, it is of interest to note that Macintosh and Heyworth (1943) reported that after an injection of 0·75 ml. of thiopentone into a cat's iliac arteries similar muscular contraction in all four limbs, of short duration, followed.

Case 6.—Female, 43, abdominoperineal operation. Given 10 ml. of thiopentone. "At the end of the operation the right arm was observed to be cold and pallid, as if arterial blood had been cut off." Thought possibly due to faulty position of arm on table. Both radial and ulnar pulses absent, and pulsation could be felt in brachial artery only high up—2 in. below axilla. "2% procaine was injected, in case this might be arterial spasm"; circulation did not improve.

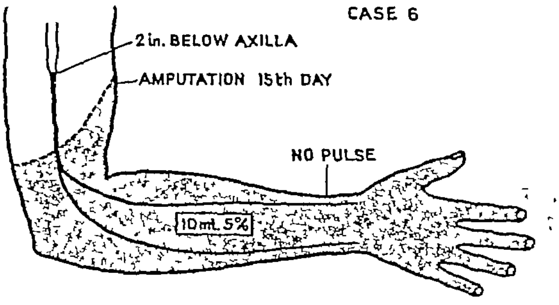

Fig. 9.

Four hours after operation, cubital fossa was explored under local anæsthesia, and vessel was exposed from axilla to elbow. Brachial artery was anomalous, bifurcating about 1 in. above fossa; radial and ulnar arteries superficial, ulnar artery then disappeared beneath lacertus fibrosus to enter forearm.

Site of injection was clearly found in brachial artery, which was opened and found completely filled with clot; thrombosis extended from $1^1/_2$ in. below axilla far into fore-arm along the two branches. These are the only operation notes.

Dry gangrene set in, fingers clawed, forearm became partially mummified, and a line of demarcation appeared extending from lateral side just above elbow round arm to 2 in. below axilla. Skin of upper arm looked healthy, presumably owing to circulation in profunda branch of brachial artery.

There being no urgent toxic symptoms, amputation was delayed until 15 days after original injection (see fig. 9).

A 5% solution of thiopentone was used; the resultant thrombosis was most extensive, blocking both the superior and inferior ulnar collateral vessels and leading to the formation of the line of demarcation above the

Heparinisation continued; clotting-time, two hours after stellate block, 27 min. Patient now began to cough up considerable quantities of bright-red blood, which did not clot; apex of lung must have been injured during sympathetic block. Heparin stopped. Radiography showed nothing abnormal in chest.

Next morning, hæmoptysis had stopped, and clotting-time was normal. No further disturbances in hand.

Some fifteen days after original accident patient complained of dyspnœa on lying flat. Radiography showed large retro-pleural mass in relation to apex of right lung, extending posteriorly down to tenth intercostal space.

Aspiration produced 150 ml. of dark unclotted blood. Dyspnœa disappeared immediately, and hæmatoma was gradually absorbed (confirmed by radiography). (See fig. 5.)

The full vasodilatation that followed sympathetic block is an obvious pointer that this will be a useful measure in the management of such cases. Since the main vessels were pulsating fully thrombosis can be excluded, and the beneficial effects of the sympathetic block must be due to its effect in releasing spasm in the distal arterioles. Two further facts of significance are: (1) brachial-plexus block was as effective as the more difficult posterior sympathetic block; and (2) the arteriolar spasm recurred within four hours. Sympathetic block in a heparinised patient is well shown to be hazardous.

Case 3.—An adult, with gastric ulcer, admitted for partial gastrectomy was given heavy spinal 'Nupercaine,' followed by 4 ml. of 10% thiopentone and then nitrous oxide and oxygen. Injection reported as painful, hand became white, and on skin of forearm irregular blue patches developed. Radial pulse full and continued thus for whole day. Entire hand anæsthetic, as also distal half of ulnar aspect of forearm. Motor power poor: feeble finger flexion and extension possible; wrist could be held against gravity; but pronation and supination impossible. Flexion and extension of elbow good.

Next day circulation improving, pulse reported as "good," but forearm muscles firm and indurated. Circulation in fingers gradually improved.

On fifteenth day after injection, sudden loss of radial pulse; hand became cold and white, and finger and wrist movements impossible. Four days later mummification began. Oblique irregular line of demarcation developed in upper third of forearm.

Forearm amputation, thirty days after injection, made possible by dissecting out muscles, which were all avascular except for biceps and triceps; 2-in. bone stump was left. Ulnar and radial arteries and last 3 in. of brachial artery thrombosed. Normal pulsating segment not observed. Accompanying venæ comites not thrombosed. A useful small elbow stump saved (see fig. 6).

Particular features are: (1) only 4 ml. of a 10% solution was used; and (2) the radial pulse suddenly vanished on the fifteenth day. The loss of finger movement and the induration of the forearm muscles suggest that these were already dead before the final loss of the radial pulse. The onset of the late thrombosis is discussed below. A line of demarcation was waited for, and it is to be noted that there were no renal or other systemic effects from absorption of dead muscle tissue, as has been reported to follow arterial thrombosis with muscle death in the legs (Guthkelch 1943, Bywaters and Stead 1945). The saving of even a small elbow stu by dissecting out the dead muscles, was an excel manœuvre; for, contrary to the teaching of s surgical textbooks this small stump may prove of utmost importance as regards the subsequent typ prosthesis (Gillis 1945).

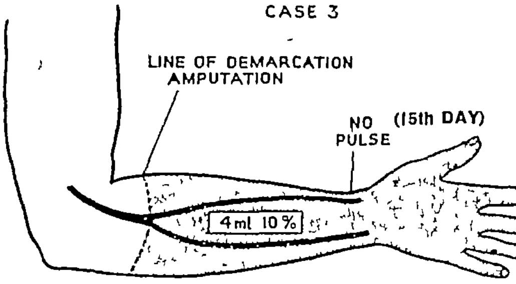

Fig. 6.

Case 4.—A male, aged 22, admitted for mastoidecto 10% thiopentone used. "Vein in antecubital fossa, right stood out well and felt superficial." Needle inserted vessel, arm being fully extended. Piston withdrawn sho no blood; needle pushed on another $^1/_8$ in., piston withdr and blood flowed freely into syringe; blood did not ap unduly red. Thiopentone 3 ml. injected fairly quickly; pause; and, since patient was not sleepy, a further am was given slowly.

In all about 8 ml. was given (last 2 ml. not injected). T was no difficulty in injecting and no swelling at site; pat did not complain of any pain or discomfort. The only t noted was that patient took longer than usual befor became unconscious.

Taken into theatre, and airway inserted. He did not to like airway; nitrous oxide, ether, and oxygen contin and intratracheal tube passed. Breathing became shallow, *patient appeared pale; head of table was lowered.* feeling for radial pulse, condition of hand was first no No pulse could be felt, though brachial pulse showed deterioration. Hand was in carpal spasm and white, cyanotic patches. Nitrous oxide was reduced and oxy increased; opposite arm was placed in hot water.

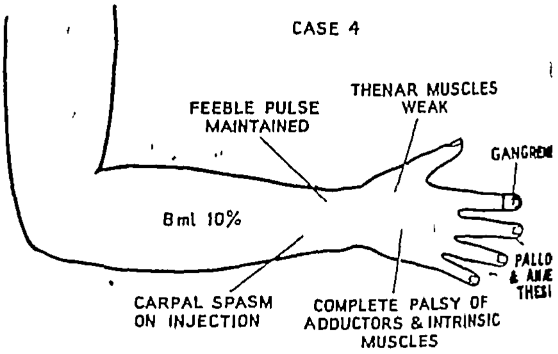

Fig. 7.

After about 10 min. muscular spasm relaxed a little, still no improvement in colour of hand. Radial pulse returned, but not so good as its fellow. At end of operat radial pulse just palpable, colour of hand fair, but n somewhat cyanosed.

On return to ward, unaffected arm was placed in a bath, 120°F, a hot cradle was applied to legs, and 150 mg nicotinic acid given by mouth.

Three hours after operation, both radial and ulnar pu easily felt; but pallor and coldness of index and ring fing continued—other fingers of good colour. Barbitone gr whisky 4 oz., and hot bath continued.

Nine hours after injection, pallor and coldness of ring little fingers still present. Radial pulse just palpable, ul pulse "quite good." Pain (not severe) and numbness fingers and thenar eminence. Patch of discoloration o anatomical snuff-box.

Ten hours after original injection, *exploration of* an cubital fossa under local anæsthesia. Difficult to det accurately the anatomy. Two small arteries with satel veins were first encountered; pulsation was feeble; sm segments of both vessels were removed. Deeper dissect now continued, and a further small parent artery stron pulsating was seen (presumably brachial artery)—sm segment excised.

At end of operation patient thought hand felt bett Hand was encased in wool; hot cradle to legs and immer *of opposite arm were continued.*

Next day hand and fingers became swollen, all fingers n of good colour except tip of index finger, which alone v anæsthetic. Radial and ulnar pulses impalpable, but lit complaint of pain. Nicotinic acid by mouth and papaver three times a day continued.

Swelling of hand gradually subsided, movements of fing became full, and colour of hand returned to normal exc

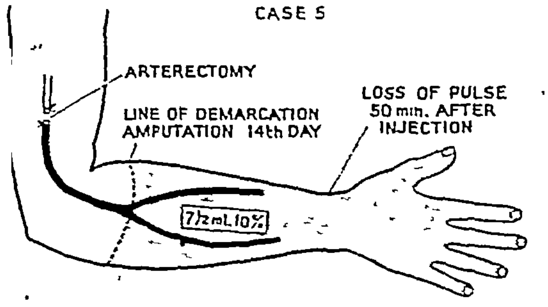

Fig. 8.

scoloration of tip of index finger. Intrinsic muscles of appeared to be grossly affected, thenar muscles being and interossei and adductors of thumb "apparently letely gone."

ther history of this case has been impossible to trace, he anæsthetist informs me "he has heard that patient complete recovery" (see fig. 7).

e loss of forearm pulses after the operation suggests the patient had an arterectomy. After a brachial ectomy the radial pulse usually returns within a days (4 days as a rule). The non-return of the s indicates a continued blocking of the radial y by soft thrombus; this is suggested too by the rt of a good ulnar pulse before operation. The asing anæsthesia of the hand suggests some post-ative extension of the thrombosis. The paresis he intrinsic muscles of the hand and their later very indicate some blocking of the vascular supply ie main nerve-trunks. It might be suggested that the ian nerve at the elbow received the thiopentone solu-; but the entire hand was involved and the fore-muscles were not affected. We can only assume the injection was intra-arterial, the complete ence of pain being unusual. The early muscle spasm gests that much of the solution may have taken its h via the forearm muscles, and that may explain the umate happy result with such a large intra-arterial ction.

ase 5.—This case has been reported in detail by Johnson 16). Male, aged 37, with buttock abscess. Needle entered "median cephalic vein." Venous-looking blood aspirated, injection of a 10% solution of pentothal begun. After ml. "patient began to move about, this was taken to mean he was tasting sulphur"; injection continued.

fter about 7·5 ml. had been given, patient groaned and ved, but there was no indication of pain in the hand. ection now stopped; patient lost consciousness; abscess ned. Anæsthetist noted area of petechial hæmorrhages ut 3 in. broad above elbow, where nurse had compressed a.

Recovery of consciousness apparently rapid—60–90 sec. tient groaned and complained of pain in both arms, pecially the left. Left hand was pale and bluish; both nds and feet went into typical carpopedal spasm. Both lial pulses present, equal, and of good volume. In the rd, 50 min. after operation, pulse had disappeared; fore-n white and flaccid below elbow. (All spasm had dis-peared from extremities.) Meanwhile, arm had been placed ler electric cradle, and papaverine, carbachol, and alcohol ninistered.

No arterial pulsation below a point 3 in. above the elbow ld be detected. Complete loss of voluntary movement wrist and fingers, but passive movements full and painless, such passive movement did not increase pain.

ix hours after injection, thumb had become flexed across m, and fingers were beginning to contract. Static blood ld be observed in capillaries; no evidence of capillary ulation. It was decided to explore the vessel, and this done under general anæsthesia.

At a point 3 in. above site of injection brachial artery pulsa-n ended abruptly. Narrow band of demarcation well ve site of injection. Below site of constriction vessel was htly dilated and blue, obviously thrombosed.

Aspiration showed no fluid blood present. About 5 in. of artery was removed; it was filled with clot. No definite puncture site could be seen, nor was there staining or bleb in adventitia; no periarterial extravasation of blood. Patient was given heparin 10,000 units intravenously into other arm. Unsuccessful attempt to block cervical sympathetic by posterior approach.

Two days later some sensation had returned to upper third of forearm; skin here pink, but blue and sensationless below, indicating appearance of an early line of demarcation. Below this, arm showed all signs typical of dry gangrene.

Two weeks after original injection there was a well-formed line of demarcation extending 4½ in. down radial side, and 3 in. on ulnar side, below elbow. Amputation eventually performed just above this level (see fig. 8).

Extensive arterial thrombosis was clearly the cause of limb death. The early maintenance of the pulse indicates that arterial spasm was not responsible for the thrombosis. Blistering at the site where the nurse had compressed the arm suggests that this may have been too vigorous, cut off the pulse, and permitted the higher injection of the solution. The onset of Volkmann's contracture six hours after the injection is valuable information; the previous painless passive movements possible indicate that the muscles before this time were still alive. Arterectomy made no difference to the ultimate result. In view of the carpopedal muscular spasms shortly after the injection, it is of interest to note that Macintosh and Heyworth (1943) reported that after an injection of 0·75 ml. of thiopentone into a cat's iliac arteries similar muscular contraction in all four limbs, of short duration, followed.

Case 6.—Female, 43, abdominoperineal operation. Given 10 ml. of thiopentone. "At the end of the operation the right arm was observed to be cold and pallid, as if arterial blood had been cut off." Thought possibly due to faulty position of arm on table. Both radial and ulnar pulses absent, and pulsation could be felt in brachial artery only high up—2 in. below axilla. "2% procaine was injected, in case this might be arterial spasm"; circulation did not improve.

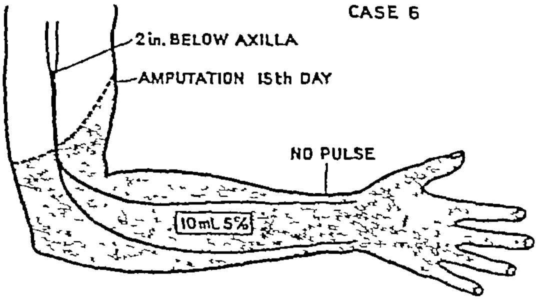

Fig. 9.

Four hours after operation, cubital fossa was explored under local anæsthesia, and vessel was exposed from axilla to elbow. Brachial artery was anomalous, bifurcating about 1 in. above fossa; radial and ulnar arteries superficial, ulnar artery then disappeared beneath lacertus fibrosus to enter forearm.

Site of injection was clearly found in brachial artery, which was opened and found completely filled with clot; thrombosis extended from 1½ in. below axilla far into fore-arm along the two branches. Those are the only operation notes.

Dry gangrene set in, fingers clawed, forearm became partially mummified, and a line of demarcation appeared extending from lateral side just above elbow round arm to 2 in. below axilla. Skin of upper arm looked healthy, presumably owing to circulation in profunda branch of brachial artery.

There being no urgent toxic symptoms, amputation was delayed until 15 days after original injection (see fig. 9).

A 5% solution of thiopentone was used; the resultant thrombosis was most extensive, blocking both the superior and inferior ulnar collateral vessels and leading to the formation of the line of demarcation above the

Heparinisation continued; clotting-time, two hours after stellate block, 27 min. Patient now began to cough up considerable quantities of bright-red blood, which did not clot; apex of lung must have been injured during sympathetic block. Heparin stopped. Radiography showed nothing abnormal in chest.

Next morning, hæmoptysis had stopped, and clotting-time was normal. No further disturbances in hand.

Some fifteen days after original accident patient complained of dyspnœa on lying flat. Radiography showed large retropleural mass in relation to apex of right lung, extending posteriorly down to tenth intercostal space.

Aspiration produced 150 ml. of dark unclotted blood. Dyspnœa disappeared immediately, and hæmatoma was gradually absorbed (confirmed by radiography). (See fig. 5.)

The full vasodilatation that followed sympathetic block is an obvious pointer that this will be a useful measure in the management of such cases. Since the main vessels were pulsating fully thrombosis can be excluded, and the beneficial effects of the sympathetic block must be due to its effect in releasing spasm in the distal arterioles. Two further facts of significance are: (1) brachial-plexus block was as effective as the more difficult posterior sympathetic block; and (2) the arteriolar spasm recurred within four hours. Sympathetic block in a heparinised patient is well shown to be hazardous.

Case 3.—An adult, with gastric ulcer, admitted for partial gastrectomy was given heavy spinal 'Nupercaine,' followed by 4 ml. of 10% thiopentone and then nitrous oxide and oxygen. Injection reported as painful, hand became white, and on skin of forearm irregular blue patches developed. Radial pulse full and continued thus for whole day. Entire hand anæsthetic, as also distal half of ulnar aspect of forearm. Motor power poor: feeble finger flexion and extension possible; wrist could be held against gravity; but pronation and supination impossible. Flexion and extension of elbow good.

Next day circulation improving, pulse reported as "good," but forearm muscles firm and indurated. Circulation in fingers gradually improved.

On fifteenth day after injection, sudden loss of radial pulse; hand became cold and white, and finger and wrist movements impossible. Four days later mummification began. Oblique irregular line of demarcation developed in upper third of forearm.

Forearm amputation, thirty days after injection, made possible by dissecting out muscles, which were all avascular except for biceps and triceps; 2-in. bone stump was left. Ulnar and radial arteries and last 3 in. of brachial artery thrombosed. Normal pulsating segment not observed. Accompanying venæ comites not thrombosed. A useful small elbow stump saved (see fig. 6).

Particular features are: (1) only 4 ml. of a 10% solution was used; and (2) the radial pulse suddenly vanished on the fifteenth day. The loss of finger movement and the induration of the forearm muscles suggest that these were already dead before the final loss of the radial pulse. The onset of the late thrombosis is discussed below. A line of demarcation was waited for, and it is to be noted that there were no renal or other systemic effects from absorption of dead muscle tissue, as has been reported to follow arterial thrombosis with muscle death in the legs (Guthkelch 1943, Bywaters and Stead 1945). The saving of even a small elbow by dissecting out the dead muscles, was an exce manœuvre; for, contrary to the teaching of surgical textbooks this small stump may prove of utmost importance as regards the subsequent type prosthesis (Gillis 1945).

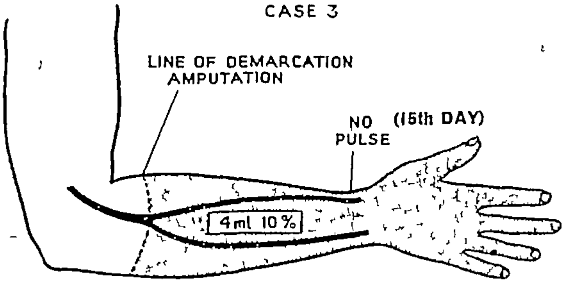

Fig. 6.

Case 4.—A male, aged 22, admitted for mastoidectom 10% thiopentone used. "Vein in antecubital fossa, right a stood out well and felt superficial." Needle inserted o vessel, arm being fully extended. Piston withdrawn sho no blood; needle pushed on another $^1/_8$ in., piston withdra and blood flowed freely into syringe; blood did not app unduly red. Thiopentone 3 ml. injected fairly quickly; th pause; and, since patient was not sleepy, a further amo was given slowly.

In all about 8 ml. was given (last 2 ml. not injected). Th was no difficulty in injecting and no swelling at site; pati did not complain of any pain or discomfort. The only th noted was that patient took longer than usual before became unconscious.

Taken into theatre, and airway inserted. He did not s to like airway; nitrous oxide, ether, and oxygen contin and intratracheal tube passed. Breathing became shallow, a patient appeared pale; head of table was lowered. feeling for radial pulse, condition of hand was first no No pulse could be felt, though brachial pulse showed deterioration. Hand was in carpal spasm and white, cyanotic patches. Nitrous oxide was reduced and ox increased; opposite arm was placed in hot water.

Fig. 7.

After about 10 min. muscular spasm relaxed a little, still no improvement in colour of hand. Radial pulse returned, but not so good as its fellow. At end of operat radial pulse just palpable, colour of hand fair, but somewhat cyanosed.

On return to ward, unaffected arm was placed in a bath, 120°F, a hot cradle was applied to legs, and 150 mg. nicotinic acid given by mouth.

Three hours after operation, both radial and ulnar pul easily felt; but pallor and coldness of index and ring fing continued—other fingers of good colour. Barbitone gr. whisky 4 oz., and hot bath continued.

Nine hours after injection, pallor and coldness of ring little fingers still present. Radial pulse just palpable, ul pulse "quite good." Pain (not severe) and numbness fingers and thenar eminence. Patch of discoloration o anatomical snuff-box.

Ten hours after original injection, exploration of an cubital fossa under local anæsthesia. Difficult to de accurately the anatomy. Two small arteries with satell veins were first encountered; pulsation was feeble; Fr segments of both vessels were removed. Deeper dissecti now continued, and a further small parent artery stron pulsating was seen (presumably brachial artery)—sm segment excised.

At end of operation patient thought hand felt be Hand was encased in wool; hot cradle to legs and immer of opposite arm were continued.

Next day hand and fingers became swollen, all fingers of good colour except tip of index finger, which alone anæsthetic. Radial and ulnar pulses impalpable, but lit complaint of pain. Nicotinic acid by mouth and papaver three times a day continued.

Swelling of hand gradually subsided, movements of fing became full, and colour of hand returned to normal exc

Later, some of contracted muscle mass was excised by his urgeon; section showed complete muscle necrosis (fig. 14).

I again saw this patient some $2^{1}/_{2}$ years after original njection. He then complained that with cold the fingers went a dirty grey, movements became difficult, and finger numbness prevented him from using hand. On any heavy work hand went dead white.

The fingers do not appear to have been affected, xcept for later secondary effects; this suggests that the hiopentone was embolised in the main to the forearm nuscles and thenar space. Death of the muscles of the henar space indicates that the radial artery must have een responsible for most of the supply, and that spread f the thrombosis along this vessel into the distributing ranches blocked the ulnar-artery anastomosis. This s very much akin to the march of events with an arterial mbolus, distal clot blocking the collateral vessel path. The hand anæsthesia, which apparently took well over 18 months to recover, has two possible explanations: (1) forearm œdema, with compression of the vascular supply of the nerve-trunks (the œdema was, however, never very extensive); and (2) spasm or thrombosis of the vessels of supply to the medial and ulnar nerves. The loss of power in all the intrinsic muscles of the hand suggests the latter ætiology—ischæmia of the main nerve-trunks. The "Raynaud's phenomenon" sensitivity to cold is an interesting observation which has not been encountered in any of the other cases. There has, however, been no opportunity for the late examination of the recovered patients.

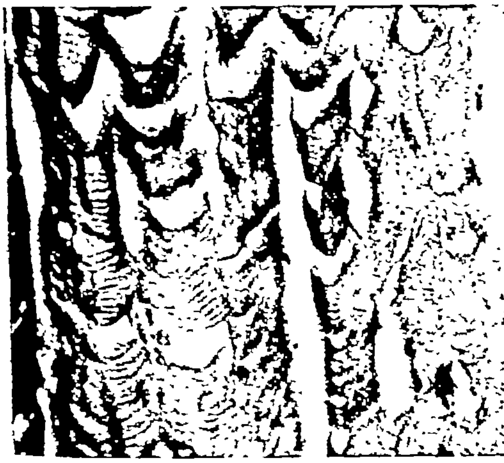

Fig. 14—Biopsy specimen showing coagulation necrosis of thenar muscle in case 8.

Case 9.—Male, 52, with prolapsed iris. Anæsthesia induced with thiopentone. 10% solution. The "vein" was superficial and easily entered on the first attempt. After 4 ml. complaint of severe pain in arm—"you're breaking my arm." Aspiration showed free blood-flow, injection continued. Noted "he took a little longer to go under than usual."

On recovery from anæsthetic, pain in arm was first thing complained of. Nothing abnormal noted. Some 4 hours later, thumb and index finger were whiter than rest of hand, and a bulla $^{1}/_{2}$ in. in diameter, filled with clear fluid, had appeared on thenar eminence.

Next morning, thumb and index finger dusky, and patient had severe pain in forearm and a "sensation as of tight band" round distal phalangeal joints of thumb and index finger.

By evening, distal phalanges were dark purplish-black, fading to dusky grey over second phalanx. On thumb, discoloration extended farther on palmar aspect than on dorsum, reaching thenar eminence, where there was purplish-yellow blotchy discoloration. Hand and forearm were much swollen up to elbow. Generalised erythema of forearm, œdematous area being slightly warmer than on other side. Thumb and index phalanges anæsthetic and cold to touch.

Forty-eight hours after injection, irregular patches were present over forearm, largest being over radial border. These patches later developed purplish central area. Radial pulse felt normal and arterial wall in "good condition."

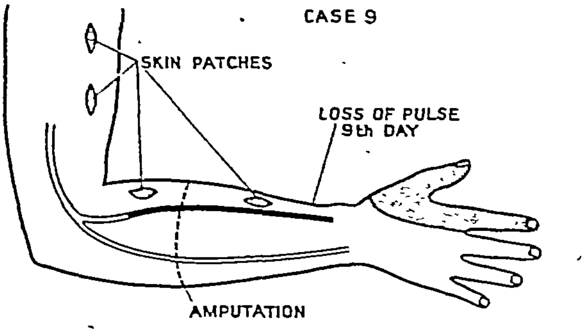

Fig. 15.

Hand continued thus for 5 days; thumb and index finger then became black and gangrenous, and skin patches on forearm began to slough.

Nine days after injection, radial pulse, which had remained normal, "suddenly" disappeared. Cubital fossa was therefore explored under brachial-plexus anæsthesia. Basilic vein found thrombosed. Radial artery thread-like and did not pulsate; ulnar branch pulsating.

Brachial artery was then explored; its pulsations were normal, and vessel was opened to extract any clot. Intima appeared normal, no clot was found, and vessel was resutured. One inch of radial artery was resected: there was no return bleeding from distal end.

Microscopical examination showed intimal swelling and fibrin filling vessel lumen, but channel still present.

Some 6 weeks after injection, thumb and index were amputated. Unfortunately infection supervened, and final amputation had to be performed through forearm some 3 months after original accident (see figs. 15–17).

The original injection was probably in the brachial artery, but it seems that most of the thiopentone spent itself, via the radial artery, in the thumb and index finger. The disappearance of the pulse on the ninth day is not easy to explain, since the vessel was filled with fibrin rather than with clot, a finding to be expected usually where there has been long-continued vascular spasm. Microscopy showed considerable swelling and damage of the intima, which confirms that this vessel carried the brunt of the solution. The sloughing skin patches above and below the site of injection appeared to be due to local effects of thiopentone. An explanation of the high distribution of some of the skin patches on the arm has already been attempted. It is clear that there was thrombosis, at an early stage, of the digital vessels of the thumb and index, for these fingers never became swollen, indicating complete arterial arrest. The finding of a thrombosed cubital vein suggests that this may have been traversed to reach the artery.

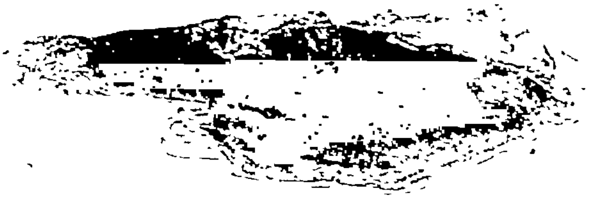

Fig. 16—Gangrenous segment of hand amputated six weeks after intra-arterial thiopentone (case 9).

Case 10.—This case has been reported by Macintosh and Heyworth (1943).

Patient was given 5 ml. of 10% thiopentone into an aberrant ulnar artery.

Thin rubber venous tourniquet and "best-looking vessel" selected. No. 17 needle, blood aspirated, and injection begun at moderate speed. After 5–10 sec. patient complained of very severe pain in whole hand, as "though boiling water elbow. Such high thrombosis can only be explained on the assumption that the high Trendelenburg position, with consequent depression of the shoulder obliterated the pulse during the injection. The solution was thus injected into a non-pulsating vessel, and the high ascent of the solution and the sustained action of the thiopentone were thus made possible.

Case 7.—Man, 51, "highly strung," operation for hammer toe. Thiopentone 10% injected into a vessel on medial side of elbow. After 2 ml. patient indicated that he was "going off." A further 3 ml. then injected; patient now complained of severe pain in hand, saying "it feels as if on fire" and tried to vomit. Needle withdrawn and remaining 5 ml. injected into adjacent vein. Light gas-oxygen and ether continued.

Two hours later, patient looked very pale and was writhing in great pain. Hand cold, fingers ashen, dorsum of palm dead white. Patchy discoloration on ulnar border of arm. Both pulses present; equal blood-pressure readings. Superficial veins in forearm somewhat engorged. No hand œdema, no induration or swelling at elbow to suggest local leakage of thiopentone or blood.

Some two hours later, forearm was much swollen; muscles appeared to be under great tension. Wrist and fingers held semi-flexed; attempts at active or passive movements caused acute pain. Engorgement of superficial veins more pronounced. Both radial pulses present; blood-pressure readings equal in both arms. Ulnar pulse could not be felt in either wrist. Tips of all fingers dusky and did not blanch on pressure. Palm and dorsum still deathly pale; no swelling distal to wrist. Pain of acute burning type, affecting diffusely all fingers and whole hand; patient in agony and unable to lie still.

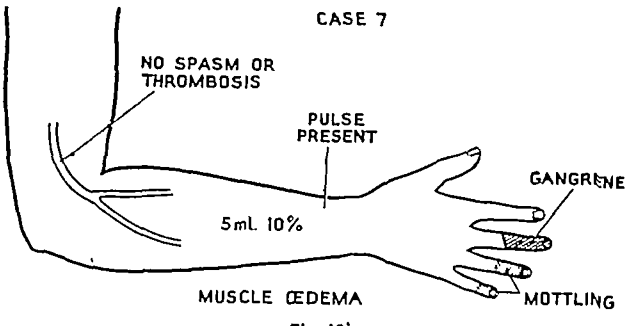

Fig. 10.

Five hours after injection, swelling of forearm rapidly increasing, operation undertaken. Deep fascia incised from medial side of antecubital fossa to 3 in. above wrist. Immediate pronounced bulging of muscles, which were, however, of normal colour. Dissection showed that brachial artery branched high up in upper arm, and radial artery descended superficially just beneath deep fascia. Radial artery, dissected to middle third of forearm, showed strong pulsation throughout its length, with no indication of spasm or thrombosis. Ulnar artery similarly normal.

Circulation in thumb and index appeared to improve. Palm developed a mottled red flush, but dorsum unchanged. Reflex heating started. By next morning circulation of the index and thumb appeared normal; ring and little fingers were a mottled reddish-blue, but middle finger dark blue very black as far as finger knuckle. Pain in hand easier, in middle finger still intense.

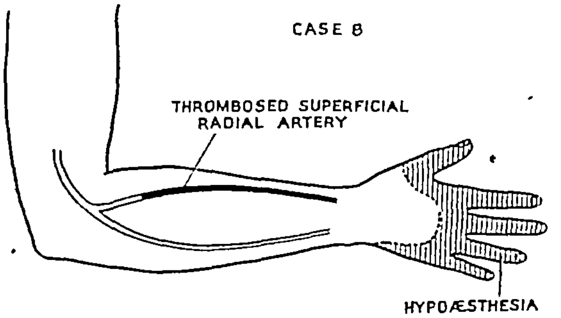

Fig. 11.

Within 48 hours hand regained normal colour, except terminal phalanx of middle finger and tip of ring fin, Middle finger still much discoloured; ring finger showing greyish-blue mottling. Movement and sensation had returned. Dorsum of hand and wrist had, however, become swollen, where previously not swollen; this may have been due to posture, for high elevation caused pain, which was relieved to some extent by horizontal or dependent po

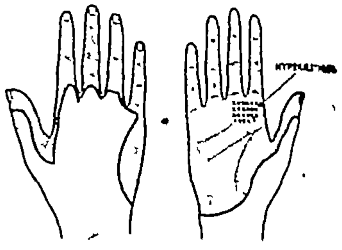

Fig. 12—Area of hypoæsthesia (stippled) hand of case 8 fifteen months after intra-arterial thiopentone.

Ultimate outcome was loss of terminal phalanx of finger only (see fig. 10).

The successful issue in this case is first of all due to the skill and care of the surgeon (Mr. E. B. Jamieson, F.R.C.S.), whose very full notes I am able to relate, and who gave me the opportunity of seeing the patient. Secondly, the enormous muscle œdema appears to indicate that the pathway of most of the solution was fortunately via the forearm muscles; such pronounced early swelling *of the forearm may thus be useful in attempting to assess* the prognosis. The radial pulse was never lost, and the equal blood-pressure readings indicate that there could have been no spasm of a major vessel.

Case 8.—Male, 39, nephrectomy. Details of anæsthesia not available, but according to brief notes "after small pentothal injection there was complaint of pain; the needle therefore was withdrawn and injection continued into opposite arm." According to patient, immediately on injection he had agonising burning pain in the hand. When he awoke he had considerable pain, especially over thenar eminence. Possibility of thiopentone being responsible at that time not entertained.

Two days later, forearm was swollen, but "not the hand." There was "glove anæsthesia" of entire hand, feeble movement of fingers only possible, though wrist movements normal (fig. 11). Because of "glove anæsthesia" the patient was regarded as hysterical, and opinion of neurologist was sought, who noted absence of radial pulse and suggested that thiopentone had been injected into artery.

Fig. 13—Hand of case 8 two and a half years after intra-arterial thiopentone, showing adduction contracture of thumb following necrosis of thenar muscle.

When I first saw patient fifteen months after accident, he said he developed black and blue patches on forearm, which blistered. Healed scars were still present at my examination. Patient complained that he still had much pain at night, and hand felt as if skin was too tight ("like having on a too tight pair of gloves"). There was hypoæsthesia of entire hand, with a small patch of hyperæsthesia in palm (fig. 12). Thumb held in tight adduction (fig. 13), and muscles of thenar interspace and abductor pollicis felt woody hard. Finger movements now full, but fingers showed wasting of pulp, loss of transverse skin ridging, and distorted nail growth; they were warm. Radial pulse absent, and vessel could be traced upwards as a thrombosed cord.

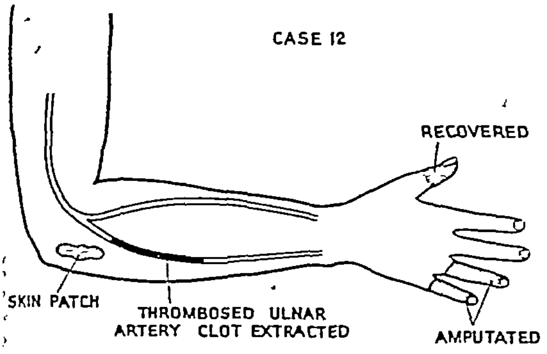

Fig. 20.

Pathologist's Report.—Brachial artery: some endothelial ickening of wall and a little fibrin deposited deep to dothelium.

Radial artery (3 cm. long by 2 mm. broad): endothelial bliferation, and at one point a small mass of fibrin which s clearly present before removal. Rest of arterial lumen tupied by unorganised blood.

Muscle: a small piece, taken at operation, "shows early generate changes, with loss of cross-striation and some normality of staining. There are also places with prolifera- n of sarcolemmal cells. These degenerative changes are ch slighter than has been observed in other ischæmic scle."

After operation, hand became discoloured to middle of rearm, and cold. Three weeks after exploration a forearm putation was done, leaving a $2^1/_2$ in. stump. Pathologist ported "no thrombi in distal smaller arterials," and con- ered that "obliteration responsible for death of limb ok place at some point above site of amputation" (see 19).

Recurring spasms of pain, like those the child had ter discharge from hospital, are often noted in limbs with vere ischæmia. The sudden attack of pain a week ter must indicate an extension of the thrombosis. The ild was playing at the time; experience with arterial ease shows that, in a thrombotic lesion, extension the level of thrombosis may sometimes be precipitated exercise. Late thrombosis on the eighth day is ten seen with venous thrombosis—e.g., in the leg. right (1947) has demonstrated that about that time ter operation there is an increase both in number and "stickiness" of the platelets, and this may be a ponsible factor in the late thrombosis in the thiopentone es. Arterectomy certainly did not relieve the condi- n; the value of this procedure, in the light of perience with other cases, is discussed below.

Case 12.—Reported by C. W. H. Van der Post (1942). ven in all 6 ml. of 10% thiopentone for dilatation and curettage. ncture was difficult. After injection of 1 ml. an immediate d flush spread down arm, and "whole vein down arm was rombosed." Operation was successfully completed.

Next day, terminal phalanx of thumb and two fingers were going gangrenous." Arm œdematous to just above bow, and little and ring fingers insensible to touch and mperature; terminal phalanx of thumb cyanosed, with e or two bullæ in skin. Radial pulse was palpable, and nar artery could be palpated only as far as elbow. Bluish- een patch round inner aspect of elbow.

Surgeon explored elbow under general anæsthesia and found anomalous origin of ulnar artery, which arose from brachial tery a full inch above elbow and then passed superficially flexors of forearm. Ulnar artery was opened just above bow, and thrombus about $^3/_4$ in. long and $^1/_8$ in. thick s extracted; vessel incision was sutured.

Next day, some improvement of arm, fingers becoming rm, and sensation returned. Convalescence interrupted severe uterine hæmorrhage. Finally terminal phalanges ring and little fingers were lost, whereas thumb recovered e fig 20).

Injection was into the easily mistaken superficial nar artery. Arteriotomy, with extraction of the clot, seems to have been valuable, for the ultimate result can be regarded as satisfactory. The immediate formation of thrombus fits in very well with the march of events in case 10. It must be remembered that severe hæmorrhage, as in case 12, leads to intense vasoconstriction and will influence the recovery of the ischæmic limb. The involvement of the thumb shows that, despite the ulnar-artery puncture, the thiopentone was widely distributed. There is the less likely alternative explanation that, if the brachial-vessel division was very low, some of the thiopentone may have been injected in retrograde manner into the brachial artery and then distributed via the radial artery.

Other Cases.—I have had personal communications from at least six other anæsthetists who believe that they have injected 5% thiopentone intra-arterially with no subsequent effect except for a flushing of the limb. I have seen one case after such injection and noted the flushing of the limb and that there was not the slightest sign of extravasation of blood to suggest that the artery had been punctured. This patient had a particularly mobile elbow, and on hyperextension the brachial artery came well forward, was tightly stretched, and invited injection. Lundy (1942) has reported the intra-arterial injection of 8 ml. of $2^1/_2$% thiopentone in 2 cases, with no untoward effect. Adams (1944) reports injection of 5 ml. of 10% thiopentone with no near or remote effect, which is indeed surprising. Lees (1943) has reported a case where, after an injection of 5% thiopentone there followed burning pain and a spreading red flush down the forearm; he felt sure that the injection was "intravenous," but the story is typical of intra-arterial injection.

(To be concluded)

TRANSORBITAL LEUCOTOMY*

WALTER FREEMAN
M.D., Ph.D. Washington, D.C.

From the Department of Neurology and Neurological Surgery, George Washington University School of Medicine

LESS than a year after the introduction of leucotomy by Moniz (1936), Fiamberti (1937) proposed a simplified operation, which later he carried out, on the frontal lobes by way of the orbital plate. This route had been used before for certain intracranial procedures such as ventricular puncture (Dogliotti) and intracerebral malaria inoculation (Ducosté) with ease and safety. Fiamberti insisted on these aspects, but did not compare the effectiveness of the method with that of other types of leucotomy. Then the war prevented further communications, and only in 1947 did Fiamberti's work again come to notice outside Italy. The results were still not very substantial, and the papers by Fiamberti (1947), Ali (1941), and Ferraro (1942) gave no clear idea of the virtues of this approach, merely denying its vices. In justifying his novel approach Fiamberti stated: "In the present state of affairs, if some are critical about the lack of caution in therapy, it is, on the other hand, deplorable and inexcusable to remain apathetic, with folded hands, content with learned lucubrations upon symptomatologic minutiæ or upon psychopathic curiosities, or, even worse, not even doing that." In a recent personal communication Fiamberti writes that he has performed about 100 of these operations without mishap, but he is still indefinite about the results.

Two important pieces of research, the results of which have not yet been published, call attention to the possibilities of transorbital leucotomy as a valuable addition to the therapeutic armamentarium of the

was being poured on it, and flames shooting from ends of fingers."

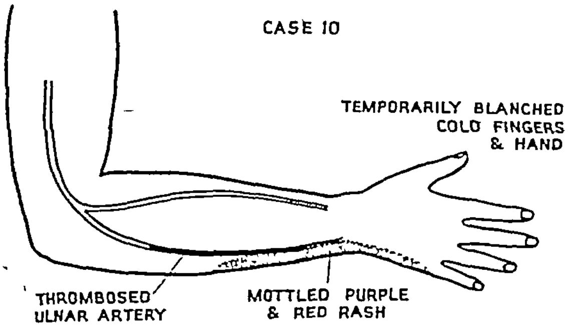
Injection stopped and "vessel" found swollen to size of a lead pencil, hard, and pulseless for about 4 in. distally —i.e., in its superficial course. Patient went grey and started sweating; about 45 sec. later lost consciousness. Anæsthesia continued with nitrous oxide and oxygen.

Some 5 min. later, ulnar three fingers and hypothenar eminence cold and blanched. This lasted $^1/_2$–$^3/_4$ hour; 15 min. after injection, mottled purple and red purpuric rash developed on lower part of ulnar aspect of forearm, and spread to hypothenar eminence. This lasted about five days.

After operation patient woke with very severe pain in hands; morphine necessary. Next morning moderate œdema of whole hand and wrist. Artery hard, but not so swollen as immediately after injection.

Ten days later, patient symptomless but remained with a thrombosed aberrant ulnar artery. Similar aberrant vessel on opposite arm (see fig. 18).

The ultimate effect of this injection of 10% thiopentone was indeed fortunate; some gangrene of the fingers at least was to be expected. An immediate thrombosis appears to have followed the injection, and this was also observed in Van der Post's (1942) case (case 12). Serious sequelæ are less likely after puncture of an aberrant ulnar artery (see anatomical explanation below). The vessel in case 10 pursued a subcutaneous course and pierced the deep fascia in the distal part of the forearm.



CASE 10
TEMPORARILY BLANCHED COLD FINGERS & HAND
THROMBOSED ULNAR ARTERY
MOTTLED PURPLE & RED RASH

Fig. 18.

The blanching of the fingers, lasting only $^1/_2$–$^3/_4$ must imply that there was only temporary spasm of vessels. The character of the pain indicates that injection was certainly intra-arterial, and the fact all the finger-tips were affected indicates a fairly distribution of the thiopentone. Why there were no effects I cannot explain.

Case 11.—This case has also been reported by Macint and Heyworth (1943).

A boy, aged 5 years, was given 1·5 ml. of 10% thiopento as induction before tonsillectomy. An hour later, ch complained of severe pain in hand and distal part forearm, which was blanched from elbow downwards about an hour colour returned, pain appeared to pass off, a child went to sleep. Discharged from hospital two days lat

Readmitted a week later because of sudden severe p in forearm. According to parents, child had continued complain of pain in right arm from date of discharge; p prevented him from sleeping. As time went on, pain wrist seemed to increase, and a blue mark in middle of rig elbow and several black marks on ulnar aspect of forea were noted.

Hand and arm were warm and of good colour. Chi kept forearm and wrist bent and could not move the Three days later, hand had improved; child managed turn over leaves of his book but could not hold anything right hand. Five days after injection, child appeared to free from pain, played, and moved his hand.

On *eighth day* he complained that arm was again painf and stiff. He went out to play but came back screaming w pain; hand white, nails blue.

In hospital, hand was ischæmic, cold, with blue nai Forearm was held in semi-flexion, and wrist in palmar flex fingers were tender on attempting dorsal flexion. Stro pulsation could be felt in brachial artery up to middle of elbo where it suddenly ceased. No radial pulse. Hand was an thetic as far as middle of hand, though such sensation cou not be determined accurately in a child. There were a fe

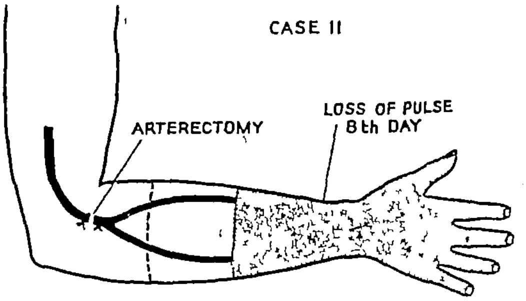


Fig. 19—Broken line indicates site of amputation.

bluish spots in middle of forearm, and there was a da area over injection site.

Observation continued for two days, during which the appeared to be recurrent spasms of pain in wrist. No mov ment was possible in fingers, hand remained cold, and senso loss appeared to be extending upwards.

Ten days after original injection, elbow was explore Brachial artery was pulsating throughout antecubital fos but no pulsation could be seen in its divisions. Radial arte was so blue that it was first mistaken for venæ comites. Aft a temporary clamp had been placed on brachial arter radial artery was divided 0·5 cm. from its origin. Lumen w found filled with old dark blood-clot, which appeared extend entire visible distance of radial artery—4 cm. O removal of clot from proximal end, vessel began to ble slowly, and this end was therefore ligated. Entire brachia vessel division was now exposed; ulnar artery was swolle glossy, and soft, with doubtful pulsation. Brachial arte appeared swollen ("abnormal bulge") in terminal 1·5 cm and it was decided to resect this section of brachial arter up to its bifurcations. Heparin injected into ulnar an radial arteries, but very little flowed down. Finally enti visible length of radial artery, which contained clot througho was resected. Portion of radial artery which was handle was smaller than unhandled portion, even though clot extende throughout.

ll three patients recovered and went home, but their efulness is limited.

RESULTS

General and undesirable changes in personality after ansorbital leucotomy are usually minimal. Only casionally is there a certain indolence and tactlessness. r the most part the patients are quite themselves, the ly thing lacking being a certain subtlety and a modicum insight into their own mental mechanisms. Personality s by Dr. Mary Frances Robinson have revealed rich- as well as depth in patients who have been operated y the transorbital route.

eturn to effective existence may also be rapid. Some ents who have been under maintenance shock- apy on an ambulatory basis have left the hospital the day following operation and have been back heir household tasks within a week. Others have rned to their positions as soon as their black eyes e cleared. Three patients have been married since ration and are reported to be carrying on normally.

esponse to operation is of course variable, depending part on the previous personality and the type and erity of the illness. Sometimes there is a spectacular ponse; more often there is a period of elation followed a return of symptoms and then slower and more ady improvement. Sometimes patients only maintain se improvements for a period and then relapse. The st patients, especially among schizophrenics, show le change, but they may be benefited later by major ntal leucotomy. Transorbital leucotomy can render tients more responsive to other forms of treatment, rticularly electro-shock therapy. Perhaps the greatest nge observed in patients is their increased friend- ss and sociability when their emotional tensions ve been lifted. Thus effective psychotherapy may come possible for the first time.

Certain symptoms of mental illness are helped, and hers not. Anxiety and emotional tension, for instance, e often overcome; depressive ideas, phobias, and essional thoughts usually improve. Fixed delusions d hallucinations are rather resistant, and motor mpulsions or tics may continue relatively unchanged. operation is performed before the psychosis or urosis becomes fixed, however, even the most ominous mptoms may subside within a few days.

INDICATIONS AND CONTRA-INDICATIONS

Transorbital leucotomy perhaps finds its most success- application in certain patients who improve and then apse or who are being carried on maintenance shock- erapy. This applies particularly to schizophrenics who ve been in hospital for many months and have not covered with shock but are not yet too emotionally teriorated to benefit from leucotomy. Patients with pression of middle and later life, particularly the xious types, may do well with transorbital leucotomy ter the failure of shock therapy. Obsessionals and tients with anxiety states, hypochondriasis, and ychosomatic conditions have been helped within the neral limitations reported above. Thus far, patients th intractable pain of long duration have not responded well as to major leucotomy (Freeman and Watts 46). Schizophrenic psychosis of long duration is nerally a contra-indication, though reports from rtain hospitals indicate that disturbed behaviour may brought at least partly under control. Severe otional dilapidation is the outstanding contra- lication to leucotomy of any type, and can certainly t be overcome by the transorbital operation. We have t yet had any experience of its use among alcoholics, g addicts, or criminals.

Transorbital leucotomy has proved valuable in mental spitals where specialised neurosurgical techniques are rarely available. It is also applicable in patients who are not recovering but nevertheless do not seem to be sick enough to require major leucotomy. The operation can be performed by the psychiatrist as soon as he has familiarised himself with the landmarks and practised on the cadaver. It requires little more preparation of the patient than is demanded for electro-shock therapy; the operation is brief, safe and simple. Even the route of approach to the brain requires no preparation, since the conjunctival sac is normally sterile and a copious flow of tears is promoted by the electric current. No complications due to infection have been reported, but sulphadiazine 4 g. in divided doses is given as a routine after operation.

At the Washington meeting of the American Psychiatric Association on May 19, 1948, where this work was first reported in the U.S.A., speakers from half a dozen different hospitals emphasised the safety and effectiveness of transorbital leucotomy. One-third of the schizophrenics and more than half the involutionals treated had been discharged. Further follow-up studies and work will be needed to determine the lasting value of the method and to learn more about its indications and contra-indications compared with major lobotomy; but it seems promising at present.

SUMMARY

Frontal leucotomy can be performed safely and effectively by the transorbital route of Fiamberti during the phase of coma following electro-shock.

Recovery may be very rapid and undesirable changes in personality are minimal.

The operation is a minor one and may be performed by the psychiatrist provided he has thoroughly familiarised himself with the technique and landmarks through previous practice on the cadaver.

The operation has been most effective in certain patients where tension was a prominent feature of the illness and who were beginning to become chronic in spite of more conservative therapies.

I wish to acknowledge the assistance of my widely scattered colleagues: Drs. Haas and Williams, of Yankton, South Dakota; Drs. Keller, C. H. Jones, and J. G. Shanklin, of Fort Steilacoom, Washington; Dr. R. B. Toller, of Stockton, Calif.; Dr. E. H. Reaser, of Huntington, West Virginia; and Dr. Joseph Knapp, of Weston, West Virginia.

"... The world of the future—if any world survives—will be a world of diversity, held together by a conception of common interests. It will be a world in which many political faiths and economic creeds are tolerated and widely differing points of view fertilise each other for the common good. Our challenge in this generation is to discover the common interests, the terrain of possible collaboration, the overlapping areas of curiosity and sympathy, of aspiration and mutual advantage, that bind the human race together regardless of ideologies or boundary lines. The search for these rallying points of unity, the development of new techniques and areas of coöperative action where ideas and experience can be pooled and combined—this is the immediate task; this comes first; this is the foundation of the ultimate structure of a united society.... In spite of all evidence to the contrary the things that divide the world are trivial as compared with the things that unite it. The mutualities of human beings everywhere far exceed their divergencies."—Dr. RAYMOND B. FOSDICK in the *Rockefeller Foundation Review* for 1947.

psychiatrist. One of these, by the Columbia-Greystone associates, reported at the New York Academy of Medicine in April, 1948, indicated that the favourable results obtained with frontal leucotomy may be duplicated by excision of the cortex covering the frontal poles of the brain, and in particular those parts termed areas 9 and 10 on the Brodmann chart. Furthermore, the investigators claimed that the changes in personality following "topectomy" are much less severe than those following leucotomy. The series of cases is rather small (24) and the period of postoperative observation has been rather short for assessment of final results, but of the 11 carefully selected patients in whom areas 9 and 10 (and part of 46) were excised 10 were usefully occupied after discharge from hospital.

The other investigation, by Spiegel and Wycis and their collaborators, reported at the meeting of the American Neurological Association in June, 1948, involves a direct attack on the medial nucleus of the thalamus with a stereotaxic instrument based upon the Horsley-Clarke apparatus. After the electrocoagulation of 3–5 minute areas in each medial thalamic nucleus patients are said to develop disorientation, incontinence, masking of the face, plateau speech, and abolition of the emotional component of the psychosis. Clinical improvement is comparable with that observed after leucotomy. This research bears out the theory of Freeman and Watts (1947) that the affective change in the patient is due not so much to interference with the cerebral cortex as to the retrograde atrophy that affects the thalamus once its connexions with the cortex have been severed. The topectomy investigation indicates that a more restricted operation on the frontal lobes may successfully relieve the patient without producing a serious change in personality.

Consequently, transorbital leucotomy, which undercuts areas 9 and 10, seems to be a valid procedure.

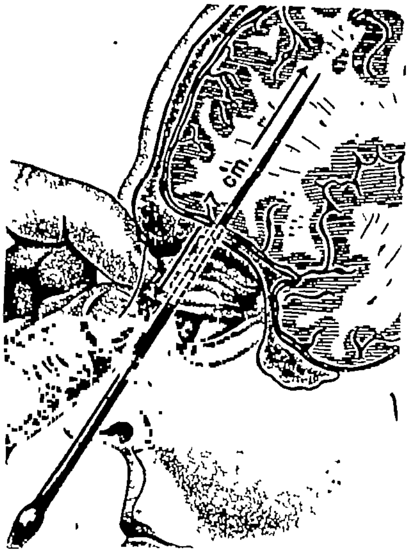
Our own studies on the cadaver in 1945 confirmed the fact that the orbital plate could be rather easily perforated without danger to structures within the orbit and without encountering large intracranial vessels; and that the thalamofrontal radiation could be severed fairly far anteriorly without disturbing the cortex except to a minimal degree.

Early in 1946 10 patients were subjected to transorbital leucotomy with encouraging results. Two years later (Freeman 1948) 6 of them were fully restored and only 1 was in hospital. The series has been extended since then to more than 100 cases, in collaboration with doctors in mental hospitals in South Dakota, West Virginia, California, and the State of Washington (Jones and Shanklin 1948). There have been no deaths.

TECHNIQUE

We have found that transorbital leucotomy can be performed satisfactorily in the postconvulsive phase of electro-shock. Electro-shock appears to have a generally disrupting effect on cortical activity, temporarily abolishing the psychotic manifestations and bringing the patient into a brief period of increased adaptability. When leucotomy is also performed, the effects of the electro-shock seem to be at least protracted, and often permanent. A few operations under ordinary anæsthesia have been performed by others, however, and equivalent results are reported. Nevertheless, electro-shock requires so little preparation and is so familiar to the psychiatrist that it seems to be the method of choice.

To maintain the patient in a somewhat prolonged phase of coma, two convulsive doses of electricity are given, the second about one or two minutes after the first convulsion has subsided. After the second convulsion a towel is placed over the patient's nose and mouth to prevent contamination by saliva and nasal secretions. The upper eyelid of the patient is pinched between t and finger, bringing it away from the eyeball. point of the transorbital leucotome is then introd into the conjunctival sac and moved around agains roof of the orbit until the top of the vault is encount The leucotome is brought parallel with the bony of the nose, and its base is tapped lightly with a ha to drive it through the orbital plate. To aim the l tome properly the shaft must press rather strongl the eyeball, but no harm to the globe has been except for occasional subscleral hæmorrhage.



Transorbital leucotomy.

The transorbital leucotome† consists of a tool shaft 12 cm. long and 4 mm. in diameter, tapering fo last 6 cm. rather fine with a slight Its handle is long and 8 m diameter equipped wi cross-arm a base. The is graduate centimetr double line marked at 7 which is the frequently point.

When the cotome reached the level, its is pushed lat as far as the gins of the will permit sever the fib the lower po of the thalamofrontal radiation. It is again return mid-position and gently driven to a depth of 7 cm. al in the plane of the bony ridge of the nose (see figure) this depth it is possible, by swinging too far, to la arteries in the depth of fissures on either the m or the lateral surface of the frontal lobe; and, sinc thalamofrontal radiation is a rather narrow band i region, a movement of only 15–20° laterally and med is sufficient. When the sweeps of the instrument h been made, it is withdrawn, and moderate pressu maintained over the eyelids for several minute prevent excessive bleeding into the orbit.

Unless the patient is still deeply unconscious, additional electroconvulsive shock should be administ before the other side is operated on. Patients seem tolerate multiple convulsions quite well. In view of refractory period, it is usually necessary to increase time of passage of the electric current by repea tripping of the switch until the convulsive thresho reached. No complications have been encountered doing this. After the convulsion has subsided, the ot side is operated on in the same way.

Recovery from transorbital leucotomy can be rapid. Sometimes within an hour the patient may awake and talking. Headache is usually present, occasionally nausea; incontinence is rare. Swelling the eyelids is common but tends to clear in a day or t Ecchymosis is often encountered, and the discolorat may persist for two weeks. The swelling is probably to the escape of cerebrospinal fluid through the orb plate. Rhinorrhœa has not been observed. Complicati have developed in only 3 of more than 100 operati In all of these there was bleeding, with very severe in and paralysis in one, and mild hemiparesis in the oth three patients recovered and went home, but their fulness is limited.

RESULTS

General and undesirable changes in personality after nsorbital leucotomy are usually minimal. Only asionally is there a certain indolence and tactlessness. r the most part the patients are quite themselves, the ly thing lacking being a certain subtlety and a modicum insight into their own mental mechanisms. Personality ts by Dr. Mary Frances Robinson have revealed rich- s as well as depth in patients who have been operated by the transorbital route.

Return to effective existence may also be rapid. Some ients who have been under maintenance shock- rapy on an ambulatory basis have left the hospital the day following operation and have been back their household tasks within a week. Others have urned to their positions as soon as their black eyes re cleared. Three patients have been married since ration and are reported to be carrying on normally.

Response to operation is of course variable, depending part on the previous personality and the type and erity of the illness. Sometimes there is a spectacular ponse; more often there is a period of elation followed a return of symptoms and then slower and more dy improvement. Sometimes patients only maintain se improvements for a period and then relapse. The st patients, especially among schizophrenics, show le change, but they may be benefited later by major ntal leucotomy. Transorbital leucotomy can render ients more responsive to other forms of treatment, ticularly electro-shock therapy. Perhaps the greatest nge observed in patients is their increased friend- ss and sociability when their emotional tensions e been lifted. Thus effective psychotherapy may ome possible for the first time.

Certain symptoms of mental illness are helped, and ers not. Anxiety and emotional tension, for instance, often overcome; depressive ideas, phobias, and essional thoughts usually improve. Fixed delusions d hallucinations are rather resistant, and motor mpulsions or tics may continue relatively unchanged. operation is performed before the psychosis or urosis becomes fixed, however, even the most ominous mptoms may subside within a few days.

INDICATIONS AND CONTRA-INDICATIONS

Transorbital leucotomy perhaps finds its most success- application in certain patients who improve and then apse or who are being carried on maintenance shock- erapy. This applies particularly to schizophrenics who ve been in hospital for many months and have not covered with shock but are not yet too emotionally teriorated to benefit from leucotomy. Patients with pression of middle and later life, particularly the xious types, may do well with transorbital leucotomy ter the failure of shock therapy. INCONTINENCE OF URINE IN THE AGED

THOMAS S. WILSON
M.D. Belf.
GERIATRICIAN, CORNWALL COUNTY COUNCIL

INCONTINENCE of urine has long been recognised as particularly likely to occur at either extremity of life. Allen (1733), quoting the "Sentiments of Ettmüller—Of an Incontinency of Urine," states:

> "The Cause of an involuntary discharge of Urine, is a Deficiency in the Constriction of the Sphincter of the Bladder, by a Palsy, Contusion, by staying too long in cold Water, by a difficult Labour, and sometimes it happens to Women in the last months of their going with Child. . . . Children and Old People are the common Pissers-a-bed, but these come not to the Physician for Cure."

Allen does not give the reason for this attitude of therapeutic negativism, though he later says: "in old Persons it is altogether incurable, unless hot Baths relieve them."

Though in recent years a considerable amount of attention has been devoted by medical writers to the ætiology and treatment in children of a persistent inability to control bladder function, a similar disability in the aged has tended to be ignored by them, and in practice has almost invariably been regarded with a singular fatalism.

Sphincteric weakness resulting from senile muscular atrophy has persisted to be the common explanation of the condition advanced by most modern writers, but little or no evidence has been produced in support of this assumption. Langworthy et al. (1937), on the other hand, after studying aged incontinent patients, concluded that injury to the central nervous system was the most frequent cause of the disability, and Geist and Salmon (1943) relate the incontinence of some postmenopausal women to a senile vaginitis and œstrogen deficiency.

MECHANISM OF MICTURITION

The neurophysiology of the bladder and its sphincters has been described by so many workers that I do not propose to discuss in detail the mechanism of normal micturition. This has been admirably summarised by Denny-Brown and Robertson (1933) as follows:

> "The process of storage of urine and its evacuation occurs in a reservoir of which the distension excites a tendency to an automatic discharge.
>
> "The primary factor in discharge is contraction of the wall of the bladder with an accompanying secondary reciprocal relaxation of both sphincters.
>
> "Control of discharge and utilisation of the reservoir above about 50 c.cm. depends upon conscious and unconscious inhibition of vesical contraction. If necessary this may be reinforced by active voluntary excitation of the external sphincter until vesical contraction is overcome.
>
> "More usually the process pursues a course of progressive complete adaptation without the occurrence of sufficiently powerful vesical contractions to be accompanied by full relaxation of the internal sphincter until conscious or unconscious control of vesical contraction is released by voluntary effort."

The afferent and efferent arms of the reflex arc concerned in bladder contraction lie in the pelvic parasympathetic nerves, and the arc is completed in the 2nd, 3rd, and 4th sacral segments of the cord. Cortical control of the bladder, which is absent in the young infant but is normally acquired during the first few years of life, is exercised by means of inhibitory impulses transmitted from the cortex to the sacral region by spinal pathways situated in the dorsal halves of the lateral columns (McLellan 1939).

INCIDENCE OF URINARY DYSFUNCTION

Some degree of urinary dysfunction in the aged is so common that it has come to be regarded as almost normal. Of 35 male and 33 female chronic sick pa over the age of 70, only 5 and 9 respectively were from urinary complaints. In both sexes the commo symptom was increased frequency of micturition, most of the patients also complained of precipitate, imperative, micturition. The findings were as follow

Sex	*No. of patients*	*Diffi-culty*	*Slow-ness*	*Preci-pitancy*	*Fre-quency*	*Incon-tinence*	*Noc-*
Male ..	35	3	7	19	22	11	[illegible]
Female ..	33	8	11	17	23	14	[illegible]
Totals ..	68	11	18	36	45	25	[illegible]

Many of the patients who complained of slownes difficulty in initiating micturition related this sympt to nervousness or emotional upsets, and in several c the information was volunteered that voiding facilitated by hearing the sound of running water.

INVESTIGATION OF URINARY FUNCTION

For this investigation 36 aged males and female the chronic sick wards were selected at random. of the patients investigated had some urinary dysfunc 21 being incontinent, but some who did not complain urinary symptoms were included in the series as contr At the outset of the investigation, or shortly befor began, most of the 36 patients were bedridden, but of them were mobilised, at least to the extent of able to sit by their bedside, some being re-educated walking-machines.

In each case the reaction of the bladder in respo to gradual distension with fluid was determined wi simple cystometer (fig. 1). A 1 in 10,000 solution potassium permanganate was warmed to about b temperature and allowed to enter the bladder at the r of about 10 ml. a minute. Serial readings of bladd pressure recorded on the manometer were chart graphically against the volume of fluid instilled.

Technique

Before cystometric examination the patients were instruc to cough, and the presence of any stress incontinence noted. They were then told to pass urine, after which t were placed on the couch, the females in the lithot position, and a catheter was passed with strict aseptic cautions, the residual urine being withdrawn and meas The ease or otherwise with which a catheter was passed some indication of the degree of obstruction to the ve outlet. At this stage the state of the vagina and ure orifice could conveniently be observed, and the presen cystocele, retocele, or senile vaginitis noted. In many c a smear was made from the vaginal mucosa to determine state of the epithelial cells.

The apparatus shown in fig. 1 was next connected to catheter, the zero mark on the manometer having b

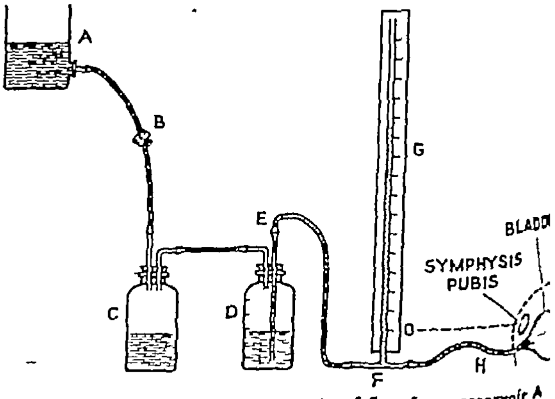

Fig. 1—Apparatus for cystometry: rate of flow from reservoir A bottle C is controlled by screw-clip B; fluid entering bottle C places air, which in turn displaces potassium-permanganate sol from graduated bottle D past one-way valve E to T-junction F thence via catheter H into urinary bladder. A rate of flow drops a minute into C gives a rate of flow of 10 ml. a minute bladder.

adjusted to the same level as the symphysis pubis, and the pressure in the system being zero. The screw-clip B was adjusted so that fluid was entering the bladder at about 10 ml. a minute, and throughout the examination the screw-clip was regulated so that this rate of flow was kept constant. The one-way valve E ensured that during contractions the fluid was not forced back into bottle D.

During the examination the patient was questioned periodically about the presence of bladder sensations, and was instructed to hold his water, especially when a rise in pressure indicated a bladder contraction. That the patient was in reality attempting actively to inhibit bladder contractions could be determined by observing the voluntary musculature of the perineum for the presence of contraction, which is associated with such an inhibiting attempt.

The amount of solution instilled into the bladder did not exceed 400 ml. If, however, distension became painful before this amount was instilled, the instillation was discontinued. If no reflex bladder contraction had taken place during the period of filling, the patient was instructed to attempt to void before the apparatus was disconnected.

The apparatus was next disconnected from the catheter, and the bladder emptied. It is important that the bladder should be emptied, if possible, during an active vesical contraction, rather than passively drained through the catheter.

Besides cystometric examination, a standard clinical examination was carried out on each patient, with special reference to the presence of lesions of the central nervous system, urinary infections, senile vaginitis, prostatic enlargement, and local abnormalities of the bladder outlet. There were no facilities for cystoscopy and a more detailed knowledge of the state of the bladder than that afforded by routine methods was unobtainable. As already stated, any obstruction to the bladder outlet was indicated by difficulty in passing the catheter, though of course this is not an invariable criterion of obstruction. Patients with gross structural abnormality of the bladder or of its outlet were not included in the investigation. Of the 36 patients examined only 2 were thus excluded—*a leaking suprapubic fistula being present* in one case, and a complete procidentia in the other.

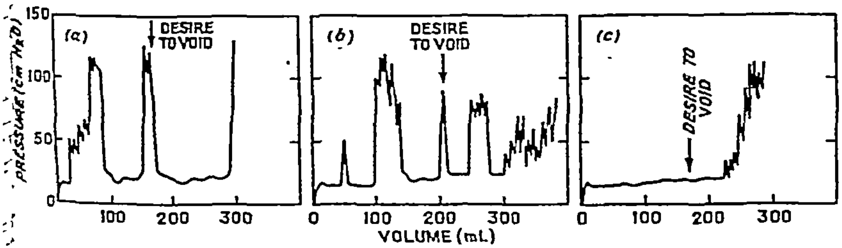

Fig. 2—Vesical pressure in a man, aged 71, who had increased frequency and precipitancy of micturition of several years' duration and was often incontinent: (a) at first cystometry; (b) a week later, showing improvement; (c) six weeks later, when symptoms had disappeared and patient said his urinary control was better than it had been for years.

RESULTS

On the entry of fluid into the bladder the pressure rose rapidly until the basic bladder tonus was reached. This reading varied from 8 to 18 cm. H_2O in different patients. Thereafter, unless bladder contractions took place, the curve of serial pressure readings ascended gradually until the instillation was discontinued.

In all the incontinent cases a point was reached at which the bladder did not accommodate further, and a sudden sharp rise in manometric pressure indicated contraction of the detrusor muscle. In spite of voluntary attempts to do so, the patients could not control the contractions, which were usually of considerable amplitude—as much as 125 cm. H_2O in some cases. These uninhibited contractions usually appeared early in filling, especially in the constantly incontinent cases, and almost invariably were not preceded by any sensation of desire to void. A typical vesical-pressure graph of such a case is shown in fig. 2*a*. Vigorous bladder contractions such as these, arising unheralded during physiological filling of the bladder, would undoubtedly *lead to involuntary emptying of the viscus.*

In the case of 3 constantly incontinent patients, however, in contrast with those already described, there was evidence of a moderate degree of adaptation of the bladder to distension, and contractions did not appear till comparatively late in filling. These patients were, however, completely confused and relatively inaccessible mentally, and it was evident in each case that the patient was not trying actively to control the bladder contraction. On the contrary, in 2 of the cases contraction of the abdominal musculature and relaxation of the perineum indicated a voluntary attempt to void. In these patients the incontinence was not a true dysfunction of the bladder mechanism, but rather a disorder of behaviour in which the patients voided urine (and often fæces) without reference to their surroundings, as the result of a dementia.

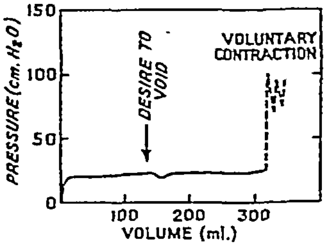

Fig. 3—Vesical pressure in a woman, aged 83, with no urinary complaint: bladder shows complete adaptation to instillation without uninhibited contractions.

Those patients in whom precipitate and overfrequent *micturition* was the main complaint, and in whom incontinence was only occasional, exhibited less bladder overactivity than did the constantly incontinent. Uninhibited contractions tended to arise later in filling, and there was occasionally prior, though admittedly short, warning of impending bladder contractions.

In patients who were free from urinary complaints the bladder either adapted completely during the instillation without contractions, or if contractions arose they were late in filling and were preceded at a considerable interval by increasing desire to void (fig. 3).

Most of the patients with precipitancy and incontinence noted an improvement in symptoms, occasionally dramatic, after cystometric examination. Frequency was less, and they had more control and could refrain from voiding for a longer time than before. In 10 of the 23 patients who complained of precipitancy or of incontinence the symptoms much improved or entirely cleared, and in 5 others some improvement was noted. Included in the 8 cases in which no improvement took place were the 3 patients whose incontinence was a disorder of behaviour rather than a dysfunction of the bladder mechanism.

Concurrently with the improvement in bladder function, cystometric evidence of increased bladder adaptation was observed. Uninhibited contractions arose later in filling than before and, where the incontinence had cleared, these contractions did not appear until an appreciable interval after the sensation of desire to void had been felt. Thus the patient had adequate warning of the state of bladder distension and could void *voluntarily before the* bladder was emptied reflexly (fig. 2).

The uninhibited contractions in some incontinent patients, more especially if the symptoms were long-standing, were poorly sustained and, though of normal amplitude, tended to subside rapidly. In these cases it was generally found that the bladder contained a consider-

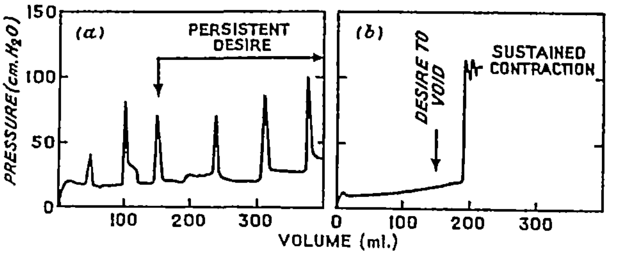

Fig. 4—Vesical pressure in a man aged 93: (a) while constantly incontinent, with residual urine 400 ml.; (b) a month later, when no longer incontinent, though micturition was still somewhat precipitate, and residual urine had decreased to 50 ml.

able quantity of residual urine. As bladder function improved with treatment, however, and overactivity was lessened, the contractions became more sustained and the quantity of residual urine decreased (fig. 4).

DISCUSSION OF RESULTS

The cause of incontinence of urine and, in a lesser degree, of precipitancy and urgency of micturition in the old people investigated was an overactivity of the reflex bladder mechanism in most cases.

A contributory factor to incontinence was, in some instances, a diminution of the visceral sensation of desire to void, with the result that the patient had little knowledge of the state of fullness of his bladder, or of the imminence of reflex voiding contractions.

In a few cases uncontrolled voiding resulted almost entirely from mental disorientation, and in only 3 cases did weakness or laxity of the vesical sphincter play an important part. In 2 of these patients there was a history of obstetric trauma, but the most patulous sphincter was detected in a nulliparous female with a hemiplegia.

Overactivity of the bladder mechanism resulted from a deterioration of the cortical inhibitory function, and from the presence of any local pathological state of the bladder of its outlet which tended to increase the excitability of the stretch receptors in the bladder wall. Of these two factors the former is the more important. In common with other cortical functions, it is not unreasonable to presume that inhibition of bladder activity participates in the general deterioration of efficiency which is a feature of senile involution within the nervous system. The actual cerebral lesion may be obscure. Neuronal atrophy, gliosis, and amorphous deposits have been described as occurring in the senile brain, and areas of softening, lacunæ of degeneration, small hæmorrhagic foci, and disseminated areas of atrophy often result from cerebral vascular disease (Critchley 1931). Commonly incontinence may be ushered in by a frank cerebral vascular lesion, often leading to hemiplegia.

Besides the deterioration of cortical inhibition resulting from structural damage to the nervous system there may also be a purely functional loss of inhibition. After a cerebral vascular lesion, injury to many of the nervous elements is transitory, and after a time recovery, or partial recovery, will ensue. Though the damage may not have been permanent, however, recovery of the function with which these elements were concerned may not take place until the patient has been re-educated in that particular function. Thus, as the recovering hemiparetic has to learn again the proper control of his limbs in walking, so, if the bladder inhibitory function has been in abeyance, control of bladder contractions must once again be acquired, as it was in infancy. Mitigating against the recovery of bladder control perhaps more than any other single factor is the semisomnolent state into which the aged patient so rapidly declines when confined to bed. In this vegetative existence the inhibitory function becomes involved in the general sluggishness of response to stimuli which is so apparent. In the present series the patients who were bedfast showed a much greater tendency to relapse after treatment.

Toxæmia and cerebral anoxæmia due to any cause, such as congestive heart-failure and severe anæmia, also tend to impair the inhibitory function, and thus lead to overactivity of the bladder.

Of the local pathological conditions a urinary infection is the most commonly detected. The incidence was high (50% of cases) and was relatively greater in females than in males. In some instances an acute urinary infection brought on precipitancy and incontinence, but in others chronic infections were found without an urinary dysfunction whatsoever. Infection was almo invariably present in the incontinent females, probabl as a result rather than the cause, of the incontinence. Urination often improved in spite of the persistence of a chronic infection. A chronic urinary infection therefore does not appear greatly to increase th excitability of the bladder reflex. If the infection i acute, however, reflex excitability is much increased. Geist and Salmon (1943) have related the urinary incontinence of some postmenopausal women to a senile vaginitis and œstrogen deficiency causing impaired tonus of the vesical sphincter. Many of the female patients in this series had a senile vaginitis, which was in some cases improved by the administration of stilbœstrol. There was improvement in urination, with less reflex bladder excitability, after œstrogen therapy in these cases, but results were not dramatic, and no change was observed in the tone of the sphincters. It i considered, however, that a senile vaginitis helps t increase the excitability of the bladder reflex.

The incidence of enlarged prostate was no greater among the incontinent patients than among the continent. The rôle of prostatic enlargement in urinary dysfunctions is discussed below.

RATIONALE OF TREATMENT OF OVERACTIVE BLADDER

Maclachlan (1863), discussing the treatment of incontinence in the aged, stated:

> "Injections of cold water, perseveringly applied, the urine being first drawn off, are said to have been successful in numerous instances."

Braithwaite (1944) has noted dramatic relief following the graduated distension of the bladder with warm boracic solution in severe diurnal frequency in children which has not responded to ordinary measures. In the present series both subjective and cystometric improvement in bladder function resulted, in many cases, from the procedures comprising cystometric examination. The reasons for this are twofold, of which the first is considered the more important:

(1) During the filling of the bladder the patient is constantly urged to inhibit contractions. If a contraction takes place,

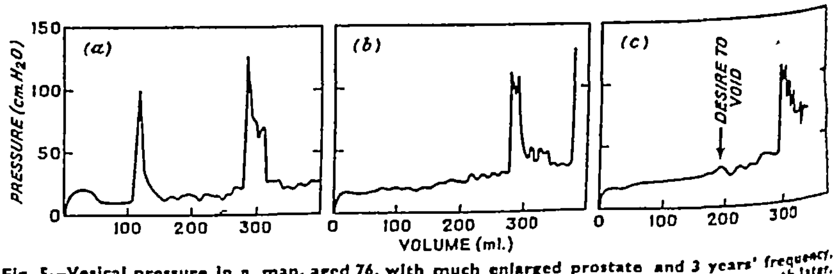

Fig. 5—Vesical pressure in a man, aged 76, with much enlarged prostate and 3 years' frequency, urgency, and incontinence, with residual urine 400 ml.: (a) at first cystometry; (b) a month later, when he had more control of micturition, though still occasionally incontinent, with residual urine 250 ml.; (c) two weeks later, when he had good control of micturition, with residual urine 80 ml.

here is no outlet for the fluid and the contraction registers is pressure on the manometer. Unless visceral sensation s much diminished, during such a contraction considerable liscomfort is felt by the patient. This discomfort can be elieved only by *inhibition of the contraction, and the patient* s thus stimulated to inhibit strongly. In this way, if the nhibitory pathways are intact, the patient is re-educated n the inhibitory function.

(2) In some instances where the bladder has been emptying eflexly in response to the addition of small amounts of urine he fibres of the bladder wall have become shortened and the ladder has become small and contracted. In these cases radual dilatation of the bladder with fluid will allow the uscles of the bladder wall to be stretched to an extent yond the normal. This will decrease the sensitivity of the retch receptors of the bladder wall, and may be regarded a parallel to the full mobilisation of a limb which has veloped a contracture. More usually, however, the inhibited contractions of the incontinent patient only rtially empty the bladder, and there is a gradual build-up increments of residual urine. This build-up is assisted y the erroneous impression so often entertained by nurses at a patient who has just been incontinent does not require bedpan or a bottle, and by the fact that the patient does not alise that his bladder has not been emptied. *It is necessary* ensure that when voiding does take place it is as complete s possible. Such patients must be encouraged to empty heir bladders voluntarily, even though they have only ecently been incontinent.

Attempts should be made to eradicate any local ondition which may cause bladder irritability. Finally, he patient should be stimulated to lead as active a nental and physical life as possible, and encouraged to ry and control bladder function.

PROSTATIC ENLARGEMENT IN RELATION TO URINARY DYSFUNCTION

Enlargement of the prostate is closely linked with urinary dysfunction in elderly males, and the term "prostatism" is commonly applied to such a syndrome in these patients. In the present series cystoscopic examination of the prostate was impossible, but some degree of obstruction was detected in as many patients without precipitancy or incontinence as it was in patients with these complaints. Where frequency and precipitancy of micturition were accompanied by enlargement of the prostate, these symptoms improved in most cases after cystometry, *and the efficiency of the urinary* mechanism increased, with reduction of residual urine (fig. 5).

In progressive enlargement of the prostate two factors come into play: (1) increasing obstruction to the vesical outlet; and (2) an increase in the irritability of the bladder. As a result of the obstruction, difficulty in initiating micturition and possibly dysuria arise, and later, if the obstruction increases, retention of urine develops. In response to the increasing obstruction, the bladder wall becomes hypertrophied and trabeculate. Increase in bladder irritability, if the cerebral inhibitory function is not impaired, gives rise to increasing frequency of desire to micturate. If, however, there is diminished cerebral control, as is so often the case in such patients, the increased bladder irritability is sufficient to cause the bladder reflex to break through the diminished cortical control, giving rise to uninhibited bladder contractions and urgent and precipitate micturition, perhaps with incontinence. As a result of the overactivity the bladder contractions are less efficient, and the amount of residual urine is increased. Thus the balance between the degree of obstruction to the vesical outlet and the efficiency of the neuromuscular mechanism of the bladder is of prime importance. In the presence of minimal prostatic obstruction large quantities of residual urine may be found as a result of inefficient bladder contractions (fig. 4).

Clarke (1937) has described cases of prostatic syndrome in which the symptoms disappeared spontaneously after cystoscopy. The amelioration of symptoms in many of these cases may have been due to improvement in vesical function following the instillation of fluid similar to that occasioned by cystometry.

In the investigation of cases of prostatic obstruction, therefore, it is considered that, besides estimating the degree of obstruction to the bladder outlet, the functional efficiency of the neuromuscular mechanism of the bladder must be assessed by cystometry, and if possible the function improved.

SUMMARY

The common urinary dysfunctions in the aged are increased frequency and precipitancy of micturition, often accompanied by incontinence.

The cause of these symptoms is mainly overactivity of the neuromuscular mechanism of the bladder. Sphincteric weakness is important in only a small minority of cases.

Overactivity of the bladder mechanism results from diminution of cortical control and from local irritative conditions of the bladder and its outlet. These factors operate to different extents in different cases but commonly the former plays the more active rôle.

Impaired cortical control may be due to structural changes within the nervous system and to a functional loss of inhibitory power. An impaired mental state is a contributory factor, as also is the confinement of the elderly patient to bed.

In many cases of overactivity of the reflex bladder mechanism function improves as a result of gradual distension of the bladder with fluid and inhibitory re-educative training.

The efficiency of the neuromuscular mechanism of the bladder is doubly important in prostatic enlargement. The routine investigation of the prostatic syndrome in the aged should include cystometry, so that the bladder function may be assessed and, if possible, improved.

". . . Few would deny the advantage of good build, fast and accurate neuromuscular coördination, strength, physical health and a high natural resistance to disease. We can surely encourage those endowed with such qualities to regard themselves as proper parents for the next generation. But in the field of temperament, our aims are much less clear. There is no such thing as a good and desirable type of temperament, and a bad and undesirable one. It takes all sorts to make a world. There is room for the quiet, the docile and the stable; but there is room also for the man of strong passions, for the natural born rebel, for the man whose moods take him from phases of elation and enhanced activity into troughs of depression. It is true, indeed, that a man like Hitler can cause much greater harm to humanity than even a million mental defectives; but we cannot say, if Hitler had had children, that they would have been any more likely to have been bad citizens than anyone else's. It is particular combinations of temperamental qualities which are productive of large effects, good or bad. Recombined in another way, the effect of the genes responsible would have been different. In fact we are too uncertain of where we want to go, and too ignorant of the foundations on which we stand, for there to be at present a practical eugenic approach to the betterment of human personality."

SPONTANEOUS RUPTURE OF THE RECTUM

REPORT OF A CASE

CHARLES P. ALLEN
M.B. Lpool, F.R.C.S.E.
LATE RESIDENT SURGICAL OFFICER, KING GEORGE HOSPITAL, ILFORD

TRAUMATIC rupture of the rectum appears to be fairly common, but not spontaneous rupture.

Lindenbaum [1] collected the records of 26 cases, including one reported in 1827 by Brodie, who apparently was the first to describe this condition. Of these 26 patients 24 died. In 23 cases rupture was associated with effort: 12 during defæcation, 4 during weight-lifting, and the remainder after a fall, while vomiting, during micturition, during childbirth, or during the return of the prolapsed rectum after purgation. In 13 cases rupture was associated with prolapse of the rectum, and in 2 with cancer. In 8 cases no pathological abnormality was found. Guibé [2] describes 1 case in which the rectum was ruptured during sleep.

The following case appears to be one of the rare spontaneous ruptures not associated with strain or any pathologic abnormality.

A male photographic process operator, aged 54, felt a sudden moderately severe pain in the lower part of his abdomen while walking to work after his midday meal.

The pain, at first felt chiefly in the hypogastrium, gradually spread over the whole abdomen, but he continued with his work until 4.15 P.M., when he was obliged to return home because of the severity of the pain. In response to a "feeling of fullness in the back passage" and a sensation that "something wanted to come away" he took a dose of Glauber's salt, which he immediately vomited.

He reached hospital via his doctor just before midnight and gave a history of many years' chronic constipation, but had for about six weeks not found it necessary to take purgatives. There was *no history of passing blood or mucus*; his bowels were opened naturally early that morning, and enemas were never used.

Examination revealed generalised abdominal rigidity and absence of abdominal breathing, with tenderness more acute in the right inguinal fossa and in the right epigastrium. Liver dullness and bowel sounds were absent. Rectal palpation revealed a walnut-sized swelling in the pouch of Douglas, with tenderness more acute on the left side. Anus of good tone and not patulous. Slight cough, and a few râles at both lung bases. Blood-pressure 160/80. Temperature 101·6°F, respiration 22 per min., pulse-rate 78.

Laparotomy.—About eleven hours after onset of symptoms his abdomen was opened through a right paramedian infra-umbilical incision. Peritoneal cavity contained purulent fluid. Appendix normal.

A mass of fæces about 1 in. in diameter and of the consistence of fresh putty was lying free in the pelvis, and a transverse tear 1½ in. long was found in the anterior wall of the first part of the rectum.

The slit in the mucosa was not indurated or friable, and there was no hæmorrhage. Rectum and pelvic colon otherwise normal. *No evidence of foreign body. Small intestine* had not prolapsed through tear.

Tear was sutured in two layers, and a suprapubic pelvic drain inserted. Operation completed by left inguinal colostomy.

Progress.—Postoperative treatment included sulphadiazine and penicillin. Patient made an uninterrupted recovery. Three months later colostomy was closed by intraperitoneal method.

I wish to thank Mr. Neil Sinclair, senior surgeon to King George Hospital, Ilford, for permission to publish this case.

CONGENITAL TORTICOLLIS IN IDENTICAL TWINS

A. E. STEVENS
M.B. Lond., F.R.C.S.E., D.T.M. & H.
ASSISTANT SURGEON, REDHILL COUNTY HOSPITAL, SURREY

THERE are many records of the same abnormality in identical twins, but none of torticollis.

The following two cases of torticollis were in identical twins born on July 5, 1935. Unfortunately no details of their obstetric history can be obtained, since they were born in a nursing-home which has since been closed, and their mother died three months after their birth. The aunt, who looks after them, does not know of any abnormality during labour. There is no history of torticollis or of hereditary disease in any other member of the family; and, apart from the fact that one child has strabismus, they had no other congenital abnormalities. The twins are otherwise healthy and normal.

They were admitted to the Redhill County Hospital on March 10, 1947, with an identical well-marked right torticollis. In both cases the clavicular head of the sternomastoid muscle was more contracted than the sternal head, and there was a small bony swelling at the insertion of the muscle into the clavicle. There was no sternomastoid "tumour." There was obvious right facial hemiatrophy and an early scoliosis of the upper dorsal and lower cervical spine. The physical defect was the same in the two cases.

As both twins had an eye defect, the question of ocular torticollis was considered, though they did not show all the features of this disease. They were therefore referred to Mr. G. J. Ahern, county ophthalmologist, who reported as follows:

"Twin no. 1 had a left convergent concomitant squint of 15°. There was no suggestion of a vertical deviation which goes with an ocular torticollis. I consider she has a straightforward left convergent concomitant squint due to difference in the refraction of the two eyes, and that her torticollis is incidental.

"There is no evidence of strabismus in twin no. 2. Her visual acuity is subnormal. There is nothing very strikingly similar in their eye defect. Lastly, the only similarity is in twin no. 1's left eye and twin no. 2's right; and, if this was playing any part in their torticollis, one would expect the head tilt on opposite sides."

At operation on March 11, the sternomastoid muscle and deep fascia were divided, after which the twins made a satisfactory recovery. When they were last seen on Aug. 18, neck movements were normal.

Many causes of congenital torticollis have been suggested, including heredity, ischæmia, and trauma. Mercer [1] states that trauma is generally held to be the primary cause. McMurray [2] gives the theory that the contracture of the sternomastoid is similar to that occurring in Volkmann's ischæmic contracture and is due to thrombosis of the end-artery which supplies the middle part of the sternomastoid muscle. There is no record of a sternomastoid swelling in these twins, and it must be assumed that the torticollis is congenital. Illingworth and Dick [3] consider that there is no single cause of congenital torticollis; that some cases must be attributed to developmental aplasia of the affected cervical segments; and that this is the usual cause. In these twins a traumatic origin can be virtually excluded, for it is most unlikely that they suffered precisely similar trauma. A congenital developmental error is the probable explanation.

I have to thank Mr. Norman Pitt, medical superintendent of Redhill County Hospital, for his interest and encouragement; and Mr. Ahern for his report on the eye condition.

Preliminary Communication

EXSANGUINO-TRANSFUSION IN ACUTE LEUKÆMIA

It is, of course, still true that no method of treatment will cure acute leukæmia, but that is no reason for complete inactivity on the part of the physician, because in many—perhaps most—cases, it is possible to induce a remission. Since nothing is known of the cause of leukæmia in man, treatment must necessarily be empirical; nevertheless, one's views on the cause of the disease may influence the choice of treatment. Those who hold that the leukæmic process is neoplastic will tend to favour radiotherapy, though in acute leukæmia it is worse than useless. If, on the analogy of avian leucoses, the disease is regarded as infective, the temptation is to try the various antibiotics. But holders of either of these theories are, not unnaturally, inclined to therapeutic nihilism, because there is no effective treatment for generalised malignant tumours or for the virus diseases.

On the whole, the consensus is in favour of the neoplastic theory, perhaps mainly because the cellular characters are reminiscent of those characteristic of malignancy. That is true enough, but similar cytological appearances are found in the immature red cells in pernicious anæmia, which is not neoplastic, though about 30 years ago there was a tendency among pathologists to think that it was.

Few, if any, writers have suggested that the cellular changes are secondary to abnormalities of the milieu interne—in other words, that the dedifferentiation or undifferentiation of the leukæmic cells follows changes in the blood-plasma. That this is a possibility is suggested by the observation of Schwind,[1] that injection of normal blood-plasma leads to diminution in the number of myeloblasts in the blood, which seems to indicate that the pathological process in the hæmopoietic tissues is not entirely autonomous. Then again, Israëls[2] found that, in tissue culture, leukæmic myeloblasts could mature into myelocytes—a clear indication that they are not totally disordered, but that their abnormalities depend on their environment. Another significant point is that Dreyfus,[3] after a careful and extensive study of the literature of remissions in acute leukæmia, has shown that there is a direct relation between the likelihood of a remission and the number of blood-transfusions and the total amount of blood infused.

Then came the remarkable reports of Bessis and Bernard,[4] who performed a replacement transfusion in a case of acute leukæmia and produced an immediate remission. Occasional injections of 100 ml. of blood, together with penicillin whenever sepsis occurred, prolonged the remission for months. I had the opportunity of seeing such a case in Paris. A man of 40 developed a remission of acute leukæmia after an exsanguino-transfusion and nine months later is still in fair health, though it has been necessary to give about 100 ml. of blood every fortnight and also short courses of urethane when the leucocytes rise unduly high. As Bessis will publish details of this case I cannot give more information about it, but I wish to call attention to some of the remarkable changes that followed replacement transfusion in the following case of acute leukæmia.

A woman, aged 34, had been diagnosed as suffering from acute leukæmia about two months before I saw her, and had been given about 4 pints of blood. Then, because it is impossible to obtain very large quantities of blood at any one time in England (a matter I hope to discuss in another article), the patient was taken to Paris, where Tzanck performed exsanguino-transfusion in two parts, with an interval of two days between.

The hæmogram, when the patient left London, was:

Red cells	2,600,000 per c.mm.
Hæmoglobin	45 %
Leucocytes	96,000 per c.mm.
Platelets	very scanty indeed.
Polymorphs	12 %
Lymphocytes	1 %
"Blasts" of monocytoid type	87 %

The day after she had been transfused with 7 litres of blood, while 6½ litres was withdrawn, her hæmogram was:

Red cells	4,500,000 per c.mm.
Hæmoglobin	90 %
Leucocytes	18,400 per c.mm.
Platelets	236,000 per c.mm.
Polymorphs	18 %
Eosinophils	2 %
Basophils	1 %
Metamyelocytes	14 %
Myelocytes	5 %
"Blasts"	58 %
Lymphocytes	2 %

Twenty-four hours after a further 7 litres had been infused and the same amount withdrawn, the hæmogram was much the same, except that the leucocytes had fallen to 12,000 per c.mm., while the red cells showed a good deal of anisocytosis and polychromasia. Five days later the blood picture was practically unchanged; and the patient, who had been extremely ill, was feeling well; she was afebrile and had lost the exquisite tenderness of the sternum that had been very striking when I first saw her. The spleen, which had been palpable (about two fingers), was unchanged.

There is, of course, no way of determining how long the remission will persist in this case, but one can hope that, using Bessis's technique (frequent "topping up" with small blood-transfusions, and urethane) it may be possible to prolong it, perhaps until the disease passes into the chronic form.

The aspect of the matter that seems to me to be of such great importance is that such exsanguino-transfusions bring about a distinct change in the cellular composition of the blood and hæmopoietic organs, which is not simply attributable to the blood that has been infused but is a vital reaction on the part of the patient. Whether, in the leukæmias, the plasma is deficient in some substance required for the maturation of white cells, or whether it contains some substance that stimulates them to divide so rapidly that maturation is impossible, I do not know. But that there is here a possibly fruitful line of research seems to be obvious.

Two striking points have already emerged. First, it is notorious that massive transfusions are badly tolerated in acute leukæmia, whereas exsanguino-transfusions cause only a minimal upset: urticaria and a few small rigors are not uncommon after about 5–6 pints has been drawn off and the same amount infused. Secondly, the published cases show that the remissions are not purely symptomatic, for both blood and marrow revert to a much more normal composition; and the remission is progressive, improvement occurring steadily for days or weeks—it is not a case of living on borrowed blood.

It is much too early to theorise about the mode of action of exsanguino-transfusion, but of its value there can be no doubt. One patient so treated has lived in good health for over 20 months (to be published by R. Cattan). To the hæmatologist, one of the most remarkable facts is that a relapse may be heralded by a sudden neutrophilia, and not, as one would have expected, by an increase of "blasts."

A. PINEY

Reviews of Books

Oral and Dental Diseases

Hubert H. Stones, M.D., M.D.S., F.D.S. R.C.S., professor of dental surgery and director of dental education, University of Liverpool. Edinburgh: E. & S. Livingstone. 1948. Pp. 896. 90s.

This is an excellent book. It is clear, concise, and well illustrated, and has full references at the ends of the chapters, so that anyone wishing to obtain further information can do so with the minimum of trouble. It deals mainly with the pathology of oral and dental diseases with clinical signs and symptoms. In some sections indications for operative as well as conservative treatment are given. In a work such as this the descriptions of operative treatment are necessarily brief; and, for example, the illustrations showing methods of removal of the mandibular third molar, though good in themselves, might perhaps have been omitted. But it is a pleasure to read a book in which one finds so much up-to-date information so clearly imparted.

Vascular Diseases in Clinical Practice

Irving Sherwood Wright, M.D., associate professor of clinical medicine, Cornell University. Chicago: The Year Book Publishers. London: H. K. Lewis. 1948. Pp. 514. 42s.

This "general practice manual" covers the whole subject from methods of examination, through clinical features, to treatment, and concludes with a valuable chapter on the industrial and medicolegal aspects of peripheral vascular disease. That it is up to date is clear from the inclusion of references to tetraethylammonium salts and rutin. Anticoagulant therapy is also fully discussed, with emphasis on the value of dicoumarol as opposed to heparin. We doubt whether a book such as this should contain a special chapter on "hypertensive ischæmic ulcers of the leg," and in the chapter on varicose veins more attention might have been paid to types of bandage. But, all in all, this is a reliable introduction to a difficult subject of increasing importance.

Pain

Harold G. Wolff, M.D., associate professor of medicine, Cornell University Medical School, New York; Stewart Wolf, M.D., assistant professor of medicine in the school. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1948. Pp. 86. 10s. 6d.

Spasticity

The Stretch-reflex and Extrapyramidal Systems. H. W. Magoun, PH.D., professor of microscopic anatomy, Northwestern University medical school, Chicago; Ruth Rhines, PH.D., instructor in anatomy in the school. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1947. Pp. 59. 10s. 6d.

These two volumes are designed to present to the non-specialist reader the results of recent neurophysiological research and its significance for clinical problems.

The book on pain begins with an account of psychophysiological investigations upon the threshold for pain and its measurement. The "bright" and "burning" elements in cutaneous pain are distinguished and discussed, and deep pain and its reference are analysed. After this the anatomy and physiology of painful states of the various organs of the body are considered, the section on headache being particularly good, as might be expected seeing how much Prof. H. G. Wolff has contributed to its elucidation. In conclusion there are brief sections on the medical and surgical control of pain. As must happen in a small book dealing with a large subject the treatment of some topics is rather sketchy, and Thomas Lewis is only mentioned obliquely as the source of an erroneous belief. Nevertheless this is a useful and stimulating account of some aspects of the neurophysiology of pain.

Professor Magoun and Dr. Rhines regard spasticity as an exaggeration of the stretch-reflex. They accept the view of Fulton and his collaborators that it is not caused by damage to the pyramidal tract, and they attribute it mainly to interruption of reticulospinal pathways which normally exert an inhibitory influence on it and which are themselves influenced by the cerebellum, the striatum, and the suppressor area of the cortex (4 S). This is a good review of one aspect of the subject, but the authors' uncritical acceptance of the ideas of the Fulton school has led them to take an over-simplified view, which, as they recognise, leaves unsolved the problem of the spinal paths concerned. The book is almost entirely neurophysiological, and in order to explain spasticity in man the neurophysiologist must have the help of the clinician.

Biology of Pathogenic Fungi

Editor: Walter J. Nickerson, PH.D., lecture medical mycology and dermatology, Tufts Col Waltham, Mass.: Chronica Botanica Co. Lon Wm. Dawson and Sons. 1947. Pp. 236. 30s.

The editor of this volume has collected essays experts from various countries, covering aspects medical mycology in which advances have recently made.

J. Lodder (Delft) and A. de Minjer (Utrecht) di torulosis (blastomycosis of the central nervous system) conclude that only a single species of yeast is involved. Carrión and Margarita Silva (San Juan, Puerto Rico) an account of the several fungi causing chromoblastom Rhoda W. Benham (New York) describes the isolation nutrition of *Pityrosporum ovale*, the yeast universally pr in dandruff scales, which is unusual among micro-organ in requiring fatty substances for growth. C. W. Emr (Bethesda, Maryland) summarises recent progress in the of coccidiodomycosis, a disease with an animal reservo wild rodents in the Arizona and California deserts. R. Ci and P. Redaelli (Pavia) describe recent work of the Ita school of mycopathology. Frederick T. Wolf (Nashv Tennessee) writes on the action of sulphonamides and biotics on pathogenic fungi. The geographical distrib of systemic fungus diseases is reviewed by D. S. Mart Durham, North Carolina. The volume concludes with chapters on the biochemistry of fungi contributed by editor, by R. L. Peck (Merck Laboratories), and by J. Williams (Bay Pines, Florida).

The work is intended rather for the laboratory wo and specialist than for the clinician. Although necess covering only part of the field, it is a welcome contribu to the study of the pathogenic fungi as living organi

A Manual of Removable Partial Denture De (Toronto: University of Toronto Press. London: O University Press. 1948. Pp. 99. 20s.).—This is a p technical book, showing illustrations and types of p dentures, by the professor of prosthodontia at Tor Mr. R. J. Godfrey. Dental surgeons will find it very usel

New Inventions

A MATCHED SET OF NEEDLE-HOLDERS

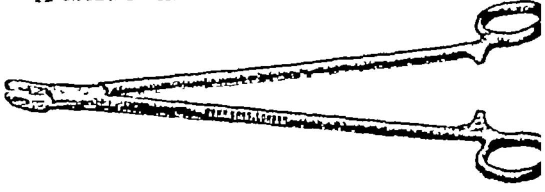

Fig. 1—One of the set of four needle-holders.

The needle-holder illustrated here (fig. 1) has l designed to have a dependable grip (fig. 2) which le itself to the tying of " touch " knots, a light sp in the shafts to prevent hand becoming tired, and r well-rounded for comfort a little larger than usual admit the occasional thicke fingers of the older surg

THE LANCET

LONDON: SATURDAY, SEPT. 4, 1948

Food and Peoples

"IF we cannot solve the problem of world resources this century, we are heading for the greatest tastrophe in history." Sir JOHN ORR's blunt rning, at the Congress on Population and World sources in Relation to the Family, held at Chelnham last week and reported on p. 388, was delivered apt hearers. The congress was arranged by the mily Planning Association of Great Britain, and tended by delegates from an extremely wide range countries. Discussion throughout four days centred und the twin problems of a growing world population d the difficulties which must be faced if they are be fed. The situation can be approached in two ys—either we must plan to increase food production ormously and to solve the outstanding puzzles of tribution; or we must find ways to stabilise pulations. Probably we shall only just avoid saster if we use both methods intelligently and with l our might. Sir JOHN ORR and his colleagues on e Food and Agriculture Organisation inevitably ncentrate on the first, while family planners look ith confidence to the second as a long-term policy fering some hope of world salvation.

The possibilities of greater food production are cidedly promising if they can be put into effect. y better methods of agriculture and better plant lection, by cultivating more ground, and by reclaimng ground now being destroyed by soil erosion, the ield can be much augmented. All this will be wasted fort, however, if distribution is not made more quitable. To produce *enough* food is merely a piece f virtuosity if a few nations are to eat well above ubsistence level while others live far below it. For time at least we may have to be content with a impler diet—on the lines, perhaps of Mr. ROY ALKER's diet of brown bread, milk, and vegetables—f we are all to eat at all. Other experiments are eginning to promise results: the cultivation of plants in water to which the necessary chemicals have been dded, and the chemical synthesis of foodstuffs were mentioned at the congress. None can say how far such methods can be developed, or how men a few centuries hence will be feeding themselves. But unless some unforeseen and revolutionary changes take place we must double our food production within the next 25 years if we are to feed the 3000 million people who will be alive at the end of the century: otherwise the hungry generations will tread us (and each other) down in quite a new sense from that which troubled KEATS. As Sir JOHN ORR pointed out, hungry people do not die quietly; and why should they?

The food issue, however, is fairly straightforward, while that of population is tortuous. Dr. C. P. BLACKER's five stages in the demographic cycle seem to promise an ultimate stability, or even decline, in the world population; but the trouble is that national populations are at different stages in the cycle. Thus France has already passed the fourth stage (in which there is a low birth-rate and death-rate, and a stationary level of reproduction) and is passing into the fifth stage of decline. Great Britain and the United States are likely to follow suit. The U.S.S.R. is in the third stage, in which the birth-rate is falling but the death-rate falling faster; while large parts of Asia and Africa are in the first stage (with a high death-rate and a high birth-rate), or the second stage (with a high birth-rate and a falling death-rate). The danger is that if population growth is left to develop on its own lines the hungry, fertile, and overcrowded nations will in the end be driven to go to war with those which are stable and well fed. Migration, it seems, is no solution. In the long run it will be to the advantage of nations in the later demographic stages to help the rest to eat and live better, for it is a constant demographic observation that the birth-rate falls when standards of living rise. Nor is this the fate of man alone: animals and insects are similarly affected. Thus populations of butterflies living under adverse conditions are commonly very fertile: whereas they reproduce much less freely when conditions improve. It is as though when conditions are bad nature ensures race survival by providing a surplus; when conditions are good she can afford to be more parsimonious. Certainly birth-control alone is not responsible for the population change which follows in the train of better standards of living. What other factors come into play are a matter of speculation, and were not discussed at the congress. One may be the later marriage common in communities where young people find it worth while to work and save in order to launch themselves more comfortably. Another may be, as Mr. F. M. MANSOUR suggested, that a large family is a constant source of occupation and pleasure to those who have few other interests; whereas in a community offering a wider range of interests, especially to women, the family no longer holds undisputed place. Again, it is not often possible in the crowded homes of an industrial town to raise a large family: some means of restriction has to be found. None of these arguments, however, applies to butterflies—or indeed to any other animal than man—and there may well be biological factors at work on the germ plasm of which we know nothing. How much effect contraceptives have on the size of populations is hard to determine; possibly their main value is to the individual. Spacing of children benefits both mother and children, protecting the lives and health of both: and it is noteworthy that in the United States, as Dr. ABRAHAM STONE pointed out, all Churches agree that such planning adds to the stability of the family, though some Churches consider observance of the "safe" period to be the only justifiable contraceptive measure.

Whether the dissemination of contraceptive technique in countries now in the first two demographic stages would help to stabilise populations and prevent "swarming" requires close and quick study. At all events it is worth trying. Unfortunately it presents special technical problems, since most of these countries are in tropical or subtropical latitudes. Most contraceptive appliances are of rubber, which perishes easily in heat, and most chemical contraceptives are made up in bases designed to melt at body temperature. It seems likely, from the reports of speakers at

Reviews of Books

Oral and Dental Diseases

Hubert H. Stones, M.D., M.D.S., F.D.S. R.C.S., professor of dental surgery and director of dental education, University of Liverpool. Edinburgh: E. & S. Livingstone. 1948. Pp. 896. 90s.

This is an excellent book. It is clear, concise, and well illustrated, and has full references at the ends of the chapters, so that anyone wishing to obtain further information can do so with the minimum of trouble. It deals mainly with the pathology of oral and dental diseases with clinical signs and symptoms. In some sections indications for operative as well as conservative treatment are given. In a work such as this the descriptions of operative treatment are necessarily brief; and, for example, the illustrations showing methods of removal of the mandibular third molar, though good in themselves, might perhaps have been omitted. But it is a pleasure to read a book in which one finds so much up-to-date information so clearly imparted.

Vascular Diseases in Clinical Practice

Irving Sherwood Wright, M.D., associate professor of clinical medicine, Cornell University. Chicago: The Year Book Publishers. London: H. K. Lewis. 1948. Pp. 514. 42s.

This "general practice manual" covers the whole subject from methods of examination, through clinical features, to treatment, and concludes with a valuable chapter on the industrial and medicolegal aspects of peripheral vascular disease. That it is up to date is clear from the inclusion of references to tetraethylammonium salts and rutin. Anticoagulant therapy is also fully discussed, with emphasis on the value of dicoumarol as opposed to heparin. We doubt whether a book such as this should contain a special chapter on "hypertensive ischæmic ulcers of the leg," and in the chapter on varicose veins more attention might have been paid to types of bandage. But, all in all, this is a reliable introduction to a difficult subject of increasing importance.

Pain

Harold G. Wolff, M.D., associate professor of medicine, Cornell University Medical School, New York; Stewart Wolf, M.D., assistant professor of medicine in the school. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1948. Pp. 86. 10s. 6d.

Spasticity

The Stretch-reflex and Extrapyramidal Systems. H. W. Magoun, PH.D., professor of microscopic anatomy, Northwestern University medical school, Chicago; Ruth Rhines, PH.D., instructor in anatomy in the school. Springfield, Ill.: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1947. Pp. 59. 10s. 6d.

These two volumes are designed to present to the non-specialist reader the results of recent neurophysiological research and its significance for clinical problems.

The book on pain begins with an account of psychophysiological investigations upon the threshold for pain and its measurement. The "bright" and "burning" elements in cutaneous pain are distinguished and discussed, and deep pain and its reference are analysed. After this the anatomy and physiology of painful states of the various organs of the body are considered, the section on headache being particularly good, as might be expected seeing how much Prof. H. G. Wolff has contributed to its elucidation. In conclusion there are brief sections on the medical and surgical control of pain. As must happen in a small book dealing with a large subject the treatment of some topics is rather sketchy, and Thomas Lewis is only mentioned obliquely as the source of an erroneous belief. Nevertheless this is a useful and stimulating account of some aspects of the neurophysiology of pain.

Professor Magoun and Dr. Rhines regard spasticity as an exaggeration of the stretch-reflex. They accept the view of Fulton and his collaborators that it is not caused by damage to the pyramidal tract, and they attribute it mainly to interruption of reticulospinal pathways which normally exert an inhibitory influence on it and which are themselves influenced by the cerebellum, the striatum, and the suppressor area of the cortex (4 S). This is a good review of one aspect of the subject, but the authors' uncritical acceptance of the ideas of the Fulton school has led them to take an over-simplified view, which, as they recognise, leaves unsolved the problem of the spinal paths concerned. The book is almost entirely neurophysiological, and in order to explain spasticity in man the neurophysiologist must have the help of the clinician.

Biology of Pathogenic Fungi

Editor: Walter J. Nickerson, PH.D., lecturer medical mycology and dermatology, Tufts College, Waltham, Mass.: Chronica Botanica Co. London: Wm. Dawson and Sons. 1947. Pp. 236. 30s.

The editor of this volume has collected essays by experts from various countries, covering aspects of medical mycology in which advances have recently been made.

J. Lodder (Delft) and A. de Minjer (Utrecht) discuss torulosis (blastomycosis of the central nervous system) and conclude that only a single species of yeast is involved. A. Carrión and Margarita Silva (San Juan, Puerto Rico) an account of the several fungi causing chromoblastomy Rhoda W. Benham (New York) *describes the isolation* nutrition of *Pityrosporum ovale*, the yeast universally pr in dandruff scales, which is unusual among micro-organi in requiring fatty substances for growth. C. W. Em (Bethesda, Maryland) summarises recent progress in the st of coccidiodomycosis, a disease with an animal reservoir wild rodents in the Arizona and California deserts. R. Cif and P. Redaelli (Pavia) describe recent work of the Italian school of mycopathology. Frederick T. Wolf (Nashville, Tennessee) writes on the action of sulphonamides and anti-biotics on pathogenic fungi. The geographical distribution of systemic fungus diseases is reviewed by D. S. Martin of Durham, North Carolina. The volume concludes with two chapters on the biochemistry of fungi contributed by the editor, by R. L. Peck (Merck Laboratories), and by J. W. Williams (Bay Pines, Florida).

The work is intended rather for the laboratory worker and specialist than for the clinician. Although necessarily covering only part of the field, it is a welcome contribution to the study of the pathogenic fungi as living organisms.

A Manual of Removable Partial Denture Design (Toronto: University of Toronto Press. London: Oxford University Press. 1948. Pp. 99. 20s.).—This is a purely technical book, showing illustrations and types of partial dentures, by the professor of prosthodontia at Toronto, Mr. R. J. Godfrey. Dental surgeons will find it very useful.

New Inventions

A MATCHED SET OF NEEDLE-HOLDERS

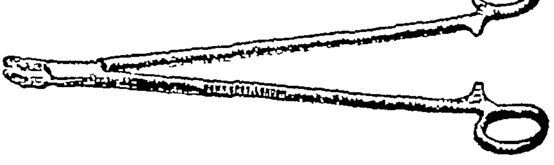

Fig. 1—One of the set of four needle-holders.

The needle-holder illustrated here (fig. 1) has been designed to have a dependable grip (fig. 2) which lends itself to the tying of "no-touch" knots, a light spring in the shafts to prevent the hand becoming tired, and rings well-rounded for comfort and a little larger than usual, to admit the occasional thickened fingers of the older surgeon.

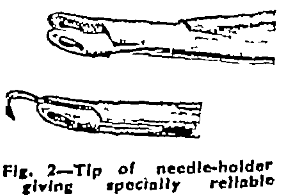

Fig. 2—Tip of needle-holder giving specially reliable grip.

The needle-holders are made in sets of four lengths—5 in., 6 in., 7 in., and 8 in.—to allow for various depths of wounds. Messrs. Down Bros. are the makers.

London.

Harold Dodd, F.R.C.S.

Medullary Nailing

DURING the second half of the late war orthopædic geons in Britain and Western Europe began to counter, among prisoners repatriated from Germany, ctures which had been treated by inserting a el nail throughout the length of the marrow cavity. is method, originally described by KÜNTSCHER the Vienna Surgical Congress of 1940, had been eived in Germany with early coldness and later thusiasm, and the published reports on it had been ted here with some scepticism,[1] but it was then en to be a practical success. Now that the best rt of a decade has elapsed. intramedullary nailing routine in many German centres, where it would unusual not to treat a fresh fracture in this way. e latest edition of BOEHLER's famous textbook[2] cludes a special volume on the applications of the chnique. The textbooks of SOEUR[3] and ROCHER[4] itness its adoption in Belgium and France, and ESTERBORN[5] has described results obtained in andinavia. But in Britain and the U.S.A. surgeons e still slow to accept it, and little more than an casional case-report is to be found in the journals. is not as if the principle of axial control were new. he intramedullary bone peg is an old—and usually efficient—friend; LAMBOTTE,[6] before the first orld war, experimented with the clavicle and other ones, as later did that versatile surgeon HEY GROVES. ore recently, LAMBRINUDI[7] used central Kirschner ires for stabilising difficult fractures of the forearm ones. The issues may be stated somewhat as follows.

In post-war Europe, with its shortage of hospital eds and materials and lack of skilled aftercare and hemotherapy, the advent of the Küntscher nail was normously advantageous. Patients could be sent ome after a week or two, usually without plaster plintage, and often returned to light work after a month. Physiotherapy was unnecessary when, for ractical purposes, the fracture had been abolished t the outset of treatment. Of BOEHLER's three amous tenets of absolute reduction, absolute fixation, and maximum function, it was for the surgeon o achieve the first, and the insertion of the right-size nail provided the second and permitted the last. In Britain and America a different situation, with a sufficiency of penicillin and good-quality metal appliances for internal fixation, accounted for the hesitant attitude towards the new method. When open reduction was necessary, vitallium plates and screws of known performance were used. Deliberate leisurely open bone operations, protected by chemotherapy and transfusion on the scale the war had made possible, still seemed promising enough to make surgeons reluctant to contemplate quite a different technique. But plates and screws have their disadvantages. They impose mechanical conditions at the fracture site with which the osteoblasts must comply or the technique will fail; and they may nullify the longitudinal compression forces essential to sound union. Hence the various stratagems—the coaptors of DANIS,[8] and the slotted plates of EGGERS[9]—designed to allow the biological element in union full play. The Küntscher nail, on the other hand, is an axial rod on which the bone fragments are threaded and which converts all the forces of weight-bearing and muscle spasm into longitudinal compression at the fracture gap.

The technique and its applications vary in different hands. Where KÜNTSCHER and his colleagues would use the nail for almost every closed fracture in adults, others reserve it for difficult cases. On p. 387 in this issue Mr. FRAENKEL describes the standard methods used at Schleswig and Kiel, where a "closed" technique is usual, the fracture being reduced by traction and the nail inserted through a stab over one end of the bone under fluoroscopic control. KÜNTSCHER himself never exposes the fracture, abhorring the periosteal reflexion and fall in local pH which set back healing; and if closed methods fail he resorts to old-fashioned traction or plaster. Other surgeons do not hesitate to perform open reduction and to introduce the nail at the fracture level by a retrograde method. At some clinics no external splintage is used, whereas at others a plaster cast gives the surgeon a good night's rest.

The clinical, functional, and economic advantages of nailing are so obvious that we may reasonably pay particular attention to its disadvantages and to the minority of failures. As MCFARLAND[10] has said—and it cannot be repeated too often—"the fracture patient should be at least no worse off after treatment than if left alone; he should be positively better treated than untreated; operation should leave him in a better state than non-operative treatment; and the added risk of operation—a real one—should be commensurate with the added benefit." The sepsis-rate in the great mass of German nailing operations is somewhere in the region of 5%,[11] a figure which, while acknowledging our own imperfections, we must regard as 5% too high. But against this, those who nail regularly regard infection as a nuisance but not a menace. It does not lead to a general osteomyelitis, and the nail must *not* be removed, for its splinting action is now doubly important and it drains the pus to the surface at the site of introduction, where simple drainage of the soft parts may be all that is needed. Fat-embolism seems to be mainly a theoretical danger, except perhaps in the femur; SOEUR records only one case where it possibly occurred. Does the nail hinder callus formation? Apparently not; in KÜNTSCHER's famous animal experiment, the insertion of a nail into an intact bone provoked ensheathing callus formation in the absence of any fracture. The question of X-ray control is a major one. The free use of screening makes nailing a rapid and trivial operation, but the hazards are too serious to be ignored. As SOEUR advises, it should be abandoned in favour of repeated radiography as for the insertion of a Smith-Petersen pin, a deliberate, often tedious, and major operation. It is obvious. too. that there

the congress, that the women in these countries would welcome advice on the spacing of children ; and there is little danger that the spread of such advice would lead to race suicide since fertility is very highly valued in such countries. Yet until an appropriate and accessible contraceptive can be devised for hot climates, such advice cannot be an effective measure for population control. In the task of solving this and other problems of fertility the new international committee for research into family planning, set up at the congress, will have an important part to play. In the long run, however, the best means of reducing the birth-rate may be to raise world standards of living—a policy worth achieving on many grounds. We are constantly getting opportunities to look ahead and plan our destiny, though we generally ignore them. This seems to be a situation in which duty and interest point the same way—towards an effective world plan for food and a rise in living standards. As the Rev. Joseph McCulloch put it, *man is born to know more and more what he is doing. His survival may well depend on his ability to accept this privilege and responsibility.*

Function and Dysfunction of the Bladder

The normal function of the bladder has received too little attention from the clinician. This viscus is unique in that, though its activity depends on an autonomic reflex, during life a considerable degree of voluntary control is acquired. Perhaps for this reason, the factors affecting bladder function are many and varied—and as yet imperfectly understood. The mechanism of micturition has been clarified to a considerable extent by the physiologists. It is generally agreed that the activity of the bladder depends on a reflex arc, both arms of which lie in the pelvic parasympathetic nerves, and which is completed in the 2nd, 3rd, and 4th sacral segments of the cord. The exciting stimulus is provided by distension of the bladder. In addition, an overriding cortical control of bladder activity is exercised by inhibitory impulses relayed from the higher centres to the sacral region by spinal pathways. The site of impact of these impulses is thought by Denny-Brown and Robertson[1] to be on outgoing neurones of the spinal cord, and they in some way interfere with the completion of the reflex arc. Thus a person may have a sensation of bladder distension, but the viscus will not normally contract until inhibition is voluntarily removed. Desire to void urine depends on bladder distension and also on the rate of distension ; the more rapidly the bladder is filled the earlier the desire appears. But a strong and urgent desire to void also arises during bladder contractions : hence the micturition accompanying bowel opening and hence the desire to void brought on by the psychical stimulus of hearing running water. Intravesical pressure, which is the sum of the pressure exerted by the tonicity of the bladder wall and the intra-abdominal pressure, may vary independently of bladder-distension. Thus in laughing the intravesical pressure rises but the distension remains the same, and desire to void will not be brought on unless the intravesical pressure was already so high, or the urethral sphincter so weak, that the internal sphincter is forced and the bladder reflexes are brought into play. The effect such forcing of the internal sphincter probably ca for the common urgent call to micturate on getting in the morning. Emotional stress presumably by stimulating bladder contractions.

Bladder dysfunction, particularly that resu from neurological disorders, has been studied ex sively, especially in America, by means of cystome a method first practised by Mosso and Pellacani 1882. This technique is an attempt to parallel th physiological filling of the bladder by slowly instilli fluid through a catheter and noting the fluctuations intravesical pressure as registered by a manomet A reaction to distension denoting involvement those parts of the nervous system concerned wi bladder function may be one of the earliest signs a developing neurological lesion. Lesions of the pel parasympathetic nerves involving the vesical ref arc affect the motor activity of the bladd McLellan[2] has noted significant differences, whi he cannot fully explain, in the bladder chang resulting from lesions involving the posterior nerv roots, as in tabes, and those involving both arms the reflex arc, such as destruction of the sacral cor In both cases sensations and reflex activity are lo but in the former the bladder is characterised by lar capacity and lack of tone, whereas in the latter it i small and hypertonic. Owing to the close appo of the afferent and efferent spinal pathways conce with bladder function both are commonly involve in the same lesion. For this reason disturbances bladder sensations and impairment of cortical inhibi tory control are frequent concomitants. The are of the cortex concerned with bladder function has not been accurately defined, though according Fulton[3] bilateral cortical lesions involving parts areas 4 and 6, lying in the medial surface of th hemisphere, cause loss of volitional control on bladder reflexes, with urinary incontinence. Th normal volitional act of micturition is said to depe on integration emanating from the hypothalamic are as well as from the cerebral cortex. Thus, lesions the hypothalamus cause a failure of coördinati between the reflexes concerned with micturition.

The urinary incontinence which is one of the mo constant and most distressing dysfunctions of t aged is discussed on another page by Dr. Wilso In his view it is an effect of neuromuscular overactivit Local conditions increasing the irritability of t bladder and its outlet are partly responsible for th overactivity, but impairment of cortical contr whether or not accompanied by demonstrable orga lesions, is the main factor. Wilson urges the impo tance of the semisomnolent state into which ag patients commonly decline when kept in bed, th inhibitory function becoming involved in the gene sluggishness. Apart from the treatment of infectio of bladder or vagina, Wilson treats these patie by re-educating their inhibitory function and enco aging them to lead an active mental and physical li The probable effect on bladder function is yet anoth argument against allowing old people to beco bed-ridden before they must.

eclude special payments, if the executive council elieves them necessary for an equitable income, or erhaps to secure a candidate better suited to local quirements. Possibly, however, this might come under e next suggested category, where a vacancy is to be dvertised for an area which in the past has always tracted too few doctors. The third situation quoted is e where a doctor might be unable to manage on the me he expects to receive under the new service. may be the plight of many a rural practitioner, se practice, while no less arduous, is numerically ller than that of his urban colleague. Wherever, too, executive council considers that an extra doctor is led, for geographical or other reasons, in a small munity, it seems only fair for them to consider ial payments not only for the extra doctor but also any neighbouring practitioner whose income might seriously prejudiced through the introduction of a comer. Lastly, it is suggested that special considera- might be given to the practitioner with an abnormal ber of aged and chronic sick on his list, or in the allel case of a vacancy in an area where large numbers such people reside. Presumably this would refer to s and similar places in which invalids tend to settle, to towns from which, at times of industrial depres- , a high proportion of the younger people have ved.

hese suggestions do not preclude executive councils m putting forward other cases in which they think ucement payments should be made, though the nistry hopes that, wherever possible, minor hardships or ficulties may be met through the annual fixed payment £300 allowed under regulations, thus avoiding a ltiplicity of claims on the inducement fund. All oposals from executive councils "will be referred by e Minister to the Medical Practices Committee for vice on the payments to be made in individual cases ithin the total sum available for distribution for ducement payments." Each year the executive council, consultation with the local medical committee, will view all payments approved by the Minister and report the need for their continuance. Hardship will some- mes not be evident at once; in fact, it may not become vious, even to the doctor himself, until the numbers patients on practitioners' lists have been agreed and e first quarterly payments made. But it should not difficult, if authority allows, for the Medical Practices ommittee to sanction immediate interim payments to e more obviously needful, while keeping enough in serve to make retrospective payment to doctors whose eeds declare themselves later.

HISTAMINE FOR MIGRAINE

BOTH histamine and anti-histamine drugs have been ecommended in the treatment of migraine. Butler and omas[1] were enthusiastic advocates of the former, ich they administered intravenously by a rather borate technique. Cautious-minded readers of their iginal papers may have been impressed more with the ress of the régime than with the benefits accruing m it. Histamine has been used in migraine at the yo Clinic since 1937, and Macy and Horton[2] have ely assessed their results, carefully excluding instances what they term "histaminic cephalalgia."[3] The cases migraine, numbering 144, were divided into two ups: (1) 124 treated with histamine only, whether bcutaneously, intravenously, or both; and (2) 20 ated by the original Butler-Thomas technique, with ravenous injection of a 1 : 500,000 solution of histamine se, coupled with epinephrine and ascorbic acid. It proved difficult to judge the efficacy of the drug. Macy and Horton rightly remark that migrainous subjects are particularly liable to headache of other types, which will lower the threshold for an actual attack of migraine; but they believe that confusion from this cause is avoidable. They found that in 23–33% of cases the syndrome was unchanged by histamine, irrespective of the route of administration. About 60% showed significant improvement, which was apparently most pronounced with combined subcutaneous and intravenous injections. But of 88 patients whose condition was improved, 85 had a recurrence when the histamine was reduced or discontinued. The authors cautiously conclude that "histamine may prevent some attacks of migraine in some cases." In their opinion histamine, though neither a specific nor a truly curative agent, will continue to have a place among the prophylactic measures against migraine.

INFECTION BY TRAIN

THE pollution of railway tracks by excreta from train closets has not yet received as much attention in this country as it has in the United States, where the joint committee on railway sanitation set up by the Association of American Railroads has recently sponsored a great deal of careful research with the coöperation of the United States Public Health Service and the epidemiological department of the Johns Hopkins school of hygiene and public health at Baltimore. The results of these inquiries have been published in a series of special reports, of which the most interesting is that by Maxcy,[1] who made an exhaustive survey designed to find out how far polluted railway tracks were a cause of the spread of disease and in particular of enteric fever. After a special study of exposure to this source of infection through residence in proximity to railway tracks, employment on such tracks, or the consumption of water-supplies which might be polluted by railways at some point in collection and distribution, he could not establish the existence of a danger to public health from the method of disposal of fæcal wastes employed by railways. The further studies, summarised by Wolman and Clark,[2] are mainly quantitative, being based on observation of the toilet habits of 2000 persons travelling 320,000 miles by train during 6261 passenger hours. Excreta from these persons were collected in sealed containers carried underneath the coaches, and it was found, for instance, that along the 226 miles between New York and Washington about 0·694 lb. (dry weight) of sewage solids were being deposited per yard of track per year.

The construction of the closets in British trains and the habits of the passengers using them are probably sufficiently similar for the American results to be roughly applicable over here. As Mr. Chapman Pincher[3] pointed out last year, the potential dangers of current railway practice are obvious, but hitherto in Great Britain, as in the U.S.A. there has been hardly any evidence of the spread of disease by this means. Pincher suggested that poliomyelitis was being spread in this way, but among the many accounts of the large number of local outbreaks which made up last year's epidemic only one[4] has mentioned the residence of cases in proximity to main-line railway tracks. However, in this particular outbreak, in a London borough, the distribution of cases was very striking. The main line carrying ships' passengers from Tilbury Docks to St. Pancras station passes through Tottenham on a high and exposed embankment, whereas thereafter it runs through Islington in a cutting. At Tottenham,

is no place for the occasional nailer, any more than there is for the occasional surgeon in any field, and the new method should be tried only at the large fracture centres in this country. It is being so tried, and the first reports will be awaited with interest. Finally, the purely orthopædic applications of the intramedullary nail must not be forgotten, for in arthrodeses, osteotomies, and bone-lengthening and bone-shortening procedures of all kinds, KÜNTSCHER has shown that it has a place of great value. Here is a field for experiment open to every orthopædic surgeon.

Annotations

PENICILLIN IONISATION THERAPY

LOCALISED infections of surface tissues are now commonly treated by simple topical applications of penicillin; but the not-infrequent failure of this method has caused the depth of penetration and degree of absorption to be questioned, and Sophian[1] has shown experimentally that tissue penetration is very superficial and absorption slight. Iontophoresis has been used in the hope of overcoming these difficulties but there have been conflicting reports on its effectiveness, and Hamilton-Paterson[2] has obtained results which seemed to show that penicillin salts are poor conductors or non-conductors of the electric current. Moreover, Popkin[3] was unable to demonstrate penicillin in the blood of patients treated by penicillin applied to the skin by iontophoresis.

Recently, Pereyra[4] has compared the specific-conductivity curves of penicillin G and crude sodium-penicillin extract with those of 'Mecholyl' (acetyl-β-methylcholine) and sodium salicylate, both commonly used in iontophoretic treatment, and with sodium chloride, a highly ionising inorganic salt. The crude penicillin was a better electrical conductor than stock sodium penicillin G, and when used in the right concentration was little inferior in this respect to mecholyl chloride or sodium salicylate. Thus, Hamilton-Paterson's inability to demonstrate conduction in his experiments may have been due to the low concentrations of penicillin employed—namely, 25–50 units per ml. Pereyra points out that 8000 units per ml. of sodium penicillin G or 5000 units per ml. of crude sodium-penicillin extract gives a penicillin concentration of 0·5%—a strength at which satisfactory results are obtained from mecholyl chloride and sodium salicylate. This concentration of penicillin is well tolerated by the skin and mucous membranes; and Pereyra found that the application of solutions in a glass chamber was more effective than by the more usual gauze-pad technique.

Absorption with iontophoresis was compared with that from ointments rubbed into the skin of the antecubital area for 15 minutes. Blood was withdrawn from the vein of the opposite arm at intervals up to an hour after treatment, and urine was collected for 2 hours. After neither innunction nor iontophoresis could penicillin be detected in the blood; in the urine, however, penicillin appeared within 15 minutes of iontophoresis. The presence of this urinary penicillin was found to depend on the application of the negative electrode only to the solution; it was estimated that the skin transference of penicillin was at the rate of about 1 unit per sq. cm. of skin per minute. The alkalinisation of the solution by the current, using 5 milliamperes for 15 minutes, caused no appreciable destruction of penicillin. To limit this alkaline shift, only distilled water should be e for dissolving the penicillin.

The application of penicillin by iontophoresis offers definite advantages over parenteral and topical administration in the treatment of locali surface tissue infections; the concentrations of p achieved at the site of application much exceed th possible by the parenteral route. This has been by Pereyra and Landy[5] who showed that penicil when administered parenterally fails to heal chancr ulcers, but when applied locally by iontophoresis p duces prompt remission; and a similar finding been made by Pereyra in a series of 13 cases.

INDUCEMENT FUND

EXECUTIVE councils have lately been seeking the vie of local medical committees on the adequacy of gene medical services in their areas. Account is being tak of the numbers of the population (including, natural those who have elected to seek medical advice private and of the doctors engaged in general practice as prin pals or as assistants, together with any local social topographical features which might make the provi of a medical service more than ordinarily difficult.

Presumably the next step will be to try to attr extra doctors to those areas found to be under-provide In areas where doctors' lists approach or exceed t permitted maxima, they have the choice of curtaili the acceptance of new patients or of arranging for adi tional assistance. In such an area a newcomer sho find an immediate and growing income, which could enhanced at first, if need be, by acceptance of the ann fixed payment. A greater difficulty, until the hou shortage has eased and health-centre building becom possible, may well be the finding of suitable accommod tion in which to practise and to live. Elsewhere, a notably in sparsely populated moorland areas, qu different factors may hinder executive councils improving, or even maintaining, an already inadequa service. It was for such areas that the inducement pa ments were primarily intended; and in a timely lett the Ministry of Health reminds the councils of a fu from which such payments may be made. The mon set aside for this purpose is equal to 1% of the to central pool for the payment of general practition but it comes from a separate grant and is not a cha on the pool. This money is immediately available, a the Minister intends that the first payments sh wherever possible, be made by the end of the prese quarter. He therefore urges early action by exec tive councils, in consultation with the local medi committees, to assess and bring to his notice

> "any cases where they are satisfied that general medi services adequate to the needs of the district cannot provided, or cannot reasonably be expected to be maintaine without an inducement payment, and the amount of t inducement payment which they consider necessary to enal an adequate service to be provided or maintained."

The council is reminded that mileage payments to ru practitioners are likely to be at least double tho received in the past, but that the special-subsidy porti of the old insurance mileage fund has ceased. From th fund special payments used to be made in respect patients to whose homes access was difficult; it al subsidised heavy expenses such as those caused by t necessary upkeep of scattered branch surgeries. Fro now on such assistance will come directly from t inducement fund.

The Minister's letter suggests four other types of ca where inducement payments will probably be neede The first is where a vacancy has been advertised but applications have been received; but the receipt of o or more applications for an advertised post should n

INTRAMEDULLARY NAILING OF FRACTURES

THE PRACTICE AT KIEL

G. J. FRAENKEL
M.A., B.M. Oxfd, F.R.C.S.
SURGICAL REGISTRAR, GENERAL HOSPITAL, NOTTINGHAM

I HAD heard of Küntscher's method of intranedullary nailing intermittently during the later years of the recent war from British, Swiss, and Dutch surgeons. The remarks of the British surgeons had been unfavourable, those of the Swiss and Dutch very favourable. As had seen no account of the method in the more widely irculated British journals, I was unable to study it ntil I visited the University of Kiel last year, where Prof. erhard Küntscher first practised this technique. and where Prof. H. Griessmann and Dr. Richard Maatz indly showed me the method. operations, results, and iterature. I am not in a position to assess the value of he method with any authority, but some of my colleagues may be interested in what I saw of it.

The principle of intramedullary fixation is old, and no ovelty is claimed for it. The present method is an xtension of the principle of the Smith-Petersen nailing f fractures of the neck of the femur to fractures of almost ll long bones, and was presented by Professor Küntscher o the Chirurgen-Kongress in Berlin in 1940; it was ceived very unfavourably by his German colleagues, ho, however, became enthusiastic about it shortly rwards.

he basis of the method is that a long slightly flexible nless-steel nail, approximately V-shaped in cross-ion, is introduced into the marrow cavity of the tured long bone from near one end: then, after tomical reduction of the fracture by manipulation, the l is driven across the fracture site, under radioscopic trol, into the other fragment sufficiently far to secure olute immobilisation. In a suitable case no additional mobilisation is required, and thus there is no loss of ction or joint stiffness. The nursing of a patient with ractured femur, for example, is much easier, and his eral health far better, than during immobilisation a Thomas splint. Further, the physiological stimulus function is conducive to early and firm union, and scle wasting is diminished.

The method has been applied to simple, compound, and hological fractures, and for immobilisation in arthro-is, osteotomy, and the treatment of pseudarthroses.

The only essential requirements for nailing are an ray plant suitable for screening (the apparatus at el is superior in point of smallness and mobility to any ave seen) and an assortment of nails of suitable sizes. Kiel the nails are made locally by the hospital instrunt-maker, and a suitable nail is selected by measurents on radiograms incorporating a scale. If there no suitable nail in stock, the instrument-maker manuctures one, usually in less than 24 hours (other hospitals legraph for them). It is important that the nail should t be too thick, because such a nail can become so mly wedged at the "waist" of the bone as to cause e greatest difficulty.

The first essential is perfect reduction. At Kiel this achieved with blocks and pulleys and, in special cases, keletal-traction wires and other mechanical apparatus. he reduction is checked by very brief screening, a small cision is made over the site of entry of the pin, and the rtical bone is pierced to the marrow cavity. Either e guide pin or the nail (see below) is then introduced into e marrow cavity and propelled along it, a further brief ew on the screen being taken as it crosses the fracture e. In the case of a guide pin the nail is now threaded wn and the pin withdrawn, the small incision is closed, d check films are taken. The operation usually lasts out 10–20 min. and is carried out under 'Evipan,' inal, or brachial block anæsthesia.

The necessity for screening is a major drawback. is is realised, and the most stringent precautions e taken. The danger of sepsis appears appalling at st, and yet it has given rise to practically no trouble, ough penicillin has not been available for any of these cases. The danger of fat-embolism also has been found to be entirely theoretical. Though it undoubtedly must occur, no clinical effects have been observed.

The following details are extracted from a careful analysis[1] of 155 cases nailed at Kiel from Jan. 1, 1944, to May 1, 1946—i.e., during the time of the worst chaos there (the clinic stands in acres of rubble and was hit frequently).

Femur

Subtrochanteric fractures are very satisfactorily controlled with a short special nail (fig. 1).

Shaft (fig. 2): a guide pin is usually employed, and it or the nail is of help in manipulating the upper fragment.

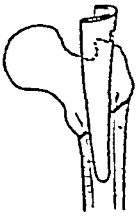

Fig. 1—Special nail for subtrochanteric fracture of femur.

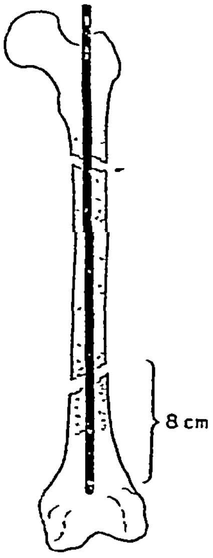

Fig. 2—Nailed fracture of shaft of femur.

Supracondylar fracture: the nail is of great value in preventing angulation, but additional immobilisation is required because of the width of the marrow cavity.

In all these cases the nail is introduced just medial to the greater trochanter.

Of 35 simple fractures 27 were stable; the others required additional immobilisation, but angulation was absolutely prevented. In stable cases the patients started walking in 7–42 days. Two patients with associated multiple injuries died; operation was an error of judgment. All others were symptom-free after 3½ months. No nails were removed before 4 months. Of 7 compound fractures 3 were stable without additional immobilisation, all united, and only one case with gross loss of soft tissue had loss of function.

Four pathological fractures were nailed and irradiated, and 2 osteotomies nailed, with excellent union.

Tibia

Owing to the hourglass shape of the marrow cavity a special double nail is inserted from the region of the tuberosity or of the medial malleolus (fig. 3). The first nail carries a wedge which forces away from it the following second nail, thus securing the lower end firmly.

Of 46 simple fractures all those put up with the double nail were stable; but 10 nailed with a single nail because of multiple fractures which the double nail could not pass, or for other reasons, required additional plaster. Even in these cases the position was far better than could have been otherwise achieved. One patient died in the 5th week of other injuries; 1 aged 81, with a fractured femur also, died of pulmonary embolus and bronchopneumonia. All others had a good anatomical and functional result. No nails were removed before 3 months, and there was difficulty in extraction in 2 cases. Of 15 compound fractures 14 were stable. One patient died of pulmonary embolus in the 3rd week; and 1 died of multiple injuries and shock (air-raid casualty). Two pseudarthroses united after freshening and nailing.

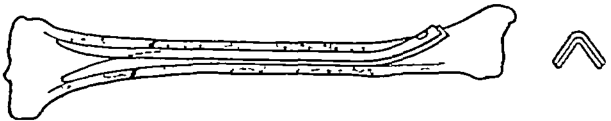

Fig. 3—Double nail for fractured tibia.

Humerus

This can be nailed with ease from below or above (figs. 4 and 5). The early and full function of arm and hand is remarkable.

Ten closed fractures (7 nailed from above, 3 from below) were all stable and achieved good union with full function. Nailing of 2 pseudarthroses with freshening led to firm union. In a compound infected fracture with multiple injuries which all but one (a doubtful case) of the 17 confirmed cases were in people who lived—or in one case worked all day—within a quarter of a mile from this railway. In Islington, on the other hand, the incidence was low and there was no such aggregation of cases near the railway. It seems reasonable to argue that incoming travellers from abroad would be likely to include a particularly high proportion of carriers of poliomyelitis; and also that virus in their excreta, deposited from the train closets, would be more readily air-borne from the top of an embankment than from the bottom of a cutting. This one example cannot be considered proof of the hypothesis, but it should spur on the Railway Executive to reconsider the arrangements for the disposal of human excreta on their trains. The sanitary engineer who designs an inexpensive device which will collect and contain train sewage during the journey and which can be rapidly emptied into a sewer at the end of the run should be assured of a handsome reward.

JUVENILE OSTEOCHONDRITIS OF THE SPINE

CHILDREN with the disorder described by Scheurmann [1] as kyphosis dorsalis juvenilis seldom make any complaint; yet many are deformed, with irregularities of ossification of the vertebral bodies; and later, under stress or strain, these changes can give rise to pain. The evidence suggests that this condition of juvenile osteochondritis is at least partly instigated by malnutrition during growth, and that benefit can result from an improved dietary.[2] In this country the worst cases have been observed among the younger members of large families in certain Oxfordshire villages where wages were low before the late war, and where severe dental fluorosis is also found among the inhabitants. In the occasional cases seen in children from the higher income groups there is a history of long-continued ill health or feeding difficulties. The geological distribution of cases indicates an association with some factor closely related to fluorine, a trace element which may itself interfere with enzyme systems concerned in the calcification of bone.[3]

Kemp and his colleagues,[4] in an investigation of the ætiology of Scheurmann's disease, compared two groups of boys—the first from a public school and the second from the poorer quarters of Oxford. Some of the boys in the first, and presumably better-nourished, group had dental fluorosis, whereas none of the second group, who were not exposed to a high fluorine intake, were thus affected. Both these groups were compared with a third, living in a village community where dental fluorosis affects nearly all the inhabitants and considerable poverty formerly prevailed. In this group spinal changes were more than three times as common as in the other two groups, and the disturbances were in some instances more severe. Although spinal changes are not always found with dental abnormality (" mottled enamel "), the probability of spinal changes in a community can be gauged with fair accuracy by examining the teeth. The investigators conclude that in view of the association recognised in other countries, of endemic dental and osseous fluorosis with malnutrition, the possibility of a similar association between dental fluorosis and juvenile osteochondritis must be borne in mind.

Whatever the intimate pathology of the disease, the practical implications of these findings are evident. Probably even the most severe cases could be prevented by a good dietary; and special attention should be given to children living in rural areas, particularly where dental fluorosis is prevalent. Thus a condition hitherto regarded as chiefly the concern of the orthopædist is in all probability completely preventable by proper nourishment.

HOSPITAL LIBRARIES

MANY doctors regret that they have not more time for professional reading. What time they have can be used best if textbooks and journals are within easy reach. Group practice enables some to have a selection of books at hand; and a similar advantage will be gained from health centres. Here and there the general practitioner finds a hospital where he is welcomed to a reading-room.

The reorganisation and grouping of hospitals opens the way to a better-organised library service; and management committees will now have to decide on the resources to be offered to their staffs. There seems to be need for a general policy, particularly in view of the continuing shortage of textbooks. In the past some local authorities took the view that their medical staffs should provide their own books; but then the cost was much less than now, and committees will certainly be called on to review this decision. Any provision will have to be made on a group basis since the supply would soon be exhausted if every hospital had even £50 to spend on books and journals. Perhaps it will be possible to enlist the help of the public libraries, which are increasingly used by serious readers and those needing books of reference, whether in commerce, industry, or the professions. Possibly each group of hospitals should aim at a centralised library, stocked in conjunction with the public library and staffed under its auspices, since the value of a library largely depends on the efficiency of the librarian. Management committees also have obligations to other members of hospital staffs. In particular, the and other auxiliaries need a professional library, the public library is not readily accessible prov should be made for their recreational reading; scription to a commercial lending library is enough to ensure a tempting selection. At least public librarian, with the cordial consent of the ho committee, has arranged to supply and staff a ho library to meet the needs of each section of the and the patients. The Minister of Health has draw attention of management committees to patients' lib as a medium for continued voluntary work withi hospital; but many voluntary librarians realise tha efficiency of their work would be considerably enha by coöperation with the public librarian. This al benefits patients by helping to meet their special req which tend to cover an increasing range. In long institutions such as sanatoria and mental hospitals is particular need for a comprehensive service; an example set by Crichton Royal has already been foll by another large mental hospital, which has establi in its grounds a branch of the county library.

The extension and integration of such a scheme req a good deal of planning: the areas of the hospital s do not coincide with those of the library author resources may be available in one place and n another; and librarians may find it hard to under additional work which may make considerable dem Clearly the regional boards will need a profes adviser to plan for the whole region; and he will to find in the medical-school librarian a sympat professional colleague; since the Goodenough r was published, the medical schools have shown g readiness to appoint trained librarians. If, as B.M.A. curriculum committee[1] suggests, "the libr indispensable and the student must be guided in its so that in his later professional life he will have in constant ally and friend," then a professional libr is an essential member of the staff.

[1] Training of a Doctor: Report of the Medical Curriculum mittee of the British Medical Association. London, 1 para. 93.

anchuria, Burma, Malaya, and parts of Africa—lived intermediate levels, getting 2500–2875 calories; while e remaining 50%—about a thousand million in eastern sia and middle America and in a large part of Africa—t less than 2500 calories. The low-income countries ve a high fertility, and as long as this fertility is aintained every modern improvement which leads to reduction in mortality leads to a spurt in population owth. The rice economy, on which millions of people pend, is peculiar. There is scarcely any other method production capable of yielding so many units of food ergy per unit of cultivated land as paddy growing, d it can be doubled by the use of fertilisers and lected plants. Conceivably it might be increased rapidly ough to outstrip the needs of the growing population, t this is doubtful. We must, in short, find more rapid eans of reducing human fertility. An improvement standards of living, new methods in agriculture, d the introduction of planned parenthood are all plementary measures.

r. H. M. SINCLAIR also emphasised the gain in production which could be expected from better cultural methods and the control of infestation, by extending cultivation to new areas. He touched some new methods: cultivation of soil-less plants, the synthetic production of fats from carbon oxide and steam.

r. A. M. DURAND-WEVER (Germany) said that in Russian Zone and in Berlin Germans have been ng on 1200–1800 calories daily for the last three years. quality of their food is poor, with shortage of fats l proteins and no fresh fruit and vegetables. The th-rate before Hitler, in 1933, was 8·7 per 1000; at height of the Hitler propaganda it rose to 14·9, l is now down to 9·2. The death-rate was lowest in 38, at 5·8 per 1000. It rose to 55 after the capitulation d is now 16.

Mr. ROY WALKER remarked that we shall soon have feed more people than can possibly be fed at the el at which people are now trying to feed themselves. diet meeting all requirements is provided by wholeal bread, fruit, vegetables, and milk; and to produce h a diet ${}^{3}/_{10}$ of an acre per head suffices, instead the $2^{1}/_{2}$ acres per head needed when animal food her than milk is taken. On such a vegetarian diet e world could get by immediately.

POPULATION TRENDS

Prof. P. K. WHELPTON (U.S.A.) pointed out that in rthern and western Europe and in the U.S.A. much naller gains in population are to be expected in the ext century than in the last. The large rise in birth-rates these countries since the war does not imply a trend wards larger families: the increase is mainly in first irths. In India, China, and elsewhere, the birth-rates nd death-rates are high, and western improvements sanitation and medical care may be expected to lower e death-rate before the birth-rate falls. These areas e potentially in the "swarming" stage, as England as at the time of the founding of her colonies. In the S.S.R. the position is intermediate: the death-rate as been materially reduced, but the birth-rate has llen to a lesser degree. Industrialisation of areas hich now live by manual labour will raise standards living, while further increase of population in these eas will tend to have the opposite effect. These problems would be simplified if the probable decline in deathtes could be accompanied by a greater decline in rth-rates. Simpler and less expensive methods of rth-control may come from the research programme the committee on human reproduction of the National esearch Council in Washington.

Dr. C. P. BLACKER classed population states into five stages: (1) the high stationary stage with a high death-rate and a high birth-rate; (2) the early expanding or "swarming" stage, when the death-rate is falling and the birth-rate still high; (3) the late expanding stage, in which the birth-rate is falling, but the death-rate falling faster (the U.S.S.R. is now in this phase); (4) the low stationary stage, when the net reproduction-rate is at unity; and (5) the declining phase. The crucial question is whether the nations can pass through stages 1, 2, and 3 to 4 without swarming and outstripping world food-supplies.

MIGRATION IN THE ADJUSTMENT OF POPULATIONS

Prof. T. H. DAVEY said that in the past migration had played an important part in adjusting national populations during expansion. France, on the other hand, has allowed immigration of foreign labourers to balance their excess of deaths over births. Nations in Blacker's second and third phases are liable to reach the population pressure which might seek relief in migration; and certainly urbanisation and emigration helped Great Britain to survive the rapid population expansion at the time of the industrial revolution. The overcrowded peoples of India, China, Japan, and the Dutch East Indies have no wide area of unused cultivable land. Of the appropriate countries to receive them only Australia and Canada have a stable population, and neither is willing to accept them. Moreover, though migration would reduce population in the sending countries for a time, the effect would be to reduce the death-rate and increase the rate of population growth until numbers were the same as before. In general, then, there is nothing to be hoped for from migration.

FAMILY PLANNING IN VARIOUS COUNTRIES

Dr. A. W. LANGEHEINE (Germany) said that before National Socialism family planning and marriage guidance were well advanced in Germany. In the early years of Hitler's rule contraceptives were still allowed but abortion was punished, and effective propaganda was used to encourage childbirth. Soon after 1939 a police order, later made law, forbade the use of contraceptives, and capital punishment was threatened for repeated abortion. These laws (capital punishment apart) have not yet been fully abolished, largely owing to the intervention of the Catholic countries, though general opinion is strongly in favour of their abolition. There has been a great increase in abortions; official figures of treated cases suggest a rate of 1 abortion for every live birth.

Dr. DURAND-WEVER recalled that in Germany in 1934 a secret order required soldiers to beget children wherever they could; and later the labour camps for young girls were deliberately put near those of the men. Since the capitulation of Germany marriage-guidance bureaus have been established throughout the Russian Zone in all the large cities, and 4 contraceptive clinics have been set up in Berlin. Abortion on therapeutic grounds is allowed.

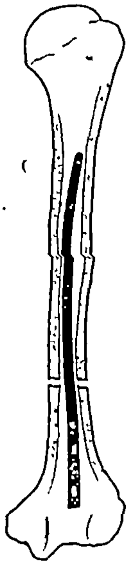
Lieut.-General KIN CHEUNG (China) said that there has never been an adequate census in China, but the population is thought to be some $463^{1}/_{2}$ million. If the standard of living is to be raised the population must be reduced. The only other way to increase national wealth is by industrialisation. Chinese intellectuals have been advising birth-control since 1919.

Dr. JEAN SUTTER (France) said that in France all contraceptive measures and propaganda are prohibited at present, on pain of fine or imprisonment. This attitude was nailed in the 4th week there was anatomical union after sequestrectomy. In a pathological fracture (carcinoma of bronchus) nailing brought about good function.

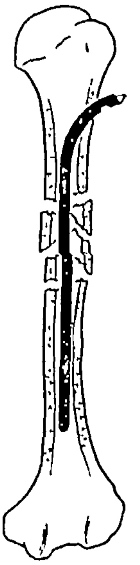
Radius and Ulna

The radius is nailed from the lower end, and the ulna from the upper end (fig. 6). The stability of this method of fixation offers great advantages here, but reduction may be difficult.

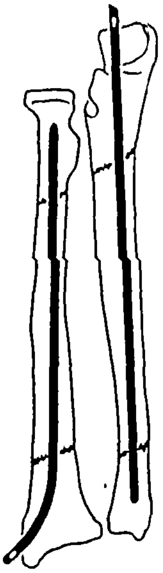
In 16 closed fractures open reduction had to be used in 6 cases (difficulties of reduction would be the same whatever the method of immobilisation). All united well except that of a workman who started heavy work 4 weeks after injury (without medical consent), broke the nail, and developed a pseudarthrosis of the ulna. This united after extraction of the nail fragments, freshening, and renailing.



(4)



(5)



(6)

Fig. 4—Fractured humerus nailed from below.

Fig. 5—Fractured humerus nailed from above.

Fig. 6—Fractured radius nailed from below, and fractured ulna nailed from above.

Nails were left in for at least 3 months.

Two compound fractures were nailed and united well; in one a defect of 4 cm. in the ulna was bridged by bone without grafting.

My impression is that the advantages derived from the early and anatomical union, and from the full joint and muscle function preserved throughout, outweigh the disadvantages, which are mainly the necessity for a moderate amount of apparatus and for screening. The dangers of sepsis and fat-embolism appear to be largely theoretical, and there is ample evidence that the nails have no adverse effect on bone or marrow.

I am, however, not competent to pass an opinion, and merely advocate that the method should be studied far more widely than appears to have been the case so far.

The accompanying figures are based on those of Küntscher and Maatz,[2] whose monograph should be consulted for further technical details.

---

2. Küntscher, G., Maatz, R. Technik der Marknagelung. Leipzig, 1945.

". . . Upon the limited soil of this planet we have to produce the food for an increasing population. There is no chance of importing supplies from Mars or the Moon. We might as well face the problem calmly and agree that we have of late years made an unholy mess of our solutions. The fault does not lie with the producers of food, who are a vast dispersed multitude of farmers and peasants. The fault lies rather with ourselves as social beings, in that we have given too little attention to what our scientists and economists were attempting to tell us. . . . We should by this time be thinking of food production and food distribution in the world as problems in good management; and many of our statesmen are obviously still thinking of them in terms of 19th century nationalism or imperialism."—F. LE GROS CLARK in *Feeding the Human Family*. London, 1948.

INTERNATIONAL CONGRESS ON POPULATION AND WORLD RESOURCE

THE International Congress on Population and W Resources in Relation to the Family, arranged by Family Planning Association, was held at Chelt from Aug. 23 to 27. Like the recent Mental H Congress this gathering ended its deliberations forming an international body. For the present takes the form of a provisional international commit to promote research and education in family planni with two representatives from each of the natio organisations in the U.S.A., Great Britain, Holland, Sweden, and such individuals from other countries they coöpt. The secretariat will be in London.

Sir JOHN BOYD ORR, F.R.S., opening the congr stated the crux of the discussion: if we cannot solve problem of world resources in this century, we heading for the greatest catastrophe in history. Bef the 1939–45 war two-thirds of the world populati were not fed, clothed, or housed up to a basic level necessity. The world population is increasing by million a year. Before 1939 it was 2000 million; the end of the century it will be 3000 million. To these people food production must be doubled wit the next 25 years. When standards of living rise, birth-rate falls; and the only way to get a static wo population is to raise the standard of living and edu tion. It was 150 years to the day, he said, since Malth published his famous pamphlet prophesying from over-population; but Malthus did not fore opening up of the southern hemisphere as a sourc food. Now we have no new hemispheres to rifle, much of our land is losing its fertility; dust bo have been created, and soil erosion means a fall reservoir of food resources. Some hold that it will be possible to provide food for all, but in Sir John C view if all cultivated land is brought up to the leve the best the same production will be possible with the acreage. Moreover it should be possible, by irriga and reafforestation, to recover land which has bee barren. We have not yet explored the resources timber, which can provide food, textiles, and essential commodities. Sir John believes we can and shelter the population likely to be achieved in next 150 years; and indeed that the total number world can feed is only limited by the amount of atten governments give to the problem. In the view Malthus, the excess population should be allowed to out; but he ignored the fact that people will not quietly. They will fight, as they were ready to d England in the hungry 'forties. We must have a w plan for food.

Dr. ABRAHAM STONE (U.S.A.) pointed out that far more food has always meant more population. improve food production is not enough: we must disseminate the means for family planning.

ESSENTIAL STANDARDS OF LIVING

Prof. FRANK LORIMER (U.S.A.) thought that to m it possible for another thousand million just to keep al would not make for peace. Malthus failed to allow the rôle of experimental science in raising food producti and for the effect of a rise in the standards of livi The more fortunate peoples—about a fifth of the worl population—were getting at the beginning of the war 2875 or more calories per person per day. Th included all the peoples of Western Europe, Austral New Zealand, and the American countries north the Rio Grande and south of Brazil and Cuba. Anot 30% of the world population—in southern and easte Europe, Soviet Russia, Brazil,

their work. They should rather ask why others have
led to undertake such a plain duty.

CURRENT RESEARCH

Dr. **Earl Engle** (U.S.A.) indicated some possible
es of research on semen. The spermatozoon emerges
m the testis with a complete store of energy, but
is also capable of metabolism. On an average,
) million spermatozoa must be present if an egg is
be fertilised. The state of the cervical plug of mucus
lso a factor in fertilisation. This mucus is hygroscopic,
l its state is under the control of œstrogens, so that
times it becomes more fluid and thus more readily
meable.

)r. **John Rock** (U.S.A.) favoured teaching young
ple family planning rather than encouraging them to
nk of the drawbacks of babies. Fertility is highest
the early years; and people are apt to use contra-
tives in these years and then to ask the gynæcologist
help them to get a child in the infertile years. In
.S.A. it is found that only people who have had
han 4 years of education replace themselves in the
generation; college graduates have not replaced
selves since 1860. One way of interfering with the
ductive cycle is to use hormones to stop ovulation
time.

of. **F. A. E. Crew**, F.R.S. said that fertility genes
lemonstrable in living forms other than man, and
an pedigrees suggest that they are present in man
Some genes are lethal and slay the individual
re he has time to reproduce. Hæmophilia, for
nple, kills the homozygous fœtus in utero, and
tens the life of the male. The higher the species,
the longer lived and the larger the animal, the
r the offspring. The human female is not well
ipped to produce more than four young in all;
from the child's point of view all the evidence
to show it is a bad business to be the first
d and a serious mistake to be the fifth, sixth, or
nth.

r. **Margaret Hadley Jackson** said that the
hasis at the congress had been on expanding popula-
s and diminishing food, and little had been said
ut the encouragement of families. We belong,
ever, to a country in which the curtain is about to
on the fourth act of Dr. Blacker's demographic
ma. It may be that a different method of approach
eeded in different areas of the world.

The congress urged the governments concerned to
e all possible steps to help the occupied countries to
establish their former organisations for planned
renthood.

In England Now

A Running Commentary by Peripatetic Correspondents

Any mug can wangle staphylomycin out of the Ministry for a pulmonary case, said our registrar. By the time you've read the third page of the patient's notes the tired bloke at the Whitehall end of the telephone more or less insists on sending you a month's supply. Of course, if its non-pulmonary you've got to give the Whitehall bloke some "cover," as he calls it—say that the patient is writing a personal stinker to the Minister, or that the *Daily Largesse* has offered to fly you the stuff forthwith. If the worst comes to the worst you can fall back on what was left over from the last case of meningitis.

What mugs these registrars must take us for, said the staphylomycin M.O.(supplies) moodily. By the time they reach the third page of notes on a case in which they obviously haven't done a bronchoscopy I usually chip in and say there's nothing doing until they have. Then the blackmail starts. Either the patient is writing a personal stinker to the Minister or else the *Daily Largesse* has been sniffing round. What sometimes does get my goat is the airy fairy way in which they finally say that they suppose after all they'll have to go to the black market for it as they do for their private patients.

* * *

Having duly warned the opposition that our team contained three schizophrenics and a manic, we lost the toss and went out to field. The game resembled cricket for the first ten minutes. Then one of our opening bowlers, having spent his morning in the depths of an insulin coma, had his usual hypoglycæmic reaction after the fourth ball of his second over. We were by now able to recognise the onset in the prodromal stages as the usual symptoms were ushered in by a succession of wide full tosses and long hops. These derived from his diplopia, and, while the sight of six stumps instead of three might have been expected to increase his confidence no end, they were unfortunately seldom seen as an even row but more often as two sets of three, one set being in line either with first slip's head or silly mid-on's feet. Twelfth man trotted out with a jug of glucose in time to avert the collapse of the bowler and the ruin of his analysis. Neither umpire could remember any rules applicable to such a complication, but after a lengthy argument it was decided to count the four balls as an over and resume from the other end. Two wickets promptly fell, one being that of the visiting captain, who complained bitterly and not unjustifiably about the mechanism of his defeat.

Our manic was wicket-keeper and had two habits which doubtless caused the late Dr. W. G. Grace much subterranean revolution. First, he never stopped talking throughout the match and many a batsman, through trying to follow the flight of ideas with his ears, failed to follow the flight of the ball with his eyes. Secondly, he appealed deafeningly for any ball that so much as touched a batsman, be it on belly, breast, or brow notwithstanding. Unnerving at the best of times, this technique was particularly successful now because our umpire at the other end was a passive homosexual midway through a course of electrical convulsion therapy. This masochistic little chap would rather die than hurt other people's feelings by disagreeing with them, and he raised his finger in dismissal if our manic so much as looked hopeful. Brisk rebuke and brief psychotherapy had to be administered to these respective gentlemen before the arrival of the next batsman. He, however, had been much unsettled before even reaching the crease, for as he passed cover-point that fieldsman whispered with intensity, "I know what you're thinking about me but you're wrong!" Consequently this batsman was too self-conscious to do anything but hit the first ball straight back into the bowler's hands.

This was the last incident for quite a time and things went almost normally till our turn came to bat. They had a very useful spin bowler, who was also, unfortunately, a very dusky West Indian. Number four in our batting list had embarked on his paranoid schizophrenia

---

"... We are assured by Dr. Ernest Jones that a constitu-
nal monarchy uses for the good of the State impulses and
dencies that are deeply buried within the human mind.
man beings crave for the protection of a lofty and conse-
ted parental figure. Their attitude towards this figure is
bivalent; but the constitutional system provides them
h the beloved good parent who is the sovereign, and the
ential scapegoat parent who is the Prime Minister. So far
Jones. Matriarchal rule goes one step further. It removes
possibility of rivalry towards the parental figure by
[illegible] on its behalf the need for maternal warmth and
[illegible] To translate this into everyday language: a female
r calls forth deeper loyalties and chivalrous devotions, it
dles in the subject a desire to defend and to protect,
ead of leaving him possessed with the sole desire of being
ended and protected."—G. J. Renier, *Manchester*
ardian, Aug. 30, 1948.

is governmental rather than ecclesiastic, and is called forth by the stationary population. England and Wales, Italy, and Germany are now following the demographic cycle in which France has been the pioneer.

Dr. G. NYCANDER (Sweden) said that the birth-rate reached its lowest point in his country in 1933, but has now recovered again. In 1946 abortion was legalised for conditions liable to endanger the health of the mother, and in cases of rape. In 1945 sex education was finally begun in schools.

Dr. P. A. VAN HUET (Holland) said that though the population of Holland had trebled in the last hundred years, and though the death-rate was the lowest in Europe, the Roman Catholic Church worked against contraception. There are legal penalties for publishing anything on the subject. Nevertheless centres have been opened and deal with both family planning and subfertility. In 1946 the Netherlands Society for Sexual Reform was founded, and has set up marriage schools for young people.

Dr. F. POLASEK (Czechoslovakia) noted that there has been a steady increase in the birth-rate of his country since the 1914–18 war. Government policy encourages this by tax remission, free antenatal and maternity care, priority in housing, and free medical treatment of infertility. There are no legal restrictions on contraception but the practice has never found much support. The government aims at a further increase of the birth-rate and the reduction of illegal abortion.

Dr. J. N. KHOSLA (India) said that the death-rate, though high (22 per 1000), has fallen. Polygamy, though permitted, is little practised, since women number only 93% of the men. He felt sure Indian women would respond as well as any other women to social change, but they have had very little sex education. Religion, he said, plays no part in the regulation of social affairs in India, but social customs do.

Prof. M. LANVAL (Belgium) observed that in his country birth-control was listed with things dubbed obscene; so anyone interested in family planning is now stigmatised at the outset. However, the law only prohibits the selling of contraceptives and the giving of contraceptive advice for profit, so doctors can give advice free—and appliances, too, if they can find a chemist who will sell them at face value.

Mr. F. M. MANSOUR (Egypt) gave two reasons for the large families of Egypt: as a sort of insurance (because infant-mortality is high and surviving children mean an easier old age); and as a hobby (because a family is a great source of interest and pleasure when there is not much other entertainment going). If the Egyptian population is to be restricted there must be a revolution in the means of production by industrialisation.

Dr. OKU AMPOFO (West Africa) said that at the start of the century his part of the world had emerged from the results of the slave-trade and was adjusting itself to European occupation. The native population in the Congo had been reduced by slavers from 8 million to 1 million. Commerce, however, has meant a change in the standard of living; and now children are becoming a liability because of the high cost of living and education. Feeling is tending towards small families and the abolition of polygamy.

BIRTH-CONTROL AND POPULATION

Dr. NILS NIELSEN (Sweden) said that birth-control alone cannot be responsible for the falling birth-rate in western Europe and elsewhere. Swedish population statistics, which date from the beginning of the 18 century, show a slowly declining death-rate an first a high birth-rate; later the birth-rate beg fall in the towns and afterwards in the country. 1910 the rate fell until the early 'thirties, since when has been a small but rapid rise. It is a common cu of the country not to marry until after the birth first child, and not always then—indeed, about ha adult population is unmarried—so the extram birth-rate is always high. Paradoxically, little control was taught until the birth-rate decline w full swing. Birth-control may be potentially dang to a race, but extreme limitation of family is cause economic factors and must be corrected by econ reform.

Dr. STONE talked of the remarkable change i U.S.A. since the time, 25–30 years ago, when Margaret Sanger started her campaign for family plan All the Churches have recognised the importan family planning for the stability of the family, th they may differ on methods. The law has been rede so that it no longer offers a barrier. The medical profe have recognised birth-control as a therapeutic mea and give instruction on it in the medical college 5 States birth-control advice is included in the pu health service, and it is hoped that in time such a will become a part of the Federal Public H Service.

Mrs. M. A. PYKE said that in Britain more tha the local authorities now give contraceptive advi any woman who needs it on medical grounds. It is h that in the end family planning will be an integr part of the public-health service, but for the pr it works well as a combination of voluntary and of effort. The Family Planning Association undert much research into contraception and subfertility.

Dr. S. CHAUDRASECCA (UNESCO) said that popul problems have always been a factor in causing UNESCO is starting research projects on populatio relation to various countries.

Miss MOYA WOODSIDE (U.S.A.) noted that in N Carolina there was a law allowing voluntary sterili on medical grounds for psychosis, epilepsy, and m defect. This is, in fact, being extended widely, unoffici to include women with large families.

ADVANTAGES OF FAMILY PLANNING

The Rev. JOSEPH MCCULLOCH said that contracep has only recently been rescued from evil associat Family planners, however, are only concerned those who oppose contraception for married pe These fear that mankind will end in race suicide, that birth-control encourages the pleasure principle irresponsibility. Such views are based on an unc promising estimate of man's unredeemed nature. Fa planning must be taught as a true fulfilment i personal relationship. The way of redemption is raising of the individual level of moral responsibi Man is born to know more and more what he doing.

Mr. KENNETH WALKER, F.R.C.S., remarked that fa planning relieves the mother of the danger to health life produced by an uninterrupted series of pregnan It is preposterous to suggest that the chief motive spacing a family is a desire for luxury. Fear of imp nating his wife, when the family is already as larg he can afford, may make a man impotent.

Dr. C. VAN EMDE BOAS (Holland) wondered why fa planners were always relieved to hear an ethical defe aminers, and the 4th (who was a "borderline pass" the part 1 examination) has now withdrawn from the dical school.

All students who failed in their first attempt at the rt 1 examination and who received between 45% 149% of the marks passed the part 1 referred examinan. but subsequently had difficulty with the part 2 mination. Those who failed part 2 on their first empts succeeded, however. on the second. All our ntual failures came from the group who did not get % in their first attempt at part I. Those of this group o ultimately succeeded in passing part 2 did so by a y narrow margin.

Of the original 83 students who commenced the egrated curriculum in anatomy and physiology. 70 re therefore moved on to the fourth year of the dical course: 9 were referred in examinations, 2 have hdrawn of their own accord, and 2. who were away ause of illness, have fallen back a year.

The high correlation in the showing of students in t 1 of the examination, which is mainly topographical emphasis, with that in part 2, which is mainly physioical. is interesting. We should like to think that it is. least in part. attributable to the close integration of tomical and physiological teaching throughout the rse.

LATENT TETANY CAUSED BY BAL

SIR,—The article by Dr. Russell and colleagues ly 31) calls for some comment as the authors' conson that "all the symptoms of toxicity from BAL capable of explanation as latent tetany" is hardly stantiated by the reported facts. The symptoms of ent tetany are not reliable diagnostic criteria. They variable and may simulate a number of other condins such as anxiety state, asthma, hysteria, and lepsy. Also, if a patient in latent tetany develops mps he almost invariably develops some degree of popedal spasm, and this was not specifically mentioned having been seen by the authors. Furthermore, the of symptoms noted with BAL intoxication includes ms which are very rare in latent tetany—e.g., miting, and a burning sensation or pain in the eyes, se, mouth, and throat. Tingling or numbness is the re typical symptom of latent tetany. Severe abdominal in does not occur except in gross tetany with definite popedal spasm.

The fact that Trousseau's sign was negative except one instance is also contrary to what one would expect latent tetany. Indeed, the single positive response t of thirteen subjects is what might be found with y group of young adults who are physically upset by e injection and collection of blood. It is also unwise base a diagnosis of latent tetany on Chvostek's sign; 72% of hypocalcæmic adults it was negative,[1] while raham and Andersen[2] have condemned it as a phenoenon unrelated to tetany. From my recent experience the press) it seems reasonably reliable in the acute tanies such as Dr. Russell and colleagues were studying. must be accepted with precautions, and the degree of sponse should be recorded in some accepted classificaon such as that of Frankl-Hochwart. Lastly, the study electrical excitability is not in agreement with the gnosis of latent tetany.

These criticisms are offered with the feeling that the pothesis is not established and yet is not necessarily se. Indeed it should be easy to decide the issue by ing BAL plus constant intravenous calcium gluconate; d also by producing experimental hyperventilation any[3] in the subjects later and comparing the symptoms with those of BAL intoxication. If the existence of tetany with BAL intoxication is established the cause must be sought in the usual places first. The patient whose case was recorded by Dr. Russell complained of vomiting and profuse sweating. and may well have been hyperventilated. The single estimation of alkali reserve done some days after the last BAL injection does not disprove the possibility of alkalosis tetany.

Dublin. D. K. O'DONOVAN.

SMALLER AND BETTER PRACTICES

SIR.—Your leading article of Aug. 14 is very much to the point. General practice is in danger of being swamped by a tidal wave of patients requiring attention. Many items are trivial and can be attended to by a good secretary with some first-aid training. There are the requests for corsets. glasses, milk, drug repeats, and miscellaneous certificates; there are continuation dressings and routine injections. Perhaps a short account of a partnership in an urban and rural district which is organised to produce the maximum medical efficiency and to avoid all non-medical and trivial tasks would help others confronted by new threats to their standards of medicine.

My partner and I have about 4000 patients between us. We cover an area of 60 square miles and we motor about 1200 miles a month on our rounds. We work 12–14 hours daily and allow ourselves one half-day a week and two Sundays in a month free of calls or other duties. Our secretary is busy from 10 A.M. until 7 or 8 P.M. We hold surgeries three times daily at the urban centre and twice weekly at two rural centres. But these surgeries are performed by one of us only, in a fixed and equal rota. In this way all our patients are assured of seeing either of us at one or more surgeries every day at the centre and once weekly in the two rural surgeries. They all know which of us will be on duty at any particular surgery, and if in doubt can inquire from our secretary. This member of the team is most essential and acts as a screen to shield us from trivial tasks and wasted time.

Our nearest laboratory is 15 miles away. X-ray facilities and the county hospital are 30 miles away. There are no medical consultants of the first degree nearer than 70 miles away. Consequently we try to be comprehensive and only send cases away for very complicated investigations and for surgical treatment. In order to undertake proper medical diagnosis we find the following equipment is necessary:

1. A microscope and bacteriological stains for blood-smears, sputum tests, and centrifuged deposits of urine.
2. Apparatus for accurate hæmoglobin estimations (Sahli's for domiciliary use and Haldane's for surgery use); hæmatocytometer tubes for red and white cell counts; special stains for reticulocyte counts.
3. A Westergren blood-sedimentation tube.
4. Gerrard's ureometer for urea-clearance and urea-concentration tests of renal function.
5. An X-ray apparatus with a fluorescent screen for assisting in the diagnosis of heart, lung, and gastric disease, for the treatment of fractures, and for the assessment of injuries and diseases of joints. We have found many new cases of tuberculosis in this way, and have been able to reassure many patients of the absence of pulmonary or cardiac disease. All cases presenting doubtful X-ray appearances are naturally referred to an appropriate specialist.

A good secretary can take routine X-ray films and develop them. She can do blood-counts and test urines. She controls the internal telephone exchange and deals with all incoming messages at her discretion, passing some on to our private residences or surgery, or simply taking action without bothering us. In this capacity she contacts specialists, house-surgeons, and colleagues by telephone, and saves us hours of waiting on the line.

We use a consulting-room and a separate smaller examination-room, so that any patient requiring a complete examination can be by-passed to the latter without interrupting the surgery circulation. The consulting-room also has a completely screened-off couch for full examinations. By these methods two patients can be seen at once in little more time than it takes to chat about the weather and the news to one patient dealt with by the "bottle-of-medicine" in West Africa with beliefs, supposedly false, that the darkies were depriving him of his virility by means of witchcraft. Now he complained that this Sambo was making meaningful faces at him in the course of his run-up. He also suspected that the ball had been rendered radioactive—certainly a novel, if improbable, adjunct to any bowler's armoury.

Logic did not prevail: number four stalked off the field and was entered in the score book, after another conference, as "retired hurt." This apt suggestion came from the opposing captain, who now seemed, much to our relief, to be entering into the spirit of the thing. Even so, it was perhaps as well we lost by 40 runs.

* * *

When my friend the physiologist proposed that we should go and watch the Olympic weight-lifting, I responded with negative enthusiasm. Why, when the world is so full of a number of things, why choose weight-lifting? But his ardent pursuit of any and every phenomenon of the physical universe is infectious as well as enviable. So in due course we took our seats, armed cap-à-pie—he with an enormous pair of binoculars and I with a pencil and the back of my ticket (for working out averages and standard deviations and all that: la science, toujours la science!).

Why are negroes so successful in athletics? The physiologist speculated on the advantages of a less excessively developed cortical control, and referred me to the shorter reaction times that have been observed with left-hand responses; presumably the cortex leaves the left hand to its own devices a little more than the right. As he said, you can have a manager or a second to do any preliminary planning that may be necessary; when the gong sounds it is best to be a complete blank from the basal ganglia upwards, to avoid any "psychopathology of everyday life." Perhaps it would have been possible to estimate the I.Q. of the competitors from their idiosyncrasies when they mounted the stage. One man invariably plodded backwards and forwards across the back of the stage several times, then marched up to the bar, grasped it—and then straightened up again. The suspense was terrible. Another always stood over the bar for 38 seconds (average), apparently in deepest thought (possibly self-hypnotism). Others adjusted the bar to exact parallelism with the front of the stage. None took less than 3 seconds over these preliminaries, the mean being 10·65 seconds. My ticket was too small for me to work out the standard deviation, but I don't suppose you care. Also—I nearly forgot—weights were lifted, phenomenal weights. Given the necessary muscle, the great thing here is coördination, particularly in the way of balance; it doesn't do to topple when you are supporting the equivalent of two 12-stone men. Many resounding thuds testified to this. Finally, I must spare a word for the three judges, who gave their decisions, often on subtle technical points, almost before the bar had reached the floor—not always to the satisfaction of the spectators, who were not diffident in expressing their own opinions. Altogether, a good time was had by all, including the two scientists.

* * *

Most doctors seem to be feeling frustrated over the question of new cars just now; but few can have experienced the refinements of torture suffered by myself, a poor struggling assistant in the suburbs of Coventry. As I bounce (literally) along the streets, most of which appear still to be suffering from the effects of the blitz, while my poor 1935 Morris "8" rattles with loose bodies in every joint, agony piles on agony as a succession of new Jaguars rolls by on test (I did experience a certain thrill at seeing one of the breed speeding along a nearby country road with test-plates and left-hand drive). Humbers, Hillmans, Standards, and Triumphs, all shining new, seem to be posted at strategic points along every road expressly to make my torture worse. At really bad moments I go along and park outside the Riley works and gaze wistfully at the new models in the yard. I have one slight consolation. By the time I can afford a new car the shining beauties I see today may all be going second-hand for a mere twenty pounds or so.

Letters to the Editor

INTEGRATION OF ANATOMY AND

SIR,—A year ago you published a letter[1] rec the results of the first examination taken in th grated curriculum for anatomy and physiology Birmingham University instituted in 1946. Th liminary information was submitted in response request from one of your correspondents, and we took to add to it, as we can now do, after the part of the course had been completed. As some has elapsed since our last note on the subject, it be advisable in the first place to outline the innovations of the Birmingham curriculum. They

1. To combine the anatomical and physiological in every course of lectures, and to avoid separate in the two "subjects."
2. By divesting the subject of much unwieldy, and pr unnecessary, detail, to confine dissecting-room to three instead of five terms.
3. To devote the anatomical teaching of the fourt fifth terms to surface and radiographic anatomy neurology.
4. To divide the 2nd M.B. examination into a first dealing with topographical anatomy and h taken at the end of the third term, and a second dealing mainly with physiology and functional ar

In October, 1946, the first integrated course was by 83 medical students. In the following June 81 the part 1 examination and 58 (about 70%) pa 22 out of the 23 who failed, and one of 2 students had been absent from the course because of prepared for the referred part 1 examinati September, 1947, when 21 presented themselve examination and 14 were passed. The 7 who failed asked to withdraw from the school.

The 72 students who had completed the part 1 tion took the courses of the fourth and fifth terms o curriculum, which, in addition to the usual classes in physiology and biochemistry, included classes in neurology, surface anatomy, and All sat the 2nd M.B. part 2 examination in March o year. The examination comprised two written one of which included three questions of a morpho nature. Practical examinations were held in bic in experimental physiology, and in anatomy. anatomy examination, which was in the form of voce, not only covered those aspects of anatomy had been actively taught in the fourth and fifth but also attempted to discover how much topographical anatomy had been retained by the The standard of the whole part 2 examination least as high as the usual 2nd M.B. examination. but 10 of the 72 candidates satisfied the The 10 who failed were allowed to sit a referred examination in June, when all but 2 passed.

We were agreeably surprised to discover a high stan of retention of topographical knowledge, and, so f the anatomical aspect of the integrated course is cerned, we are satisfied that the students who now completed the course have at least as good a k ledge of topographical anatomy as is usually dema from 2nd M.B. candidates. We are also confident their familiarity with neurology is greater than is u in 2nd M.B. students.

The whole course has permitted two separate ev tions of all students under full examination conditi and in the case of those who failed either the pa or part 2 examination (or both) three or four. possible, therefore, to derive certain further inf about performance and about the likelihood th student's showing in the part 1 examination is indication of his probable results in part 2. All candidates who achieved a mark of 55% and ove part 1 passed in their first attempt at part 2. O who obtained between 50% and 54% in part 1, passed in their first attempt at part 2. The 4 who sat the part 2 referred examination; 3 satisfied he treatment of a number of young persons with disease "in succession." It is just these early which respond well to a strict and prolonged ıe of bed rest, with or without associated collapse py. It is apparent from the average type of case tted to hospital or sanatorium that not all physicians with Dr. Stradling's selection of cases; in fact, mes one wonders if the available beds are not dered by some to be for the use of the homeless and able. We do not think the bed position would be ly improved by giving the chest-clinic physician ect control" of all beds. We think the answer n closer coöperation between the hospital and sana- m physician on the one hand, and the clinic physician ne other. Let the first have his outpatient depart- where he can see old and new cases, diagnose. , and follow them up, and let the clinic physician beds in hospitals. It is impossible to expect the physician to undertake the care of more beds and act as consultant and specialist for a population of arter of a million or more, often spread over wide ; our Scandinavian colleagues usually serve an containing a population of about 60,000, and no ment is undertaken by the clinic. By handing some of the outpatient work to the sanatorium ı, the clinic physician could ease the burden upon elf, although a much greater number of physicians be needed to work an efficient service.

---

[1] Boyd, J. D., Smout, C. F. V., Zuckerman, S. Lancet, 11, 150.

here is no doubt that the centrally administered ing-list causes too much separation between the physician and chest hospital. Much could be to improve this position and make coöperation more ticable if chest hospitals were affiliated to nearby ics. Cases could then be referred direct to the pital covering the area, and the more direct contact ld offer a chance of real coöperation between chest pital and chest clinic.

it not time that cases requiring major thoracic ery came under the personal preoperative and post- ative supervision of a surgical team with its own and waiting-list? The clinic and sanatorium sician would each consult freely with the surgeon, would then decide the relative urgency and optimum e for operation in each case. Few surgeons would gree that it would be wise to have a physician of erience attached to each surgical team for day-to- consultations. We feel certain that in this way ter use would be made of beds, and a better service rded to our patients.

inally, it should be obvious that any suggestions for rcoming the present lack of beds by lowering the ndard of nursing and medical treatment, are to be recated as a long-term policy. The remedy lies mately in taking whatever steps are necessary to edy the nursing shortage.

B. J. DOUGLAS SMITH
C. J. STEWART

olindale Hospital,
London, N.W.9.

SIR,—The magnitude of the problem created by the ortage of beds for patients with pulmonary tuber- losis is indicated by the frequency with which this estion is discussed in your journal. Waiting-lists are long as ever. Until more beds are available, the est physician must use the beds at his disposal so that many patients as possible receive treatment in the ortest possible time. One of the means to this end is a astic reduction of stay at the sanatorium before and er collapse therapy, careful consideration having been en to all the relevant factors, including home nditions.

Collapse treatment in the patient's home can play an portant part in shortening the waiting-list, as has eady been observed.[1] It can be started in the home not ly in cases with minimal disease but also, without undue , where the disease is moderately advanced, whether ilateral or bilateral, especially when the patient's erves seem nearly exhausted. A few weeks or months preliminary rest in bed will point the way to be lowed in treatment. The patient with bilateral ease still suitable for collapse therapy can have at least one pneumothorax successfully established while waiting for admission; once admitted, if in need of major surgery for his other lung, he may need only a short spell for detailed investigation before he is ready for operation.

Perhaps the greatest difficulty in carrying out domiciliary collapse therapy lies in picking the right type of patient. So far, I have done about 30 inductions in patients' homes. Among the criteria I consider of major importance are: the X-ray appearance, the patient's attitude to the prospect of protracted rest in bed, his temperament, and finally the home conditions. The X-ray appearance should be such that the success of collapse therapy appears probable: and before induction the patient must have stayed in bed for at least 1–2 months. To check on this, I usually visit the house a few times without previous warning; generally speaking, the patient must be a "collaborator." At his home the patient should have at least somebody in the house to prepare his meals and be at hand. Sympathetic guidance may often help to create more tolerable conditions in the house.

The success of any treatment depends materially on the patient's morale, especially when treatment is lengthy. Now that the value of collapse therapy is generally known, it is difficult to persuade a patient that all he needs is rest in bed at home for 6 months or longer. Treated in this way, his morale may have vanished long before he is admitted to sanatorium—and with it his prospect of a favourable prognosis. We are all agreed that the ideal place for this therapy is the sanatorium, but while reaching for the desirable we must not by-pass the attainable. The acceptance of Dr. Stradling's suggestion regarding continuity of treatment would foster domiciliary collapse treatment.

City of Leeds Health Clinic. HERMANN GRUNWALD.

MEDICAL USES OF POLYTHENE

SIR,—Let me congratulate Dr. Farquhar and Dr. Lewis (Aug. 14) on their description of a technique which is, as they claim, a definite advance in intravenous therapy. Ureteric catheters have, of course, been used in somewhat similar fashion for many years with varying degrees of success. I would be interested to know what means they adopted, apart from splintage of the proximal flexures, to prevent the normal posture of flexion of the infant, particularly in the arms, stopping the flow of fluids by kinking the veins.

However, before Bateman's and similar cannulæ are discarded one might point out that very successful intravenous therapy is possible with them; in the gastro-enteritis unit at this hospital many "cut-downs" have lasted for seven days or more with minimal phlebitis, and one, regarded as somewhat of a record, ran for fourteen days with very little venous reaction.

That the elimination of trauma to the vein, apart from the initial insertion, is important is well shown by the readiness with which a phlebitis will occur in a restless infant, as distinct from the placid or flaccid one. Other factors are of considerable import, such as the substances used for transfusion or infusion and the avoidance of unnecessary interference and infection; but I have always been impressed by the need for adequate and secure splintage, and for sedation of the very restless infant when rigid cannulæ are used. The flexible catheter reduces this factor to a minimum.

My main object, however, is to plead for a more general adoption of a technique which appears to be the routine in most trans-Atlantic units and in some Continental ones—that of direct venepuncture. The success with which this method is practised depends mainly on the environment and the enthusiasm with which it is fostered. Following the advent of a Canadian lady for a tour of duty on our gastro-enteritis unit, for some months over 50% of all intravenous infusions were done by this technique. As an example, one infant, the severity of whose illness necessitated continuous intravenous therapy for 28 days, left hospital with only one "cut-down" scar. One of these "stab" drips has run for nine days, at an average rate of a litre daily, taking various fluids including 5% glucose, Darrow's solution, blood, and plasma. For the actual venepuncture, selected hypodermic or small intramuscular needles can be used;

Maclean, A., Gemmill, J. S. *Lancet*, 1948, i, 173. Pritchard, F. K. *Ibid*, p. 302. Stradling, P. *Ibid*, Aug. 21, p. 311.

technique. The examination-room is invaluable for fluorescent screening, ophthalmoscopy, antrum illumination, and any dark-room technique. It is also used for minor dressings, routine injections, and antenatal supervision.

We are both fully occupied with our patients' health and welfare, and we try to give them comprehensive medical supervision. We are doubtful if we can achieve a sufficient income under the N.H.S. for such an expensive outlay and service. We are faced with the possibility of having to reduce our standards of practice unless the Government are willing to recognise the financial strangulation of smaller practices. Yet better medicine can only be done with a smaller list.

Grange-over-Sands. P. D. MULKERN.

SIR,—Having read your recent leading article (Aug. 14) on the maintenance and improvement of the standard of general medical practice, may I point out another major aspect of the N.H.S. which militates against this? Every improvement in facilities—every instrument or apparatus that is now acquired by a general practitioner—is a financial loss. He cannot charge his patients even a small fee to cover the actual cost of it. If he does not provide any improvements his income will remain much the same. There appears no incentive, except the doctor's pride in his work, to provide more than routine treatment. In fact financial loss loads the balance against any display of initiative.

Burley, Hants. P. R. G. HOWARD.

ARTIFICIAL INSEMINATION

SIR,—At the risk of appearing unduly sensitive, I am requesting you to allow me to reply to certain criticisms in the report of the Archbishop of Canterbury's Commission on Artificial Insemination[1] bearing upon a memorandum issued by the Medical Defence Union.

The union's memorandum did not purport to be an exhaustive study of the subject from all angles, and this the union had neither the facilities nor the intention to undertake. It was written, as the headnote states, solely with a view to the protection of practitioners who engage in the practice of artificial insemination. In these circumstances the criticism that the memorandum is "superficial" is entirely unjustified.

It is, moreover, stated that the memorandum is "grossly misleading," but no indication is given of the reason for such strong language. The chapter of the report dealing with the legal aspects of artificial insemination fails to reveal any basis for the criticism, unless it be that the writers have confusedly attributed to the union the authorship of an article in a medical journal[2] or assumed that the union shared the views expressed in that article. Should this be so, it is appropriate now to repudiate on the council's behalf both the authorship of the article, and agreement with the views therein expressed.

It is conceded, of course, that the union's memorandum did not make reference to the difficulty that will arise over the registration of the birth of an infant resulting from artificial-insemination donation, since registration is not a matter with which the practitioner is normally concerned. The difficulty is a very real one, and to it further consideration will be given by my council in the future; for this constructive criticism we are grateful.

It is regrettable that the authors of the chapter in question should have thought it proper to publish strong condemnation of the views expressed by the union in a matter of complexity and public importance without first giving to the union some indication of their intention and an opportunity of expounding its views. The very eminence of the authors in their own field promotes an expectation that the usual courtesies would have been observed.

It should further be noted that permission to publish the union's memorandum as an appendix to the report was only sought when the report itself was in galley proof and at a time when the urgency of publishing the report precluded the union from properly considering whether the memorandum—prepared, as it was, with a different object in view—was suitable for such p I add with regret that neither then nor at any time was there any communication to the union th memorandum was or would be made the subje criticism.

Except for the single matter mentioned above, appears at present no need for the union to mo any way the advice to its members set out in memorandum.

Secretary, Medical Defence

BEDS FOR PULMONARY TUBERCULOSIS

SIR,—In his letter of Aug. 7, Dr. Tattersall the problem of making 15–25 beds serve the needs population of 110,000 with a tuberculosis death- 60–70 per 100,000. It would not be surprising if in a situation his motives were to become somewhat Should he regard tuberculosis as an individual prob In this case every patient, regardless of the exte his disease on diagnosis, would be equally entitled treatment bed. Should his chief concern be the infectivity of his patient? In this case segregation even the most risky form of treatment might be able. Should he be concerned with the wider problems affecting the tuberculous family? In thi the middle-aged breadwinner with relatively ex disease should have priority over the young with the minimal lesion. Some light may be thro Dr. Tattersall's dilemma by reference to Wickste "Administration of Resources and Choice be Alternatives."[1] At the present time his is perhaps influenced by his belief in the efficacy of collapse therapy, and he claims that he has ren 30% of his infectious cases "safe" by these though "their ultimate fate is undetermined."

The correspondence which has followed Dr. Ben article illustrates the extremities of medical improv to which we are driven by the inadequacy of th accommodation for the tuberculous. Surely we abandon the pretence that a brief admission to a make some adjustment in the respiratory mech can exert a lasting influence on a disease with complicated ætiology as pulmonary tuberculosis. patient himself requires long and careful handling the "crash A.P." for the early lesion is more often not a disastrous measure. The introduction of st mycin will further complicate therapy, and will an even nicer judgment in timing surgical interve

Some facts in the situation cannot be disp pulmonary tuberculosis is the greatest destroyer of adult life; it presents an immense social problem given time and opportunity treatment can be efficacious. Can these things be said of many conditions which secure admission to the medica surgical wards of general hospitals? It is surely t say that on the medical wards of a general hospit average age is nearer 60 than 20, and the patients suffer from intractable and untreatable diseases. the main nursing effort of the country is concentrat this relatively unpromising material, to the disadva of urgent and treatable cases of young adult phthi

It is an interesting thought that if each of the g hospitals in this region were to second one nurse three months, for special duties and training, to the hospital from which this letter is written, it wou possible to open at once the beds which are now through lack of nursing staff. The present wa admission is nine months.

County Hospital, Harefield, Middlesex. L. E. HOUGH

SIR,—The letters of Dr. Tattersall (Aug. 7) an Stradling (Aug. 21) both put forward useful sugge for overcoming, at least partially, the difficult finding suitable accommodation for the tuber patient. Particularly valuable is Dr. Strad suggestion for the reallocation of hospital beds in ge so that more can be devoted to the treatment of the tuberculous adult.

Some of his views, however, are more debata for instance, it seems doubtful whether the beds used for the treatment of the chronic case could be the treatment of a number of young persons with disease "in succession." It is just these early which respond well to a strict and prolonged ne of bed rest, with or without associated collapse apy. It is apparent from the average type of case itted to hospital or sanatorium that not all physicians e with Dr. Stradling's selection of cases; in fact, imes one wonders if the available beds are not idered by some to be for the use of the homeless and rable. We do not think the bed position would be tly improved by giving the chest-clinic physician ect control" of all beds. We think the answer n closer coöperation between the hospital and sanam physician on the one hand, and the clinic physician he other. Let the first have his outpatient departt where he can see old and new cases, diagnose. , and follow them up, and let the clinic physician beds in hospitals. It is impossible to expect the c physician to undertake the care of more beds and act as consultant and specialist for a population of rarter of a million or more, often spread over wide s; our Scandinavian colleagues usually serve an containing a population of about 60.000, and no tment is undertaken by the clinic. By handing some of the outpatient work to the sanatorium , the clinic physician could ease the burden upon elf, although a much greater number of physicians be needed to work an efficient service.

---

[2] Barton, M., Walker, K., Wiesner, B. P. *Brit. med. J.* 1945, 1, 40.

[1] Wicksteed, P. H. Common Sense of Political Economy. Lo

here is no doubt that the centrally administered ing-list causes too much separation between the c physician and chest hospital. Much could be to improve this position and make coöperation more ticable if chest hospitals were affiliated to nearby ks. Cases could then be referred direct to the ital covering the area, and the more direct contact ld offer a chance of real coöperation between chest ital and chest clinic.

it not time that cases requiring major thoracic ery came under the personal preoperative and postative supervision of a surgical team with its own s and waiting-list? The clinic and sanatorium sician would each consult freely with the surgeon, would then decide the relative urgency and optimum for operation in each case. Few surgeons would gree that it would be wise to have a physician of erience attached to each surgical team for day-to- consultations. We feel certain that in this way ter use would be made of beds, and a better service rded to our patients.

inally, it should be obvious that any suggestions for rcoming the present lack of beds by lowering the ndard of nursing and medical treatment, are to be recated as a long-term policy. The remedy lies imately in taking whatever steps are necessary to edy the nursing shortage.

B. J. DOUGLAS SMITH
C. J. STEWART
W. E. SNELL.

olindale Hospital,
London, N.W.9.

SIR,—The magnitude of the problem created by the ortage of beds for patients with pulmonary tuberlosis is indicated by the frequency with which this estion is discussed in your journal. Waiting-lists are long as ever. Until more beds are available, the est physician must use the beds at his disposal so that many patients as possible receive treatment in the ortest possible time. One of the means to this end is a astic reduction of stay at the sanatorium before and ter collapse therapy, careful consideration having been ven to all the relevant factors, including home nditions.

Collapse treatment in the patient's home can play an portant part in shortening the waiting-list, as has ready been observed.[1] It can be started in the home not ly in cases with minimal disease but also, without undue k, where the disease is moderately advanced, whether ilateral or bilateral, especially when the patient's erves seem nearly exhausted. A few weeks or months preliminary rest in bed will point the way to be llowed in treatment. The patient with bilateral sease still suitable for collapse therapy can have at least one pneumothorax successfully established while waiting for admission: once admitted, if in need of major surgery for his other lung, he may need only a short spell for detailed investigation before he is ready for operation.

Perhaps the greatest difficulty in carrying out domiciliary collapse therapy lies in picking the right type of patient. So far, I have done about 30 inductions in patients' homes. Among the criteria I consider of major importance are: the X-ray appearance, the patient's attitude to the prospect of protracted rest in bed, his temperament, and finally the home conditions. The X-ray appearance should be such that the success of collapse therapy appears probable: and before induction the patient must have stayed in bed for at least 1–2 months. To check on this, I usually visit the house a few times without previous warning; generally speaking, the patient must be a "collaborator." At his home the patient should have at least somebody in the house to prepare his meals and be at hand. Sympathetic guidance may often help to create more tolerable conditions in the house.

The success of any treatment depends materially on the patient's morale, especially when treatment is lengthy. Now that the value of collapse therapy is generally known, it is difficult to persuade a patient that all he needs is rest in bed at home for 6 months or longer. Treated in this way, his morale may have vanished long before he is admitted to sanatorium—and with it his prospect of a favourable prognosis. We are all agreed that the ideal place for this therapy is the sanatorium, but while reaching for the desirable we must not by-pass the attainable. The acceptance of Dr. Stradling's suggestion regarding continuity of treatment would foster domiciliary collapse treatment.

City of Leeds Health Clinic. HERMANN GRUNWALD.

MEDICAL USES OF POLYTHENE

SIR,—Let me congratulate Dr. Farquhar and Dr. Lewis (Aug. 14) on their description of a technique which is, as they claim, a definite advance in intravenous therapy. Ureteric catheters have, of course, been used in somewhat similar fashion for many years with varying degrees of success. I would be interested to know what means they adopted, apart from splintage of the proximal flexures, to prevent the normal posture of flexion of the infant, particularly in the arms, stopping the flow of fluids by kinking the veins.

However, before Bateman's and similar cannulæ are discarded one might point out that very successful intravenous therapy is possible with them; in the gastroenteritis unit at this hospital many "cut-downs" have lasted for seven days or more with minimal phlebitis, and one, regarded as somewhat of a record, ran for fourteen days with very little venous reaction.

That the elimination of trauma to the vein, apart from the initial insertion, is important is well shown by the readiness with which a phlebitis will occur in a restless infant, as distinct from the placid or flaccid one. Other factors are of considerable import, such as the substances used for transfusion or infusion and the avoidance of unnecessary interference and infection; but I have always been impressed by the need for adequate and secure splintage, and for sedation of the very restless infant when rigid cannulæ are used. The flexible catheter reduces this factor to a minimum.

My main object, however, is to plead for a more general adoption of a technique which appears to be the routine in most trans-Atlantic units and in some Continental ones—that of direct venepuncture. The success with which this method is practised depends mainly on the environment and the enthusiasm with which it is fostered. Following the advent of a Canadian lady for a tour of duty on our gastro-enteritis unit, for some months over 50% of all intravenous infusions were done by this technique. As an example, one infant, the severity of whose illness necessitated continuous intravenous therapy for 28 days, left hospital with only one "cut-down" scar. One of these "stab" drips has run for nine days, at an average rate of a litre daily, taking various fluids including 5% glucose, Darrow's solution, blood, and plasma. For the actual venepuncture, selected hypodermic or small intramuscular needles can be used;

short-bevel needles are better retained in the vein but are often difficult to insert. The Frankis Evans type of double needle has particular advantages. The veins of election are those of the dorsum of the hand and foot, but the radial, antecubital, and long saphenous veins can occasionally be used in an infant without much adipose tissue. Adiposity is the biggest obstacle to successful venepuncture as the vein cannot then be readily seen or palpated. The largest needle that can successfully be inserted in the vein is naturally the one of choice. The method of securing the needle and of splintage are of great importance. The main advantages of this technique are that the vein more readily re-canalises; there is much less phlebitis and periphlebitis; wound infection cannot occur since there is only a needle puncture; no scar results; and veins which may be of vital value to an infant can be spared.

Finally, I cannot agree with the writer of the section on intravenous therapy in a recent pædiatric textbook that "it is practically always necessary to cut down on the vein in children younger than five years." Surely we should make it an accepted principle in our pædiatric units that direct venepuncture is the method of choice in every child unless there are definite reasons to the contrary.

Queen Elizabeth Hospital for Children,
London, E.2.
B. McNicholl.

SIR,—With reference to the most interesting article by Dr. Farquhar and Dr. Lewis, for some time I have used polythene tubing in the treatment of varicose veins, inserting it up the saphenous vein after doing an "ankle tie." It has just the right resistance and it is far more practical and very much cheaper than ureteric catheters, which require special sterilisation and deteriorate rapidly after being used once or twice.

London, W.1.
R. Rowden Foote.

PROFESSIONAL SECRECY AND VENEREAL DISEASE

SIR,—I write in support of Sir Ernest Graham-Little and Miss Hardwick (Aug. 14). I am confident that the promise of secrecy, contained in the original V.D. scheme, encouraged patients to attend a clinic and—of equal importance—to continue under treatment. The original scheme, which resulted from Sir Malcolm Morris's energetic campaign, produced a steady decrease in the incidence of syphilis throughout the inter-war years; the L.C.C. returns record 8118 new cases in 1921 and only 2864 in 1938. It would be lamentable if such progress should be jeopardised by the new decree. Nor should we forget the honourable tradition of our profession, not to divulge what we see and hear in connexion with our professional practice.

London, W.1.
Henry MacCormac.

SALARIES IN GOVERNMENT SERVICE

SIR,—The Spens report on the remuneration of specialists and other whole-time hospital medical officers suggested that clinical work should be remunerated more fairly than in the past when higher salaries meant diversion to administrative work.

The Ministry of Pensions has reviewed the salaries of hospital medical officers and has just notified them individually of the new scales. The notification received by me does not indicate whether any increments will be allowed in future years. Nor has any provision been made for superannuation, for the Ministry stays out of the National Health Service and is not bound to accept the principles of the Spens report.

I have been employed for some years at the maximum rate of £550 per annum (plus £100 living-out allowance and £90 consolidation allowance, making a total of £740). I have reached this by annual increments (which had to be requested) from the starting salary of £350, and was informed on application in recent years that the Ministry did "not usually pay more." My new salary has been consolidated at £890 per annum.

This information may enable hospital medical officers not employed by the Ministry of Pensions to obtain some idea of their new salaries.

"Temporary" Medical Officer.

THE ALCOHOLIC

SIR,—It was instructive to read how your contri (Aug. 7) broke away from alcohol with the aid of holics Anonymous. Yet, few addicts are capable performing such a feat unless medicine has paved way; it is in aftercare that Alcoholics Anonymous This is no mean division of labour: patients stand or by the aftercare they receive, and doctors cannot prov it. What doctors can provide in the way of treatm may be seen from Dr. J. P. Henderson's[1] personal acco of alcoholic craving; a more fitting complement to y contributor's story would be hard to find.

Falmouth.
H. Pullar-Strecke

M.R.C.P. EXAMINATION

SIR,—The opinion is indeed widely held that M.R.C.P. is no longer a clinical examination of h standing. This viewpoint would appear to be justi for two reasons: (1) the results of the examination h become notoriously unpredictable, and (2) no candid is required to have done any clinical work. The c regulations with which a candidate must comply some curiously applied rules relating to the prim qualification. The large number of prospective c sulting physicians obviously makes the introductio detailed regulations essential.

The success of even a small proportion of rece qualified doctors who cannot possibly have acquired necessary experience certainly discredits the examinati The numbers who take it "on spec." and find themse on the pass list must be embarrassingly high.

Since the era of the general physician is passing nearly every would-be consultant ultimately speci in one or other of the branches of medicine, we wo whether the London college has considered adopti plan such as that of the Edinburgh membership.

For this examination a candidate must be qualified for years and in addition to "the principles and practic medicine" must offer a special "department of medicine in which a high standard of proficiency is expected." of the two sections of the examination consists of (1) pap (2) a series of short cases in the form of a ward-round and a case for written commentary, with a "clinical-oral on d nostic methods" such as X rays, cardiographs, histolo slides, clinical specimens, &c.; and (3) an oral examina

A test such as this has several advantages. It is and therefore can be thorough. It greatly reduces element of chance. The examination in the proficiency subject is especially attractive to those y enthusiasts who are beginning to pursue their life's interests. One modification, however, which w enhance further the status of the examination woul the extension of the required period after qualifica to three or more years, part or all of which shoul spent in recognised appointments.

M.R.C.P. LON
M.R.C.P.E.

DEATH WHILE BATHING

SIR,—There has often been uncertainty about the real cause of deaths whilst bathing. Those who ha recovered from an attack which apparently would ha caused their death had it occurred while swimming deep water can help to throw light on the subject, Dr. Alexander[2] has done. Zum Busch's[3] account his own experiences suggests that a kind of giant-urticar and faintness following sudden immersion in cold wat may both be explained in the same way, the gia urticaria being due to the release of a histamine-li substance in the skin and subcutaneous tissue, which, too much gets into the general circulation, may cau fainting.[4] A popular summing-up of the histamine p of the subject is given by Langdon-Brown[5]:

> "Every known protein contains . . . histidine. Bre off a single CO_2 molecule from this histidine, and it becom

4. Horton, B. T., Brown, G. E. *Amer. J. med. Sci.* 1920, 178, 1
5. Langdon-Brown, W. *Camb. Univ. med. Soc. Mag.* 1932, 10,

a powerfully toxic substance, histamine. This substance when liberated from the tissue cells can produce all the phenomena of allergy. The chemical basis of allergy is therefore simple . . . but the factors which lead to the liberation of this substance are almost as varied as life itself. Histamine was originally isolated by Barger and Dale from ergot in 1910, and then from the intestines. If it is applied to the human skin, it promptly raises an urticarial wheal; if injected intravenously into animals, it produces a condition like anaphylactic shock. . . . The problem is, how does a substance which is toxic to everybody become liberated only in the tissues of certain people, in answer to stimuli which are quite harmless to everyone else."

um Busch would probably have died had he been in p water at the time of a severe attack. There is a d deal of scattered literature on similar severe tions following sudden immersion in cold water. Goebel[6] relates his personal experience, when he nearly drowned while swimming in water which was cold, on a warm summer day. The accident occurred, ever, soon after the midday meal, and may have n connected with his stomach being full.

ondon, W.1. F. PARKES WEBER.

PPOINTMENTS AND POLITICAL ACTIVITIES

IR,—In the official document "Appointments as mber of a Medical Board Panel under the National urance (Industrial Injuries) Act, 1946" the following tence occurs at para. 5: "In view of the judicial ure of the statutory functions assigned to medical rds under the Act, members are asked to notify the ional medical officer of the Ministry if they play, or end to play, a prominent part in politics." I ther that they will then be called on to resign their pointments.

I submit that the survival of democracy depends on e political activity of its intelligent members.

BELSEN.

MEDICAL RECORDS

SIR,—I should like to support "Medical Secretary's" ea (Aug. 14) for special training for those wishing to come medical stenographers. As medical superintendent of a hospital, I have had to train four shortnd-typists in the last seven years. I personally ctate all the discharge reports and outpatient reports, d the tremendous amount of time wasted in spelling t medical terms, quite apart from the resultant fraying tempers, has to be experienced to be believed.

My present secretary fully agrees with me that there ould be some course of instruction for would-be edical stenographers. When she took up her appointent with me she had had considerable experience in y stenography in the local council offices, and it was lling to her to find her speed reduced to a mere trickle wing to the necessity of getting words spelt, or of oking them up in the medical dictionary.

I have no personal knowledge of the "notorious neanness" of doctors when it comes to paying their cretaries, as I have worked in hospitals all my qualified ife; but I do know that local authorities are slow to ecognise financially the extra application required of nedical stenographers. My secretary receives no more pay than girls with the same number of years' experience n the central office, where the work is purely lay; and et she has to carry in her head details of the spelling of undreds of abstruse medical terms.

I have lately begun to train a new outpatient clerk. nd am feeling to the full the difference between one rained in the use of medical terminology and one who is ot; whereas I am able to dictate my inpatient disharge reports with an average amount of pleasure, I pproach the dictation of my outpatient reports with a eeling of misgiving which very shortly becomes xasperation.

I feel sure that if only they would take the trouble to rite to you, most doctors would endorse the need for uitably qualified stenographers.

MEDICAL SUPERINTENDENT.

Obituary

JOHN KAY JAMIESON

M.B. EDIN., LL.D. LEEDS, M.A., CH.M. DUBL.

Prof. J. K. Jamieson, who successively held the chair of anatomy in the University of Leeds and at Trinity College, Dublin, died on Aug. 20, at the age of 75.

He was born in Shetland, the fourth son of Robert Jamieson of Sandness; and E. B. Jamieson, the Edinburgh anatomist, is one of his brothers. From Madras School, St. Andrews, he went to the University of Edinburgh, where he qualified M.B. in 1894. After holding a demonstratorship in anatomy at Surgeons' Hall in Edinburgh he took up the same post in the University of Leeds under Wardrop Griffith, whom he succeeded in the chair in 1910. During the 1914–18 war, as deputy dean of the faculty of medicine, he proved himself as an administrator and the twenty years of his deanship which followed was a time of notable expansion for the faculty especially in the departments of pathology and physiology. From 1928 to 1936 he was also a member of the General Medical Council, and he acted as examiner for the universities of Edinburgh, Aberdeen, Liverpool, Manchester, Sheffield, Bristol, Dublin, and Belfast.

In 1936, when he had almost reached retiring age, Jamieson was appointed to the chair of anatomy at Trinity College. The intention was that he should retire in 1943 at the age of 70, but conditions that year were unfavourable for the appointment of a successor, so, despite failing strength, shortage of staff, and scarcity of fuel he carried on until last summer. Even then he was not immediately granted a respite, for his successor was unable, through illness, to take up his duties in October and Jamieson continued as acting professor until last December.

Of these years in Dublin J. W. B. writes: "It would not have been easy for anyone to maintain the reputation of a department of anatomy which had had at its head three such men as Alexander Macalister, D. J. Cunningham, and A. F. Dixon, but we asked Jamieson to do something more difficult than that—to break the tradition of the department. Dixon had maintained, unaltered, the Edinburgh tradition which he had inherited from Cunningham, a tradition which was excellent when medical students were given training in little except anatomy in preparation for their clinical work but a tradition which, in the opinion of the younger members of the staff of the school, had outlived its utility. So it fell to Jamieson to reduce the duration of formal teaching in anatomy from eight terms to five and to prove that, while a course of this length might be inadequate for the training of an anatomist, it was adequate for 99% of medical students. No young and inexperienced man and no-one whose reputation had not already been established could have succeeded as well as Jamieson did in this difficult task.

"Jamieson taught form and function and never failed to point out not only what was important in relation to clinical work but also why it was important. His lectures were always interesting and often entertaining, but it was in informal teaching in the dissecting-room that he excelled. There he might be found at any hour of the day, surrounded by a group of eager students each of whom he knew as an individual, dissecting and demonstrating, teaching the dull to use their brains and the clumsy their fingers. He inspired both respect and affection in his students: he never forgot a student whom he had taught and no student ever forgot him.

"The staff of Trinity College changes more slowly than that of most universities and does not readily take to its heart a newcomer. But Jamieson, who had often acted as external examiner, was never regarded as a newcomer. His ability, his honesty of purpose, his sound common sense, his dependability, his wide knowledge of the classics and of English literature, all gained him the respect of his colleagues, but Jamieson gained something rarer than that—their affection. Those he met were first attracted by his little mannerisms, his learning so modestly displayed, his impish sense of humour, his kindness of heart, and, almost before they were aware of it, acquaintance had blossomed into friendship. When he gave—as he so generously did—friendship, he gave it for life. It was kept alive by meetings at long intervals and by his letters, which deserved leisure to read, not because his writing was crabbed or difficult, but because he packed so much into a couple of pages. During the war many widely scattered friends blessed him for the pleasure his letters gave. No doubt others will worthily take the place of Jamieson the great teacher of anatomy, but we cannot hope that anyone will fill the place left vacant in the life of the College by our friend Jimmy."

As a friend of thirty-seven years' standing J. C. B. adds: "Jamieson was a man whose arresting personality, instantly impressive to all on first contact, became a tradition in his own lifetime. When he appointed me his demonstrator, in the second year of his professorship at Leeds, I knew at once that I had acquired a friend as well as a chief; and experience amply proved that beneath a rather forbidding exterior, he imperfectly concealed an inherent kindliness that broke out in unexpected ways and places. Thus to many he had long been known by the revealingly affectionate name of 'Jamie.' With startling exceptions, he had little use for the conventions and conventional procedure. There was an impish quality about all his doings, sometimes disconcerting to his friends and colleagues; and it was a secret delight to him—sometimes not so secret—that he was thought by some to be Machiavellian in his methods. In an old letter, after recounting his reasons for accepting a post offered to him, he goes on: 'The first reason is childish though respectable: the other reasons savour of a life of intrigue. Now, I ask you, am I a crafty and devious person? This will put you up against it to frame an agreeable answer.' But, as a man of affairs, he certainly knew his business, and more often than not got his own way because it was the best way. He had the most penetrating judgment of men and their motives, and his advice, in private as well as in public matters, was always shrewd and solid.

"As a teacher of anatomy Jamieson's reputation was early established and stood high. His practical and characteristically fresh outlook on topography made his lectures and demonstrations occasions to which students looked forward; and they seldom failed to obtain from them ideas and what he himself called 'notions' that stimulated thought and discussion. His main original work—on the surgical anatomy of lymphatic areas in collaboration with the late Mr. J. F. Dobson—has stood the test of time. They employed Gerota's method of injection, and they published, as the fruit of much time-consuming labour, a series of papers, notably on the lymph-drainage of the tongue, stomach, and large intestine, that are now classical. Their principal illustrations of these organs are well known, as inevitably they found their way into the standard textbooks. It is to be regretted that Jamieson—immersed in affairs as he became—did not find time to carry out his intention to incorporate all their results in a volume which certainly would have worthily filled the gap that still exists for a work in English on the lymphatic system.

"Jamieson was an indefatigable and lively correspondent, and doubtless many of his friends possess and have been re-reading collections of his letters—informative, amusing, gossipy, often cryptic and not infrequently pungent in their comments on local and other affairs. In his later years, disabilities, which he had long suffered almost gladly, prevented him enjoying his regular round of golf; but that too became matter for amusing comment and, in spite of the increasing burden, his natural resilience appeared to be almo unabated. By his pupils, his colleagues, and his friends John Kay Jamieson will always be gratefully remembered as a notable and remarkable figure, whom to have known has indeed been a liberal education."

Professor Jamieson married Elisabeth, daughter Dr. R. P. Goodworth. She died in 1936 and they leav a son and a daughter.

JAMES ERNEST HELME ROBERTS

O.B.E., M.D. LOND., F.R.C.S.

Mr. J. E. H. Roberts, consulting surgeon to S Bartholomew's Hospital, and emeritus surgeon to th Brompton Hospital, died at his home at Ottershaw o Aug. 25.

Roberts was educated at King Edwards' Scho Birmingham, and St. Bartholomew's Hospital, where h qualified in 1906, graduating M.B. with honours in surge two years later, and taking the F.R.C.S. in 1909. Aft holding house-appointments at St. Luke's Hospital an at Great Ormond Street, he became demonstrator i surgical pathology and chief assistant surgeon in th outpatients department at Barts and later surgica registrar and chief assistant in the orthopædic departmen In 1919 he was elected assistant surgeon and in 1933 h was appointed to the full staff. He was also surgeon t the East London Hospital for Children.

During the first world war, during which he serve with distinction, holding the rank of major and bei thrice mentioned in despatches, he became interested i thoracic surgery. In 1919 he was appointed to th Brompton Hospital, and from this time his main energie were directed to this branch of surgery, to which he mad considerable contributions, notably in the treatment o acute and chronic empyema. Roberts was the first t use active negative-pressure suction in these condition and his operation for the closure of old chronic empyem cavities has become the most efficient method at ou command. His early reviews of one-stage lobectomy published with the late H. P. Nelson, were a milesto in intrathoracic work.

A good teacher, he gathered a group of enthusiast men around him, encouraging the younger men to furth the work he had already done. One of these young colleagues writes: "Those of us who knew Roberts i his later years respected, admired, and liked him for h pioneering spirit and for the rugged strength of h personality. When he joined the staff of Bromp Hospital surgery of the chest was practically confined t the drainage of empyema, and it was no easy task for t young surgeon to persuade his colleagues to try tho operations which his experience in the 1914–18 w had suggested. No-one will ever know how much w owe to Roberts and how many of the operations whi are now commonplace were the result of his pioneer wor His inquiring scientific mind enabled him to work o his techniques on a sound mechanical basis, and he w never happier than when arguing with the physiologis and applying their principles to his work. No surge ever worked more thoughtfully. He also had uniq powers of observation, and those who went round th wards with him could not fail to be impressed by h clinical judgment; they always came away with som practical point to remember. Above all, Roberts was fighter; his ideas were not always popular but h pursued them with courage and with a dry sense humour which endeared him to his friends. He nev avoided criticism, and was always prepared to produ a closely reasoned argument. All his friends will rememb the backward tilt of his head and the triumphant twink in his eyes as he scored his point."

Roberts's interest in the scientific aspect of surger was shown by the variety of scientific bodies with whic he was associated. As one of its earliest presidents h gave the Society of Thoracic Surgeons considerab impetus, and more recently, from the chair of the Tube culosis Association, he showed how admirably medici and surgery could be blended in one person. To th Medical Society of London, over which he had al presided, he delivered in 1935 the Lettsomian lectures he surgery of pleural and pulmonary infection. A member of the International Association for Surgery, he was also a foreign associate of the Société Belge de Chirurgie, and an honorary fellow of the American Association of Thoracic Surgeons and of the Polish Society of Surgeons of Warsaw. A valued member of he Standing Advisory Committee on Tuberculosis from its nception to the time of his death, his advice on the surgical ontrol of this problem was of the utmost importance.

With all his medical activities, he still found time for ther interests, and he became a recognised authority n dragonflies and alpine plants. Till the beginning of he late war his holidays were spent in the Alps, and at is home he had a superb collection of these plants. P. T., to whom we are indebted for much of this memoir, adds: "Roberts was often brusque, almost to he point of rudeness, but those who knew him well ully appreciated the kindness which underlay his rusqueness. His apparent offhandedness could be ttributed to his absent-mindedness: it was possible o talk to him for a considerable time without his being ware of it, and only persistent effort could break into hese absent-minded periods. Once his attention was ngaged he gave himself wholly to the matter in hand. All those who were privileged to know him will regret he passing of a loyal friend."

Another colleague, paying tribute to Roberts's contribution to chest surgery, continues: "His sanatoriums will sadly miss his regular visits which, though not always starting exactly at the appointed hour, were demonstrations of expert craftsmanship larded with ntervals in which words of real wisdom and experience mingled with cigarette smoke. In debate or discussion his comments could be trenchant, but to the individual—and particularly to his juniors—he was invariably kind and helpful, and behind his reserve he was a most charming and gracious companion."

Mr. Roberts married Coral, daughter of the late Captain J. A. Elmslie, R.N.R., who survives him.

PERCY ROYCROFT LOWE

O.B.E., B.A., M.B. CAMB.

Dr. P. R. Lowe, formerly president of the British Ornithologists' Union and chairman of the European and British section of the International Committee for the Preservation of Birds, died on Aug. 18 at the age of 78. For many years he was in charge of the bird room of the British Museum (Natural History).

From Jesus College, Cambridge, he went to Guy's Hospital, where he qualified in 1897. After holding house-appointments at Leicester and Derby he went to South Africa in 1899 as one of the six civil surgeons chosen by the War Office to serve in the South African War. While medical officer in charge of a hospital train he began his collection of birds, and on his return from South Africa he was able to continue this work while acting as private physician to Sir Frederic Johnson, with whom he visited the West Indies. His collection of island forms of birds made during these voyages is now in the British Museum. During the 1914–18 war Lowe again commanded an ambulance train and for his services he was appointed O.B.E.

In 1918 his appointment as keeper at the British Museum enabled him to devote the rest of his life to ornithology. His work for the preservation of wild fowl was recognised by the award of the Swedish Verner von Heidenstam gold medal in 1939, and his researches in bird anatomy and classification by the Salvin gold medal in 1946. He also represented the Government and the Home Office at various ornithological congresses on the Continent.

A colleague writes: "A man of great charm and of fundamental kindliness, Dr. Lowe would take any amount of trouble to help anyone, and he was always ready to encourage those younger and less knowledgeable than himself. As a chairman his tact, sense of justice, and ability to see another's point of view, won the love and trust of his colleagues of other nations. Though ornithology was Dr. Lowe's chief interest he was a botanist of no mean order and his delight in finding a new plant never waned."

Notes and News

PRIVATE PRACTICE FROM HEALTH CENTRES

In answer to an inquiry concerning a proposed experimental health centre at Stechford, Birmingham, the Minister of Health has informed the local executive council that doctors will not be allowed to treat private patients at centres set up under the National Health Service Act. The *Times* (Aug. 31) reports that the general-purposes committee of the council is seriously concerned at this ruling, and will recommend, at the first annual meeting of the Executive Councils Association, in London on Oct. 7, energetic measures to reverse the Minister's decision. A draft resolution to be submitted to the association expresses the view that if this decision is not reversed, it may be impracticable to operate health centres.

OPHTHALMIC PRESCRIPTIONS

The method of writing an ophthalmic prescription generally accepted in this country and in the U.S.A. is:

Right Eye: Sphere.......... Cylinder..........
Left Eye: Sphere.......... Cylinder..........

A large firm of optical manufacturers points out that some doctors now practising in this country make out prescriptions in the reverse way, writing the cylinder before the sphere, and the left eye before the right. Often these prescriptions are passed on to manufacturers whose staffs are trained in the conventional method of composing them; so a large number of returns is incurred which could be avoided if all doctors adhered to the normal practice.

DEEPER AND DEEPER

The "record" of 480 ft. for deep diving put up in 1945 by Arne Zetterstroem (*Lancet*, 1945, ii. 292) has been beaten by Petty Officer William Bollard, who reached a depth of 535 ft. in Loch Fyne on Aug. 28 (*Times*, Aug. 30). This dive was made in an Admiralty flexible deck diving-suit, and, in view of the fact that Zetterstroem died on the way to the surface, it is not surprising that Bollard, though he reached 535 ft. at 9.29 A.M., was not allowed out of the decompression chamber until 4.45 P.M. The previous "record" held by a diver who survived the ascent was that of Nohl, of Milwaukee, who reached 420 ft. in a diving-suit of his own invention (End, E. *J. Industr. Hyg.* 1938, 20, 513). Petty Officer W. Soper also broke the American record on Aug. 28 by diving to 480 ft. It is but fair to say that Nohl's dive was limited by the depth of water in Lake Michigan. We are not told whether Bollard reached the bottom of the loch or not.

URINE TESTING WITHOUT HEAT

An ingenious modification of Benedict's test for sugar in the urine is now available, in which no external heat is required. The test, known as 'Clinitest,' is carried out by placing five drops of urine plus five drops of water in a test-tube. One clinitest tablet is then added, a few seconds allowed to elapse for the reaction to occur, and the colour then compared with a colour chart. The tablet contains anhydrous copper sulphate, anhydrous sodium hydroxide, citric acid, and sodium bicarbonate. About half of the necessary heat is furnished by the heat of solution of the anhydrous sodium hydroxide and about half by the heat of the neutralisation reaction between sodium hydroxide and citric acid. Clinitest, which has been approved by the medical subcommittee of the Diabetic Association, is distributed by Don S. Momand Ltd., 57, Albany Street, London, N.W.1, from whom further details can be obtained. The complete set, including bakelite case, apparatus, and reagent tablets for 36 tests, costs 12s.

MEDICAL PROTECTION SOCIETY

For this society 1947 was a year of continued success and progress, during which 1501 new members were enrolled. It was also a particularly busy year because of the large number of questions about the new health service. In the annual report the society's solicitor comments on the growth in the number of needles broken during injection. In each instance where a metallurgist's report has been obtained a flaw in the metal has been found; but a word of warning is added on the adverse effect of iodine on steel. The society recently dealt with a case where a needle had broken because of pitting caused by iodine, in which it had been immersed for only a very short time. "It is most important that practitioners should realise that iodine should not be used in connection *with injections and that stainless steel needles should be* kept away from all contact with iodine." The solicitor also remarks on the extraordinary increase, compared with pre-war years, in cases of fractured jaw due to tooth extraction. The council's decision to keep the annual subscription at £1 is a tribute to the health of the society's finances, for the annual cost per member has risen from 15*s.* 4*d.* in 1945 to £1 3*s.* 3*d.* last year. This *increase is attributed to rising costs in general,* and in particular to the award of much heavier damages by the courts.

J.A.M.A.

British readers of the *Journal of the American Medical Association* have been glad to see in the issue for Aug. 7, the latest to reach us, that the journal's printing troubles have ended.

University of Leeds

Prof. J. W. McLeod, F.R.S., is to succeed Prof. Matthew Stewart as dean of the medical faculty. Professor Stewart is retiring owing to pressure of other work. He has been academic subdean since 1923, and dean since 1941.

Prof. W. E. Le Gros Clark, F.R.S., is to give the *inaugural* lecture of the faculty of medicine at the University Union on Tuesday, Oct. 12, at 3 P.M. He has chosen as his subject Intellectual Adventure.

University of Aberdeen

Mr. W. O. Kermack, D.SC., F.R.S., has been appointed to the new MacLeod-Smith chair of biological chemistry. Dr. Kermack has been director of the chemical department of the research laboratory of the Royal College of Physicians of Edinburgh since 1921.

Royal College of Physicians of London

Dr. F. M. R. Walshe, F.R.S., will deliver the Harveian oration at the college, Pall Mall East, S.W.1, on St. Luke's day, Monday, Oct. 18. He is to speak on the Structure of Medicine and its Place among the Sciences.

Society of Apothecaries of London

Ten postgraduate lectures on modern therapeutics will be delivered in the hall of the society, Black Friars Lane, E.C.4, from Oct. 18 to Nov. 5. Further particulars will be found in our advertisement columns.

Institute of Laryngology and Otology

On Tuesday, Sept. 7, at 9.30 A.M., at the institute, 330, Gray's Inn Road, London, W.C.1, Mr. Myles L. Formby will give a lecture on Non-operative Treatment of Maxillary Sinusitis.

Tuberculosis Course

A refresher course for doctors on the treatment of non-pulmonary tuberculosis including lupus will be held at Lord Mayor Treloar Cripples' Hospital, Alton, Hants, from Oct. 5 to 7. Further particulars may be had from Dr. Harley Williams, N.A.P.T., Tavistock House North, London, W.C.1.

Congress of Obstetrics and Gynæcology

The *twelfth British Congress of Obstetrics and Gynæcology* will be held from July 6 to 8, 1949, in the Friends Meeting House, Euston Road, London, N.W.1, under the presidency of Sir Eardley Holland. Subjects already chosen for discussion include: Modern Cæsarean Section (opener, Mr. McIntosh Marshall); Essential Hypertension in Pregnancy (Prof. George Pickering and Prof. F. J. Browne); Diagnosis and Prognosis of Carcinoma of the Uterus (Dr. J. E. Ayre and Dr. F. G. Spear); and Maternal Mortality. The hon. secretaries would like to have the names of those who hope to attend not later than March 31.

Whitley Councils

Some of the Whitley council machinery described in our issue of May 29 (p. 845) is now in being. The general council, *which will deal* with questions affecting more than one group of workers, has not yet been established, but of the functional councils covering the different classes of people engaged in the health service the following have been or are being set up: optical, pharmaceutical, nurses and midwives, professional and technical grades (two councils, A and B). The membership of the medical and dental councils is still being discussed with the organisations concerned.

Edinburgh Post-Graduate Board for Medicine

On Friday, Sept. 10, at 3.30 P.M., in the anatomy theatre of the university, Dr. W. Ritchie Russell will sp on Localisation of Cerebral Function.

North West Metropolitan Regional T Society

At a meeting of this society to be held on Oct. 6, at 4.30 at Colindale Hospital, N.W.9, Dr. H. M. C. Macaulay will o a discussion on the development of the tuberculosis serv in the region.

Supplies of Diphtheria Antitoxin

Stocks of diphtheria antitoxin are now held by a pharmacists and by infectious-disease hospitals. In cent where these hospitals are not readily accessible, the of Health has arranged for a small supply to be kept at convenient general hospital.

Medical Films

The three morning film shows organised by the S Film Association in connexion with the international film congress will be held on Oct. 8 and 11 (cf. p. 360 of issue of Aug. 28) at the Royal Society of Medicine, and Oct. 9 at 1, Lambeth High Street, S.E. Applications admission should be addressed to the organiser at 34, Square, W.1.

Corrigendum.—The English publishers of Sulfonami and Allied Compounds, by Dr. E. H. Northey, reviewed *our issue of Aug. 7 (p. 220), are Messrs. Chapman* and and the price is 75*s.*

Appointments

Hayward, G. W., M.D. Lond., F.R.C.P.: physician for disease the heart, Southend-on-Sea General Hospital.

Matheson, J. G., M.B. Aberd., D.A.: specialist anæsthetist, Ro Edinburgh Hospital for Sick Children.

Morgan, N. H., O.B.E., F.R.C.S.: asst. orthopædic surgeon, De group of hospitals.

Price, D. E., M.B. Lond.: pathologist in the Home Office.

Births, Marriages, and Deaths

BIRTHS

Bevan.—On Aug. 21, at Kyperounda, Cyprus, the wife of Dr. C Bevan—a daughter.

Birt.—On Aug. 25, at Godalming, the wife of Mr. St. John F.R.C.S.—a son.

Borland.—On Aug. 22, at Sunbury-on-Thames, the wife of A. K. Borland—a daughter.

Carter.—On Aug. 24, in London, the wife of Dr. F. S Ca —a son.

Cookburn.—On Aug. 21, at Selsdon Vale, the wife of Dr. H Cookburn—a daughter.

Denham.—On Aug. 22, the wife of Captain Robin Denham, R.A —a son.

Hallett.—On Aug. 27, at Lymington, the wife of Mr. Geoff Hallett, F.R.C.S.—a daughter.

Kennedy.—On Aug. 20, at Penarth, South Wales, the wife Dr. Michael Kennedy—a son.

Loughborough.—On Aug. 20, at Gosport, the wife of Dr. Jo Loughborough—a son.

Murphie.—On Aug. 28, *in London, the wife of* Mr. C. I. Murph F.R.C.S.—a daughter.

Solomon.—On Aug. 26, at Orendon, Bucks, the wife of Dr. R. Solomon—a son.

Wadia.—On Aug. 23, in London, the wife of Dr. Richard Wa —a daughter.

Waugh.—On Aug. 24, in Edinburgh, the wife of Dr. I. G. Wa —a son.

MARRIAGES

Dickinson—Carnegie.—On Aug. 24, at Baswich, Staffs, Jame Dickinson, M.B., to Ailsa Margaret Carnegie.

Ross—Wilson.—On Aug. 26, at Arbroath, James McLean Ro M.B.E., F.R.C.S.E., to Kathleen Margaret Wilson.

DEATHS

Brogden.—On Aug. 27, at Maybury, Woking, Surrey, Geo Alexander Brogden, M.A. Camb., M.D. Edin., aged 78.

Burton.—On Aug. 23, at Frodsham, Cheshire, William Edw Burton, M.R.C.S., D.P.H., J.P., aged 82.

Carver.—On Aug. 25, 1948, at Sutton Courtenay, John Robert Carver, M.D. Camb., D.P.H.

Lowbury.—On Aug. 24, in London, Benjamin William Lowbu M.D. Berlin.

Roberts.—On Aug. 25, at Ottershaw, James Ernest Helme Robe O.B.E., M.B. Lond., F.R.C.S.

Young.—On Aug. 28, at Tavistock, Augustus Henry Owen You L.R.C.P.I., lieut.-colonel, R.A.M.C.

MODERN PHONOCARDIOGRAPHY

G. E. Donovan
M.D., M.Sc. N.U.I., D.P.H.
CAL OFFICER OF HEALTH, LLWCHWR AND GOWER; MEDICAL
PERINTENDENT, GARNGOCH ISOLATION HOSPITAL, GLAM

ODERN American practice is to record the heart ıds (1) linearly, the vibrations due to the underlying iac action being portrayed as they exist on the surface ıe chest; (2) stethoscopically, an oscillogram of the t-sound vibrations being registered as they are nitted to the ears by the orthodox acoustic stetho- ; and (3) logarithmically, to agree roughly with a etent auscultator's auditory perception of the heart s as heard through a stethoscope if the personal s are omitted.

"logarithmic" or, as it is sometimes called, the ıan audiographic" phonocardiogram is somewhat a mer. It is a phonocardiographic term and is used by me limited sense. It means that added frequency distortion h a character has been introduced into a stethoscopic cardiograph that the resultant phonocardiogram bles approximately what the auscultator using the dox acoustic stethoscope recognises as normal. This is customarily used in phonocardiography and has by probably received sufficient sanction by usage to be ted.

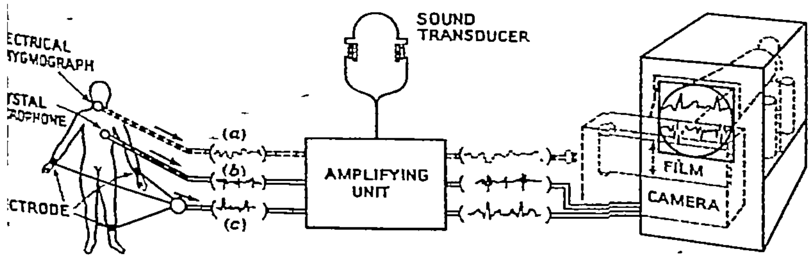
ch of these standard records can be correlated with nderlying cardiac action. There is no reason why intermediate positions should not be used, but the r, stethoscopic, and logarithmic phonocardiograms ld be the standard ones.

THE PHONOELECTROCARDIOSCOPE

ıe details of my method have already been described ıovan 1943a, b, c, d, 1944, 1945). The apparatus ists essentially of a double-channel electronic-valve lifying unit fitted with frequency controls, intensity rol, and tone-compensated volume control, a double- n cathode-ray oscilloscope fitted with a long- istence fluorescent screen, recording camera, head- ıes, and accessories such as a special crystal ophone, electrocardiographic leads, and photo- tric plethysmograph. Fig. 1 is a simplified schematic ram of the apparatus.

he apparatus permits the direct, instantaneous, ıltaneous, and constant viewing of a pair of cardiac nomena such as the phonocardiogram and electro- liogram, phonocardiogram and sphygmogram, &c., the fluorescent screen of the cathode-ray oscilloscope he patient's bedside without the necessity of photo- phic registration and consequent loss of time in eloping film. The amplified heart sounds are heard ough moving-coil headphones by one or many auscul- ors while the traces are being directly observed on the een The auditory and visual impressions can be ıultaneously compared.

Fig. 2 shows the instrument in use, with a simultaneous arithmic phonocardiogram of one cardiac area and that of another on the fluorescent screen of the double-beam cathode-ray oscilloscope as they appear for direct visual observation. The photograph had to be taken in dim light, because the exposure had to be a compromise between those required for the images on the fluorescent screen, the apparatus, and the patient.



(a) JUGULAR PULSE (b) PHONOCARDIOGRAM
(c) ELECTROCARDIOGRAM

Fig. 1—Simplified schematic diagram of phonoelectrocardioscope.

Permanent graphic records can be made by focusing the camera on the fluorescent screen of the double-beam cathode-ray oscilloscope and photographing one traverse of the pair of cathode-ray spots as they appear for visual observation—opening the shutter at the beginning and closing it at the end of the traverse of the spots. Where permanent records are desired as a routine, the traces are recorded on moving film and the spots are stationary in the horizontal axis but oscillate in the vertical axis.

The apparatus can be calibrated by injecting a small known voltage into the input of the amplifier. A transparent ruled graticule in front of the fluorescent screen assists in quantitative measurement.

Special Microphone

The microphone consists essentially of a cartridge or diaphragm crystal unit mounted in a special airtight case. The diaphragm acts as an acoustic transformer which increases the coupling between air and crystal and so increases the sensitivity. The air chamber in front of the diaphragm has an air-pressure equalising valve which connects the air of the space between the diaphragm and the patient's skin to the external air, and whose function is to protect the crystal from injury while the microphone is being applied to the chest wall. The valve is opened to allow the escape of the sudden high pressure while the microphone is being applied, but closed during the actual recording of the phonocardiogram. The chest-piece of the microphone is electrically insulated so as not to affect the registration of the electrocardiogram.

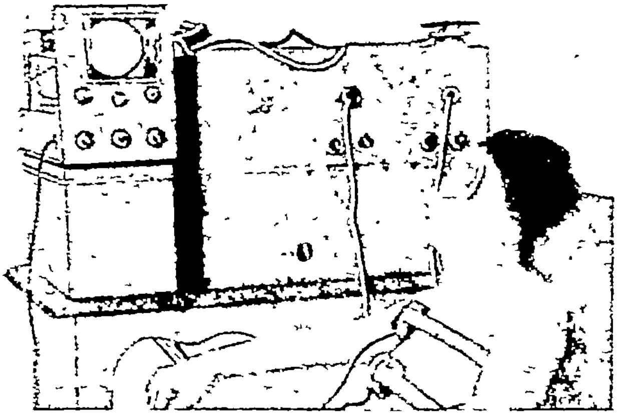


Fig. 2—Author's apparatus in use. Simultaneous logarithmic phonocardiogram of one area and logarithmic phonocardiogram of another area appear for direct visual observation on fluorescent screen.

The natural period of the piezo-electric crystal incorporated in the microphone is about 10,000 cycles per sec.; but, owing to a diaphragm being coupled to the crystal, the natural period of the combination is lowered to a few thousand cycles per sec., which is well above the upper frequency limit of 1000 cycles per sec. for phonocardiography.

The microphone is sensitive and light, has a low parasitic background noise, and, unlike the carbon

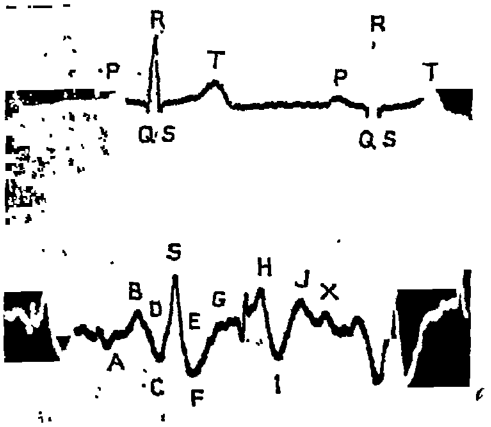

Fig. 3—Normal electrocardiogram lead 2 and jugular phlebogram (recorded by all-electric method) as they appear for direct visual observation on fluorescent screen. *This type of jugular phlebogram,* unlike electrocardiogram, demonstrates *nearly* every phase and event *in* cardiac cycle. Electrocardiogram lead 2 shows P, auricular wave ; QRS, *ventricular initial* complex ; and T, ventricular terminal wave. Jugular phlebogram shows different phases of systole and diastole : ABC, approximate duration of auricular systole (A-C interval) ; CD, *isometric contraction* ; *D,* closure of A-V valves ; S, interval of systole filled by large positive wave due to impact *from* adjacent artery ; *SE,* sharp decline at onset of systolic ejection and descent of ventricular base ; G, second heart sound ; GH, phase of isometric relaxation ; H, opening of A-V valves ; *HI, rapid ventricular* inflow ; I-X, diastasis (period of slow inflow) ; X, end-point of diastole.

microphone, is relatively unaffected by handling, since it has no loose granules. It has a suitable impedance *to* work without a transformer and does not require polarising potentials. The only type of shielding required is electrostatic.

The frequency response of the microphone is excellent for logarithmic and stethoscopic phonocardiography. The microphone's time constant is artificially increased by shunting with a 1 mF condenser in registering the linear phonocardiogram ; this enables the microphone to register such slow pulses as the jugular pulse.

Amplifying Channels

There are two separate channels of amplifications which are resistance-capacity coupled. The maximal amplification of each channel is 500,000 times, and the frequency response is flat within $\pm 7^{1}/_{2}\%$ between 0·15 and 5000 cycles per sec. Electric filters are incorporated which narrow down the frequency bands of observation to reduce the amount of extraneous and interfering variations outside the frequency range of interest. I prefer electric filters, unlike some American workers who use an acoustic high-pass filter incorporated in the case of

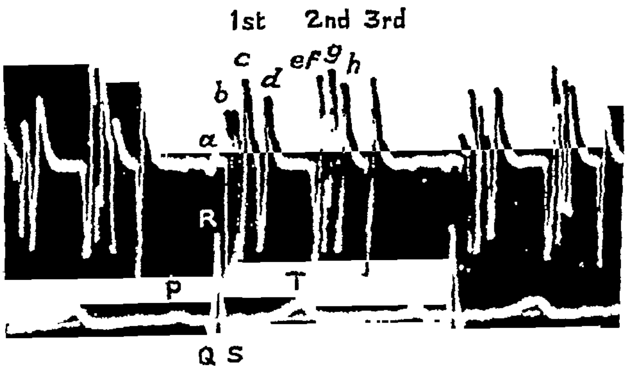

Fig. 4—Innocent triple rhythm in normal person. Record shows simultaneous stethoscopic apical phonocardiogram and lead I of electrocardiogram of a boy, aged 10 years, recorded on moving film. the microphone. They get various degrees of action by using four chest-pieces with such
The electric filters have the advantage that the
phone is left in situ, and it takes only a few
get 25 different combinations by rotating two

Double-beam Cathode-ray Oscilloscope

The cathode-ray tube is the most faithful medium available to the physiologist. Unlike *instruments* used for this purpose (e.g., string meter and mirror galvanometer) the moving the cathode-ray oscillograph—a stream of possesses practically no mass and is consequentl tically without inertia. It can therefore respond to the most rapid variations of potential withou damping or overshooting. It is immune from by deflectional overload. It is robust and easy to pulate. The variations can be studied in relation by using a linear time base on the horizontal plates of the cathode-ray tube.

The fact that the double-beam cathode-ray two spots (which produce a long afterglow or rescence lasting several seconds) capable of in deflection in the vertical or Y-direction while deflected simultaneously in the horizontal or from the left to the right borders of the flu screen by a common time base permits direct simultaneous, and continuous observation phenomena such as a phonocardiogram and cardiogram, or a phonocardiogram and sph The speed of the time base can be varied to sho

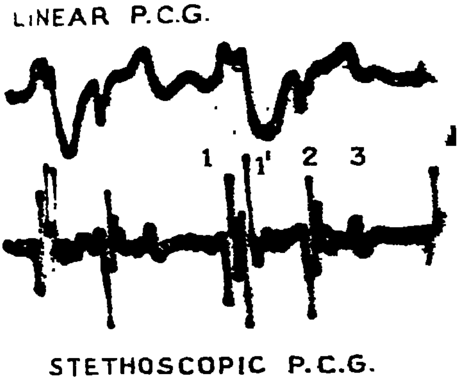
one to several heart cycles on the fluorescent scre varying the amplification of the amplifying and the speed of the time base, an expanded heart oscillogram and electrocardiogram can be seen screen.

INTERPRETATIVE TRACES

It is desirable for the interpretation of the cardiogram to have it accompanied by a simul electrocardiogram or phlebogram. The electroc is the more popular interpretative trace i country, but the phlebogram has many adv its value is being increasingly recognised, espec America.

Fishberg (1940) expresses the generally held " unfortunately to obtain a good tracing of the pulse is often a task of considerable difficulty, a interpretation of the records is frequently ob Bramwell and King (1942) say that the method is of historical interest, since most information gi the phlebograph can now be obtained in a much form with the electrocardiograph.

It must be pointed out that in many ways the cardiogram as a reference trace is not ideal, sin electrical manifestations of cardiac activity a necessarily synchronous with the mechanical event



-Simultaneous linear phonocardiogram and stethoscopic phono- iogram taken over apical area as they appear for direct visual rvation on fluorescent screen, showing splitting of first heart id. For explanation see text.

ar pulse tracing with the latest technique gives thing the electrocardiogram cannot give—i.e., ianical evidence of the action of the heart chambers. a clinical method which produces a graphic record arly every phase and event during the cardiac cycle. jugular pulse trace improves the possibility of ysing the phonocardiogram.

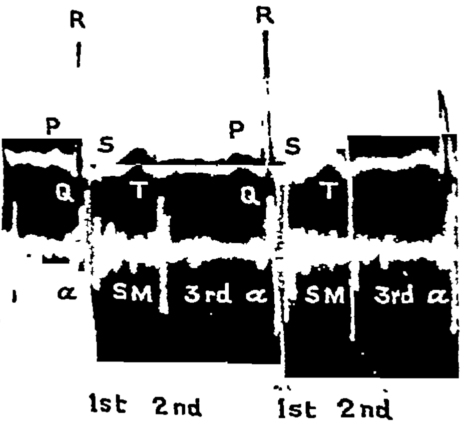
his electrical method has the advantages of compara- simplicity, great accuracy, elimination of rubber ng, possibility of magnification as individually essary, and possibility of synchronisation with other es such as electrocardiograms, phonocardiograms, recorded with more or less identical electrical hods.

use the electrocardiogram as the routine interpreta- trace for the phonocardiogram, but in difficult cases refer the jugular pulse tracing recorded by an electric method.



. 7—Record of simultaneous electrocardiogram lead 2 and apical garithmic phonocardiogram in mitral endocarditis in a woman, ged 20, as they appear for direct visual observation. Auricular com- lex (α) occurs between P and Q waves of electrocardiogram ; central α) complex is separated from first heart sound by an interval and is form of presystolic gallop. First sound is accentuated and is followed y systolic murmur (SM). Second and third heart sounds are also een. Diagnosis is mitral stenosis.

HEART-SOUND RECORDS

The following records were registered with the phono-electrocardioscope.

Case 1.—A stethoscopic apical phonocardiogram and lead 1 of electrocardiogram in a boy, aged 10 years, taken on moving film are shown in fig. 4. The first, second, and third heart sounds are clearly recorded.

The first heart sound has four components: *a*, due to auricular systole; *b*, produced at the beginning of the isometric contraction phase which finishes before the beginning of the ejection phase of ventricular systole; *c*, coincident with the onset of the ejection phase; and *d*, associated with the maximal ejection phase. The auscultator rarely hears the first and fourth components of the first heart sound: the sound he hears comprises the second and third components.

The second heart sound has four components: *e*, coincident with the beginning of the diastolic fall in pressure with relaxation of the ventricle; *f*, coincident with closure of the semilunar valve (end of ventricular systole); *g*, caused by vibrations in the arterial wall and in the aortic column of blood; and *h*, presumably caused by the opening of the mitral and tricuspid valves. The auscultator hears the second component of the second heart sound, but the first, third, and fourth components are attenuated or sometimes obliterated.

The third heart sound is registered well in the stethoscopic phonocardiogram, and its duration range is longer than by the logarithmic method. This sound is generally of low frequency and weak intensity. It is generally very difficult to hear by auscultation. The third heart sound is probably caused by vibrations of the ventricular walls due to their sudden distension by the onrush of blood from the auricles into the ventricles in the period of rapid ventricular filling.

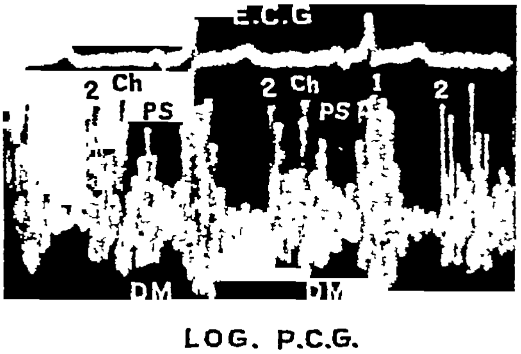


Fig. 8—Electrocardiogram lead 2 and apical logarithmic phonocardiogram in advanced mitral stenosis. Traces were photographed as they appeared for direct visual observation. 1 and 2, first and second heart sounds ; Ch, opening snap of mitral valve ; DM, diastolic murmur.

A logarithmic phonocardiogram of the same patient taken over the same area and accompanied by lead 1 of the electrocardiogram is shown in fig. 5. This type of phonocardiogram tends to agree with the auscultatory impression of the auscultator. The logarithmic phonocardiogram tends to register the second and third components of the first heart sound—i.e., *b* and *c*—but obliterates the first and fourth components, since these are of low frequency. This means that an auscultator can very rarely hear the first and fourth components of the first heart sound. The second and third heart sounds are also affected in this type of recording.

Case 2.—A linear phonocardiogram and stethoscopic phonocardiogram taken over the apical area in a man, aged 20, are shown in fig. 6. The traces were photographed on still film as they appeared for direct visual observation. The linear phonocardiogram can register the first and fourth components of the first heart sound but not so well the second and third components. Third heart sound registers well in this type of record. The stethoscopic phonocardiogram shows splitting of the first heart sound, owing to an exaggerated separation of the two major components of the first sound, the isometric phase and the ejection phase components: this may often occur at the end of expiration. This splitting of the first sound may be, and is in this particular case, a purely physiological event.

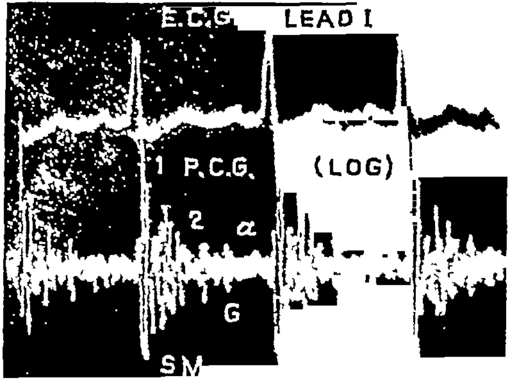

Fig. 9—Electrocardiogram lead I and apical logarithmic phonocardiogram in hypertensive heart disease: 1 and 2, first and second heart sounds; SM, systolic murmur; G, protodiastolic gallop; α, auricular complex. Traces were photographed as they appeared for direct visual observation.

Case 3.—An electrocardiogram lead 2 and a simultaneous apical logarithmic phonocardiogram in mitral endocarditis in a woman, aged 20, are shown in fig. 7. The traces were photographed on still film as they appeared for direct visual observation. The record shows an accentuated first heart sound, a form of presystolic gallop, systolic murmur, and second and third heart sounds.

Case 4.—A record of an advanced case of mitral stenosis in a woman, aged 30, is shown in fig. 8. It shows lead 2 of the electrocardiogram and an apical logarithmic phonocardiogram. The phonocardiogram shows the first and second heart sounds, the opening snap of the mitral valve, and a mid-diastolic murmur. The traces were photographed on still film as they appeared for direct visual observation.

Case 5.—Fig. 9 shows simultaneous electrocardiogram lead 1 and an apical logarithmic phonocardiogram in hypertensive heart disease, photographed as they appeared for direct visual observation. The blood-pressure was 230/140 mm. Hg. The phonocardiogram shows an accentuated first heart sound, a well-marked systolic murmur, and protodiastolic gallop rhythm.

Pulse Velocity.—By recording a simultaneous phonocardiogram or electrocardiogram with the finger-tip peripheral pulse one can time the interval between the beginning of the ejection phase of ventricular activity and the appearance of the pulse in the finger-tip. Fig. 10 is a record of an apical linear phonocardiogram and a peripheral pulse taken through the finger-tip in a man aged 40. The peripheral pulse has been registered by passing a beam of light through the tip of the index finger. The emergent beam strikes a photoelectric cell which changes any variations in the intensity of light into a corresponding variation in an electric circuit. The changes in light intensity vary with the changing blood-volume within the part. The electrical variations due to the varying translucency of the finger-tip are amplified by the second channel of the amplifying unit and are recorded on the fluorescent screen. The rate of propagation of the pulse is an index of the average elasticity of the arterial stem.

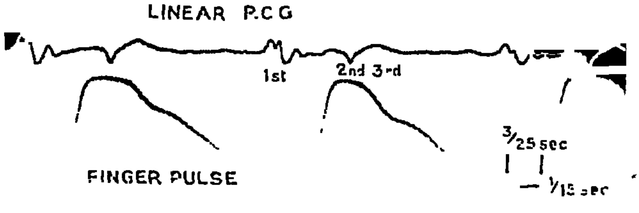

Fig. 10—Simultaneous linear apical phonocardiogram and peripheral finger-tip pulse recorded by author's photoelectric plethysmograph. Traces were photographed on moving film.

CONCLUSIONS

Much of the discussion by clinicians on phor graphy is unsound because of their failure to the important difference between heart-sound r registered by apparatus of widely different charact Various types of phonocardiograms, such as the arithmic, stethoscope, and linear, have not infre been erroneously compared as if they were the detail. It is possible that many of the inaudible which can be recorded may eventually prove to almost as much clinical significance as have the sounds and murmurs.

The time has come when a committee should be up for the standardisation of phonocardiographs. standardisation should not be too rigid, since it retard progress.

I wish to thank Mr. H. Marriott, B.ENG., B. A.M.I.E.E., lecturer in electrical engineering at College, London, for his help.

STUDIES of the pathogenesis of pernicious an have been hindered by our inability to reproduce disease experimentally in an animal, and by the abs of a test for the therapeutic potency of liver extr other than their clinical trial. Many tests have b suggested for the assay of liver extracts; King (1 has reviewed these and points out that none has b proved of value. Castle's (1929) observations sugges that pernicious anæmia might be produced experiment by resection of the stomach, but in practice exp mental resections of the stomach, alone or accompan by resection of part of the small intestine, have failed produce the disease in the several species which have b used (Petri and Jensenius 1941, Jensenius 1945). some recent dietary experiments (Cartwright et 1946, Welch et al. 1947) a macrocytic anæmia been produced by adding a folic-acid antagonist t purified diet. It is uncertain what relation this condit bears to the natural disease.

Another line of approach is suggested by the occasio association, in man, of anæmia closely resembl pernicious anæmia with gross intestinal disease. T has been known since Faber's (1897) report, and Ba and Hummel (1939) collected 51 cases of macroc anæmia in association with intestinal stricture anastomosis. Other cases have been reviewed Jensenius (1945). In anæmia of this type the bl picture is often indistinguishable from that of pernici anæmia, and, where it has been examined, the mar has usually been megaloblastic. The anæmia dif from pernicious anæmia in that achlorhydria and leu nia are variable features, and the incidence of neuro-ical disease is lower. Treatment with liver extracts usually effective, as is surgical correction of the intes-al abnormality. In some of these cases steatorrhœa s been present, and the anæmia has been likened to that of sprue, but study of the case-records suggests that, though steatorrhœa is usual where there is a gastro-colic or high jejunocolic fistula, it is uncommon in other examples of this syndrome. A case under our own observation has shown that steatorrhœa is not an essential feature; in this patient megaloblastic anæmia lowed an operation at which adjacent loops of ileum re anastomosed to by-pass a subacute obstruction m regional ileitis, but the output of fæcal fat, during a ree-day balance experiment, was within the normal nge.

. 1—Operations A and B, showing direction of peristalsis in loops.

Some early experiments suggested that it was possible produce a similar condition in animals. Seyderhelm al. (1924), by forming intestinal strictures in dogs, oduced an anæmia with a blood picture resembling at of pernicious anæmia, and Tönnis and Brusis (1931) tained similar results in dogs by forming blind intestinal ops.

This paper is an account of some experiments of this pe, using rats as the test animal. We found that acrocytic anæmia may follow the formation of either stricture or a blind intestinal loop; but as no reliable eans could be found for producing a non-fatal stricture, op formation was made the standard operation.

METHODS

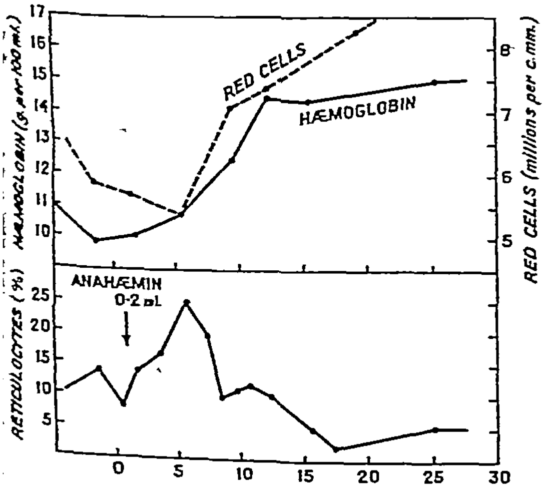
The rats used in these experiments were albinos of istar strain and of either sex. The operations were ne on rats aged 4–6 months; in rats of this age the ood-count has reached the normal adult level. The ts were maintained on a diet of casein, corn starch, and d-liver and arachis oils, with mineral and vitamin pplements; this diet permitted normal growth and production in intact animals, and control animals kept on it for a year did not develop anæmia. The composition of this diet, which was fed in excess, was as follows:

Corn starch	68%
Casein (unextracted)	25%
Cod-liver oil	2%
Arachis oil	2%
Salt mixture [1]	3%

Vitamin supplements:

Thiamine	100 μg.	daily
Riboflavine	200 ,,	,,
Pyridoxine	100 ,,	,,
Calcium pantothenate	200 ,,	,,
Vitamin K..	40 ,,	,,
Nicotinic acid	1 mg.	,,
Choline hydrochloride	10 ,,	,,

In addition vitaminised oil containing 2000 units of vitamin A and 200 units of vitamin D was given twice weekly, and 3 mg. of α-tocopherol was given once weekly.



ig. 3—Response of rat with ma……cytic anæmia given anahæmin ……n A).

It is probable (Jensenius 1945) that at least a third of the small intestine can be excised without serious effect on nutrition, and for the initial experiments the loop was made this length—about 12 in. Two types of operation were used: (1) in operation A the direction of peristalsis was such as to tend to empty the loop (fig. 1, A); and (2) in operation B peristalsis tended to fill the loop (fig. 1, B). In a later modification of operation B the length of the loop was reduced to 3 in.

RESULTS

Macrocytic anæmia followed each operation in a proportion of the animals submitted to it, and its characteristics were the same for each type of operation. It was found, however, that anæmia developed after operation A only when there was some stenosis at the site of anastomosis, leading to dilatation of part of the loop. For this reason operation B was adopted, and this gave a much higher proportion of anæmic animals, though the immediate mortality after this operation was higher owing to its technical difficulty. After this operation the loop always becomes dilated.

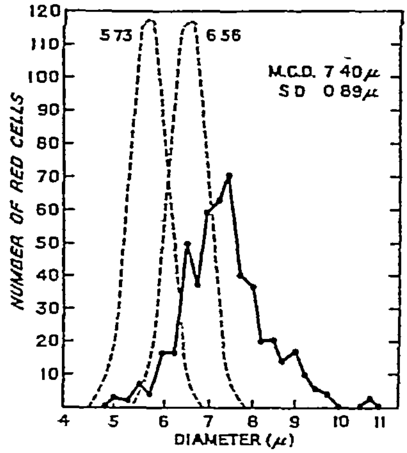


Fig. 2—Price-Jones curve from anæmic rat. Curve reveals macrocytosis and anisocytosis. Interrupted lines show limits of normal curves for rat blood, using Price-Jones convention of ±3 standard deviations.

Of the rats prepared by operation A 118 survived its immediate effects, and 21 (18%) of these developed macrocytic anæmia, at times varying from six weeks to a year after operation. With operation B, using a long loop, the mortality by the end of three weeks approached 75%; and, though by that time nearly all the surviving rats had a macrocytic anæmia, the disturbances produced by so large a loop were excessive, and the rats could not be saved with liver extract. When this operation was *modified by shortening the loop to 3 in.*, results were more satisfactory: of 24 rats prepared in this way 17 survived, and 13 of these have developed macrocytic anæmia at an average interval of 8 weeks after operation.

DESCRIPTION OF THE ANÆMIA

The normal hæmoglobin level in our rats is about 14 g. per 100 ml., and anæmia has not been diagnosed unless the hæmoglobin has fallen below 10 g. per 100 ml. In practice it is found that the rats either remain well or become progressively and severely anæmic. The red cells, which are normally a little fewer than 9,000,000 per c.mm., often fall at the same rate as the hæmoglobin, with the result that the colour-index does not change, but in some rats there has been hyperchromia. A count as low as 3·3 g. of hæmoglobin per 100 ml. and 2,150,000 red cells per c.mm. has been found, but usually the rat dies before the anæmia becomes so severe.

---

[1] As recommended by Hubbell et al. (1937).

The presence of macrocytosis has been shown by increases in the mean cell diameter and by an extension of the Price-Jones curve beyond the upper limits of normal, and confirmed in several cases by an increase in the mean cell volume. The normal mean cell diameter is 6·14μ, and in anæmic rats mean diameters as large as 7·40μ have been observed; the average increase is about 0·6μ. The normal mean cell volume is $49\mu_3$; readings of $70\mu_3$ or more were sometimes seen, but estimates of the mean cell volume are subject to considerable error, and increases in the mean cell diameter were not always accompanied by an increase in the mean cell volume. *Anisocytosis was a striking feature of the* anæmia, but poikilocytosis was never more than slight.

The first 6 rats were prepared by operation A, and the last 6 by operation B.

The anæmic animals have an irregular reticulocytosis manifested in the stained films by increased polychromasia. Nucleated red cells were usually present in peripheral blood films. Leucocytes were present in normal numbers and did not show appreciable qualitative change. Some of these points are illustrated in figs. 5 and 6. In fig. 7 a blood film is shown from a rat with a hypochromic normocytic anæmia; this type of anæmia was *occasionally seen after operation A only, and the* appearance of the film is in striking contrast to that seen in macrocytic anæmia. These photomicrographs are all at the same magnification. Fig. 2 is a Price-Jones curve from a rat with macrocytic anæmia.

Once anæmia has appeared it usually progresses fairly rapidly if untreated, and the limit of survival appears to be about a month. A few anæmic animals prepared by the earlier technique had spontaneous remissions of their anæmia, but this has never happened after operation B. Animals with anæmia tend to lose weight and regain it with a therapeutic remission. They do not show any external evidence of deficiency disease. The

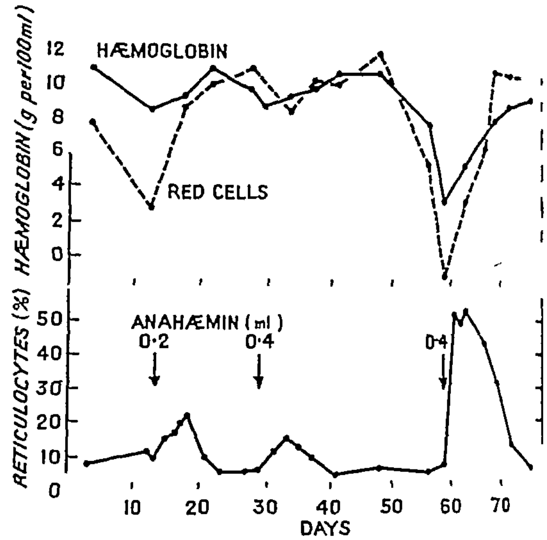

Fig. 4—Responses of rat with macrocytic anæmia given injections of anahæmin (operation A).

accompanying table gives representative examples, various levels, of the blood findings in animals anæmia.

CHANGES IN THE BONE-MARROW

Bone-marrow smears were made from normal anæmic rats by a method which did not involve of the animal (Cameron and Watson 1948). from rats with macrocytic anæmia showed increased cellularity, and the most striking ch distribution was an increase in the proportion of red-cell precursors. In smears from normal rats predominant cells of the erythroblast series are polychromatic normoblasts with dense or nuclei; this distribution was unaltered in rats to repeated hæmorrhage, but in rats with anæmia there were increased numbers of pro- blasts and basophil erythroblasts. The degree of change varied considerably in different rats. No were seen which corresponded exactly to the blasts seen in human pernicious *anæmia*, but there some cells of the erythrocyte series which *abnormal in that the nucleus did not have the* character seen in cells from normal marrow, *occasional cells had a closer resemblance to the* blast. Marrow from anæmic rats showed increa numbers of plasma cells, but there were no apprecia

anges in the myeloid series. Figs. 8 and 9 are photo-
aphs of marrow from a normal rat and from an anæmic
t with a well-marked shift to the left of the red-cell
ries.

EFFECT OF LIVER THERAPY

If the rat is to be used as a test object for the anti-
rnicious-anæmia principle or for similar purposes, it is
portant that the amount of the hæmoglobin should
t be allowed to fall too low. The rat is a small animal
th a brisk metabolism and does not tolerate anæmia
ll. If the hæmoglobin falls much below 7 g. per 100 ml.
e rat becomes torpid and sleepy, its nutrition and resis-
nce to infection are impaired, and the state of ill-
alth may become irreversible. For this reason tests
e probably made best at a level of 7–9 g. of hæmoglobin
r 100 ml.

A commercial preparation, 'Anahæmin,' was used to
udy the effect of liver extract on the macrocytic
æmia; the extracts which were used had been tested
inically in man and found to be active. Anahæmin
as given by injection in doses of 0·1–0·4 ml. to 17 rats
epared by operation A; 10 of these showed a response
the liver extract. Of the 7 rats which did not respond
4 had extensive septic infections and 2 had a fatal degree of intestinal obstruction. The observed responses to liver extract varied considerably in degree; the responses of 2 animals are shown in figs. 3 and 4. These results suggested that the anæmia responded to liver when it was not complicated by infection. More clear-cut results were obtained with rats prepared by operation B, with a 3-in. loop; there were no complicating infections in this group. From a group of 10 anæmic animals 5, chosen at random, were left untreated; these rats all died with a progressive anæmia, none surviving more than a month after anæmia was first noted. Of the remaining 5 rats 4 were given one or two injections of 0·4 ml. of anahæmin; these all showed a response to the liver and have remained alive and under observation for as long as eight weeks. The response to liver extract was again rather variable, 2 rats regaining completely normal blood-counts, while the other 2 had improved but still subnormal counts. The remaining rat of this group was injected with 15 mg. of synthetic folic acid; it too has shown a satisfactory response, the hæmoglobin and red-cell count rising nearly to normal in fourteen days. More observations are necessary to determine the optimum dose of liver extract. These preliminary observations suggest that, when an adequate dose of liver extract is given at a level of 7–8 g. of hæmoglobin per 100 ml., reticulocyte increases of about 20% may be expected. The red-cell count rises at a rate of about 2,000,000 per c.mm. per week, though the hæmoglobin tends to lag behind. The most striking reticulocyte responses were seen in the rats prepared by operation A. In the more acute anæmia which follows operation B there is a greater reticulocytosis in the untreated animal; in these rats the reticulocyte percentage rose by a similar amount, but the higher initial count made the response less striking.

DISCUSSION

Several types of operation have been tried in these experiments. All of them may be followed by macrocytic anæmia, but only in the case of a 3-in. loop made to fill by peristalsis was there a high incidence of anæmia accompanied by a reasonably low mortality. We have made some experiments to determine the most useful site for the loop, and have found that the exact position is unimportant provided that it is in the upper or middle part of the small intestine. In a small group of animals, in which the loop was placed immediately above the cæcum, no anæmia has developed.

An unexpected feature of the animal anæmia was the large dose of liver extract necessary to produce a

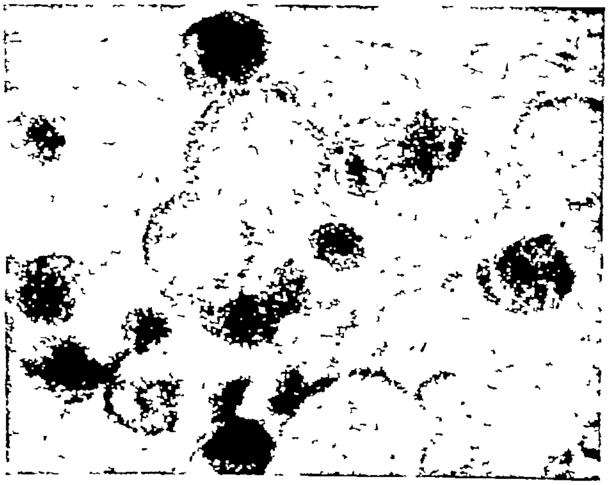

Fig. 9—Marrow smear from rat with macrocytic anæmia. (× 1166.)

remission. Our impression is that the size of the dose depends on the size of the loop and on the rapidity of onset of the anæmia, but in any case at least 0·1 ml. of anahæmin was necessary to produce a remission, and in some cases as much as 0·8 ml. The manner in which liver extracts produce their effects is unknown, and it may be that calculations based on the weight of the animal are unreliable. A further point is that possibly, in small animals like the rat, the life span of the red cell is much less than in man, and the need for hæmopoietic principle may be correspondingly greater.

The anæmia seen in these rats resembled in most of its features the anæmia observed in human cases of intestinal stricture or anastomosis, and probably the two conditions are produced by a similar mechanism. What this mechanism is, and what is the relation of anæmia of this kind to Addisonian pernicious anæmia, remains uncertain. A working hypothesis is that materials are formed in the stagnant loop which in some way interfere with the formation, absorption, or utilisation of hæmatinic principles, and experiments designed to test this hypothesis are already planned. Diarrhœa was not present, and no symptoms of neuropathy were seen. Fat-balance experiments and the results of examination of the nervous system will be reported later.

A good deal of experimental work in animals has been confused by the presence of latent bartonella infections, which become manifest after splenectomy. However, we have no reason to believe that our rats had bartonellosis, or that bartonella infections can be activated in so specific a way by the formation of a dilated blind loop of intestine. Perla and Gottesman (1932) reported that a dietary supplement of copper and iron in amounts of 0·1 and 1·0 mg. respectively daily protected rats from bartonella infection, and the diet for the present experiments included these supplements. Finally, bartonella infection does not respond to liver in this way.

We have also not yet had opportunity to discover how specific is the response to liver and folic acid in these rats. The only other material with which we have experimented is pantothenic acid, and this was without effect. We have published the results obtained to date because they have already been reported at scientific meetings in this country and have attracted a good deal of interest. They seem to offer the promise of a reliable method of assay of liver extracts. They certainly provide a preparation which should be of value in revealing the mechanism of pernicious anæmia and allied megalocytic anæmias, which at present seems so complicated and obscure.

SUMMARY

The formation of a blind intestinal loop in the rat causes a macrocytic anæmia which responds to treatment with liver extract.

The pathogenesis of this anæmia is not yet known, but it depends on dilatation of the blind loop, with accumulation within it of intestinal contents.

The technique described is likely to be useful in the bio-assay of liver extracts and in analysing the mechanism of pernicious anæmia and allied megalocytic anæmias.

We are greatly indebted to Miss A. Hogg, Miss B. Mallet, Miss C. Stayte, and Mrs. M. Bruce-Lockhart for their help in this investigation, which has necessitated much tedious work in the *care of the animals and in making blood* examinations.

ASSISTANT PROFESSOR OF PÆDIATRICS
UNIVERSITY OF ATHENS

In an address on tuberculosis in childhood, given t the Greek Pædiatric Society in February, 1946, w discussed two new forms of the primary complex (th pyuric syndrome and the form with intermittent fever and also described some associated manifestations i the central nervous system. We reported that 2 of ou cases developed convulsions with each rise of temperature. In 3 other cases we noted exaggerated reflexes *which at times reached the stage of ankle clonus.* Since such phenomena mean irritation of the pyramidal tr their presence in the course of an acute primary inf led us to fear that tuberculous meningitis was imminent. However, it fortunately did not follow. [illegible] of the cerebrospinal fluid (C.S.F.) showed occasional rise in tension but no other abnormality either in composition or in cell-count. The neurological signs gradually subsided with the regression of the fever, malaise, &c., and disappeared.

These cases have been succeeded in our experience by others, and a similar case in an infant has been described by Dr. Zervos, assistant professor of pædiatrics in Athens, in a thesis dated 1947. There seems to be no doubt that they represent meningism during the primary infection, and we believe the explanation is a serous reaction of the meninges during the hyperergic period of the disease.

The appearance of meningitic signs which do not g on to tuberculous meningitis is of both theoretical and practical importance. It supports the view that during the course of tuberculous infection in childhood a local *inflammatory reaction occurs on a specially* allergic ground. This meningeal reaction does not develop *clinically* beyond the stage of slight meningism, either because it is limited and remains in the stage of simple inflammatory reaction, or because the development of tubercles is also limited and does not spread. Laboratory findings show only "a slight degree of hydrocephalus due to oversecretion by the choroid plexus."

Lincoln[1] refers to this *type* of meningeal reaction, *with no changes* in the C.S.F. except *slight increase* in pressure and in cell-count, *but with tubercle bacilli present.* This means that the presence of the tubercle bacillus in the C.S.F. does not always imply the development of meningitis in its full form. We have had 2 similar cases under our care.

CASE-RECORDS

nvestigations.—Blood: red cells 3,800,000 per c.mm.; ite cells 13,500 per c.mm. (polymorphs 46%, lymphocytes %). Blood-sedimentation rate (Linzenmeier) 10 mm. ntoux reaction (1/10,000) + + +. C.S.F. (cisternal punce): under normal pressure, clear; protein 20 mg. per ml.; cells 8 per c.mm.; glucose 40–50 mg. per 100 ml.; orides 540 mg. per 100 ml.; tubercle bacilli present on ture. Urine normal. Radiographic examination of chest: ateral hilar adenitis.

Progress.—Pyrexia continued for 5 days, and then slowly osided. The patient was discharged after 15 days, clinically proved, with the diagnosis of tuberculous adenitis and ningism. He was followed up at home and seemed well. mbar puncture was performed on Feb. 26 (40 days after mission); the C.S.F. was normal in all respects, and on lture no tubercle bacilli were found. When seen four onths later, the child appeared perfectly well, and physical amination revealed nothing abnormal.

Case 2.—A boy, aged 2 years; only child. Parents althy, but an uncle with pulmonary tuberculosis had come live in the home a few days after patient's birth. Birthight 8 lb. 11 oz.; B.C.G. vaccination not undertaken; east-fed for six months. After the fourth month became ldly pyrexial, and during the previous week temperature e to 100–101°F, on which account he was admitted on rch 15, 1948.

Examination.—Nutrition poor, mucosæ pale. Tongue ated; tonsils slightly injected; liver just palpable; spleen larged 2 fingerbreadths below costal margin. Heart, lungs, d central nervous system normal. Lymph-glands not lpable.

Investigations.—Blood: red cells 3,500,000 per c.mm.; ite cells 12,600 per c.mm. (polymorphs 36%, lymphocytes %, large monocytes 4%, normoblasts 1–2%). Sternal ncture: no leishmania or malarial parasites. Mantoux action (1/1000) + +. C.S.F.: pressure slightly increased, ear; protein 20 mg. per 100 ml.; cells 1–2 per c.mm.; bercle bacilli not found on direct smear, but present on lture. Urine normal. Radiographic examination of chest: t hilar adenitis.

Progress.—Pyrexia persisted. General condition satistory; no vomiting or constipation. Patient complained ly once of headache. From four days after admission given eptomycin intramuscularly 0·15 g. four times daily for week; total dosage 4·5 g. After the first dose of eptomycin the temperature became and remained normal. scharged on March 26. Two and a half months later clinical dings normal. Parents objected to further lumbar puncture.

DISCUSSION

There seem to be two possible explanations for such ses as these: (1) tubercle bacilli circulate in the C.S.F. ithout there necessarily being a focal lesion with its linical sequelæ; or (2) the bacilli derive from a focus the meninges which is too small to cause clinical anifestations, does not enlarge, and eventually recedes nd disappears. Both explanations are feasible, but the econd seems to be the more likely.

This problem is connected with that of the clinical actions and laboratory findings in tuberculous meninitis treated with streptomycin, about which these rther questions have to be answered:

1. Why do some cases respond immediately to streptomycin, ereas others respond slowly, and still others not at all?
2. Why is clinical improvement sometimes not accompanied parallel change in the C.S.F., the abnormality of which rsists?
3. What is the criterion of cure (if we can speak of "cure")? oes it rest on the clinical condition, on laboratory findings, on negative results of culture for the tubercle bacillus?

In practice the most urgent question is the third; and e consider that the return of the cells and chemical state the C.S.F. to normal is more significant than a negative lture. In 2 cases of another series, where the patients were discharged from the clinic as "recovered," culture of the C.S.F. a few days before discharge was positive for tubercle bacilli; and yet six months later both children appeared perfectly well. Clearly streptomycin is *forcing us to review our earlier conceptions* of the pathogenesis and development of tuberculous meningitis.

SUMMARY

Two cases are described in which tubercle bacilli were isolated from the C.S.F., without accompanying manifestations of tuberculous meningitis.

Both patients, one of whom received streptomycin, survived, and they were well 4 and $2\frac{1}{2}$ months later.

In the C.S.F. tubercle bacilli may sometimes either (1) exist without any focal lesion in the brain or meninges; or (2) derive from a minimal meningeal lesion which resolves. The second explanation seems the more likely.

It is suggested that in assessing "cure" of tuberculous meningitis greater weight should be attached to chemical and cytological findings in the C.S.F. than to the results of culture for the tubercle bacillus.

ACCIDENTAL INTRA-ARTERIAL INJECTION OF DRUGS

(Concluded from p. 371)

DANGERS OF THERAPEUTIC OR DIAGNOSTIC INTRA-ARTERIAL INJECTIONS

Tragedies following the intra-arterial injection of therapeutic substances or contrast media for radiography have also been collected in the hope that they may throw some light on the pathology and indicate the treatment. Gangrene of the fingers has followed accidental injection of iodoxyl for pyelography (B. Johnson, personal communication); sodium tetrachlor-iodo-phenolphthalein for cholecystography (S. I. Levy, personal communication); iodides for arteriography (White 1935); diodone injected into the femoral artery for leg arteriography has ended disastrously (Maybury 1946); and ethanolamine injected into the femoral artery instead of into varicose veins necessitated a high amputation of the thigh (Medical Defence Union 1947).

Levin and McElroy (1944) have described a case of cerebrospinal fever with thrombosis of the right axillary artery, followed by gangrene of arm and forearm. The patient, who was at first unconscious, received therapeutic intermittent intravenous injections of sulphapyridine into affected arm. Levin and McElroy agree that the gangrene is difficult to explain but admit that intra-arterial injection was a possibility. The pH of sulphapyridine is about the same as that of thiopentone, and its destructive effect, when it is injected in the region of nerves or into the spinal canal, is known to have caused several tragedies (Roberts 1942).

Gangrene of the hand has followed the injection of quinine. I am indebted to Mr. Frank Nicholson for the following case-report:

A patient with malign tertian malaria was admitted more or less in coma into a hospital in Tripoli. Intravenous quinine was required, and in the ensuing struggle the left brachial artery was probably punctured. I was asked to see the patient next morning, when the left hand was cold, white, and anæsthetic up to the wrist, and the radial pulse was absent. Exploration under general anæsthesia showed a hæmatoma beneath the deep fascia. The brachial artery was narrowed to the size of the radial artery, and there was a definite needle puncture in its anterior wall. Two inches of brachial artery was resected; local and stellate ganglion procaine block. The ultimate result is uncertain, for Mr. Nicholson embarked next day for Sicily; but I understand from a colleague attached to the same division that amputation through the forearm became necessary.

Sir Philip Manson-Bahr informs me that he has heard of no similar tragedy with quinine, nor have the Army and other tropical disease authorities. Schmuttermayer (1936) records a "burning sensation in the hand" following intramuscular quinine on the outer side of the mid-arm; radial nerve-palsy followed, but the symptoms suggest some intra-arterial injection as well. "Malarial gangrene" of the foot, in a previously healthy man of 42, has been recorded (Lee 1937); but this complication has ensued usually only in neglected cases (Manson-Bahr, personal communication). Samuels (1945), describing malarial gangrene, states "it is usually caused by thrombosis of the arteries—the brachial artery is often involved"; such accidental intra-arterial injection may have been overlooked.

Extramural spilling of neoarsphenamine is well known to be followed by local sloughing. The intra-arterial accident seems to have been rare, for Dr. V. E. Lloyd, who is in charge of a V.D. clinic at Guy's Hospital, writes in a personal communication (1945): "No instance has happened in my hands or in the hands of anyone working with me. I have never heard the 'accident' referred to at meetings of the Medical Society for the Study of V.D. throughout the last twenty years."

Walsh and Wyatt (1945) have recorded a case in which arsphenamine hydrochloride ('Mapharsen') caused flushing and nothing else. I have traced a case where gangrene followed the accidental injection of arsphenamine ('Salvarsan'); the amputated forearm is in St. George's Hospital museum:

> A man, aged 50. "No difficulty was noticed with the injection, and no unusual symptoms occurred at the time. After a few days pains started in the hand, which became swollen, with brawny œdema extending 3 in. above the elbow. The diagnosis of brachial artery thrombosis was made and the arm later amputated. A recent thrombus filled the brachial artery from a point 3 in. above its bifurcation downwards. Section showed slight endarteritis. There was no evidence of wounding of the artery or escape of salvarsan into the tissues."

Gammel (1927) has recorded extensive gangrene of the buttock following the "intramuscular" administration of bismuth. He reviews the literature, which includes several such cases, and shows that the effects were due to the injection into the inferior gluteal artery.

> A particular feature of one of the cases he describes was the development of foot-drop. This neurological information is important, for the inferior gluteal artery is the main artery of supply to the sciatic nerve, and experimentally Okada (1905) showed that ligature of the inferior gluteal artery of a rabbit was followed by paralysis of the sciatic nerve.
>
> This case is thus the first clinical confirmation of the profound effect of a single regional vessel on its nerve of supply, and provides the evidence that Adams (1942), in an exhaustive paper on the blood-supply of nerves, was seeking. It also appears to confirm the view already put forward that some of the effects in the thiopentone cases are due to thrombosis spreading to the vessels of supply of the major nerves of the forearm.

The hazards of the use of sclerosants during anæsthesia, as in the treatment of varicose veins, has been receiving increasing attention in recent years. Anæsthetists need to be acquainted with the fact that under general anæsthesia, with the limb immobile, injection of sclerosants into the superficial veins may be followed by thrombosis of the deep veins, owing to the numerous deep connecting branches. The pulmonary embolus, occasionally following the Trendelenburg ligature operation, is believed to be derived from this, rather than small clot remnant at the saphenous ligature stump.

The danger of such thrombosis is greatest if injection is done with the patient under general anæsthesia; if the operation is done under local anæsthesia, immediate muscle movement will sweep away the sclerosant. Those associated with medicolegal societies also know th arteries round the ankle have been accidentally in (D. H. Patey, personal communication).

Gangrene of the hand and forearm has followed the injection of 'Myanesin' (Ogilvie et al. 1948), a particu feature of the case being the presence of good ra and ulnar pulses palpable through the gangren tissues. Ogilvie et al. demonstrated, in vitro, t "curdling" colloid precipitate effect of the admixt of blood and myanesin; with intra-arterial inject showers of coagula are swept into the distal stream block, in mechanical fashion, the distal minute arter

Numerous tragedies have followed the use of cont media for arteriography, and Wagner (1944), report a case following the use of iodoxyl has given admirable and comprehensive account of the literatu

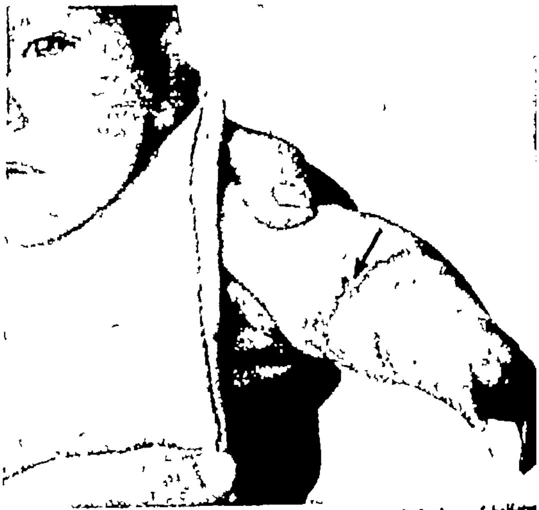

Fig. 21—Gangrene following "intravenous" infusion of half-str Hartmann's solution plus 5% glucose in a baby, aged 6 m admitted with diarrhœa and vomiting. Cannula had been intr with difficulty into "vein" (indicated by arrow) on radial asp forearm. Oscillation of fluid in drip chamber had been noted, b ceased on release of strapping holding arm to splint. (Case consultation.)

Lambret (1935), Dos Santos (1935), and Leclerc (have all given accounts of such tragedies. Le (1935), in the study of one such case after iodoxyl child (and many of the tragedies have been in childr found a recent thrombus in the brachial artery, observed that (as in some of the thiopentone cases) lesion could be found in the vicinity of the site puncture." He did some experiments on the effect irritants on vessels of bats' wings, the tongue of ne and mesenteric vessels of rabbits, and concluded "the normal rhythm between the arterioles and ve side of the capillary loop was disturbed. That le gangrene." It is well to observe that, in this coun diodone ('Per-Abrodil' and 'Pyelosil') has in re years been used for arteriography in hundreds of ca the injection has been frequently repeated, and result of my repeated inquiries from fellow wor appears to indicate that these media are absolutely

Gangrene of the hand and forearm has followed intra-arterial injection of Hartmann's solution in a b aged 6 months (fig. 21). The undoubted "intraveno infusion of concentrated plasma, under pressure, the saphenous vein, at the ankle, in infants with diarrhœa and vomiting, has ended in gangrene of leg. Two such cases have been seen by M. Bo and D. J. Waterson (personal communication). Th the subject of their particular study at the moment. exact pathogenesis being as yet uncertain. Two c have also been observed in infants where localised patch gangrene, in the thigh and leg well above edle site, followed the usion of plasma under ssure.

Wallace and Richards 48) have noted also, Army "practice" nsfusions, the delayed elopment of ecchy- tic areas in the arm ll above the needle e. They suggest t it is due to intense sm of the veins ining the biceps cle. with rupture of ne of the tributaries.

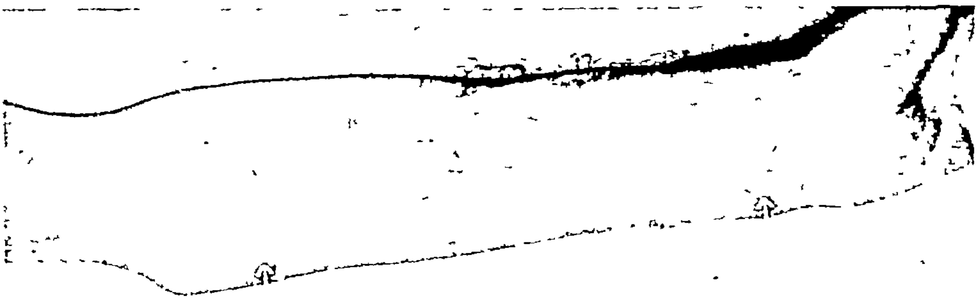

Fig. 24.—Ulnar artery subcutaneous near elbow and then proceeding below deep fascia. Vein-like appearance is shown; pulsation was evident only on close observation.

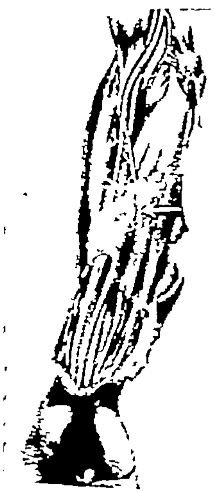
e segmental distribution of these skin patches is particular interest in view of Wood Jones's (1948) ment that it is insufficiently appreciated that limb has a number of self-contained functional ns units. and abundant arteriovenous com- ications in these areas to meet the circulatory rgency demands. It is probable—indeed to be cted—that such arteriovenous communications ld be relatively larger in the infant and thus explain retrograde filling, under pressure. of the arterial : certainly it is difficult to explain the intra-arterial mbotic clot found in these "intravenous" tragedies fants on any other basis.

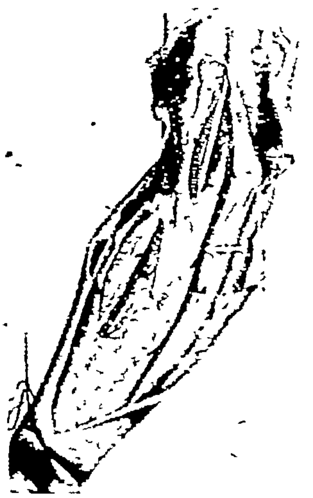
ANATOMICAL VARIATIONS AT THE ELBOW

hese can be best appreciated by a brief reference embryological development. The limb buds are pervaded by a capillary network; during the sixth k of fœtal life the primary arterial channels are laid n. and there is developed a main. or axial. artery ch persists as the subclavian, axillary. and brachial ries. In the forearm most of the axial artery under- s suppression. and its primary course is represented the branch of the interosseous artery accompanying median nerve. "The radial artery arises at first higher level than the ulnar artery, but later establishes nexion with the main trunk near the site of origin the ulnar. and the upper part of its original stem appears" (Gray 1938).

uain's (1844) careful study of 451 dissected arms vides a comprehensive account of the possible varia-tions. High division of the brachial artery—i.e.. above the elbow-joint—takes place in 1 out of 10 arms: and, contrary to the usual teaching, in only a third is such peculiarity bilateral. When the division is high, the ulnar artery almost invariably reaches the distal part of the arm by passing superficially to the flexor group of muscles (10% incidence). In its downward path it may hug the radial branch in the elbow area, but at times it takes a medial sweep to lie well apart (fig. 23). In its downward superficial course the ulnar artery may occupy one of three different positions: (1) subfascial all the way down (fig. 22): (2) subcutaneous in the elbow area and then below the deep fascia (fig. 24); or (3) subfascial in the upper part of the forearm. then subcutaneous. and in the distal third of the forearm subfascial again.



22



23

. 22.—Ulnar artery (arrow) in subfascial plane. High division of rachial artery is more usual finding when vessel pursues this course. From Quain 1844.)

. 23.—Ulnar artery (arrow) passing down subcutaneously. Note igh brachial origin and medial sweep at elbow.

When the ulnar artery pursues this superficial course, its volar interosseous branch comes off the radial division. This fact is of the utmost importance; for, if the brachial vessel divides high, retrograde injection into the aberrant ulnar branch is unlikely to reach the brachial artery, unless the circulation has been temporarily cut off. The interosseous branch, coming off the radial division, is therefore unlikely to suffer in any thiopentone thrombosis, and via this vessel the flushing and dilution of any ulnar injected thiopentone can continue. It is also to be noted that, when the course of the ulnar artery is superficial, the vessel is usually smaller, and compensatory enlargement is invariably found in the radial division. This will also enable the freer flushing of any irritants carried by the ulnar vessel. Such superficial ulnar vessels are derived from the vasa aberrantia and. like other superficial vessels, have a fuller nerve-supply than have the deeper branches, and are more readily thrown into spasm. The latter fact explains why, in cases 10 and 12. there has followed "immediate thrombosis and thickening" after injection of the superficial ulnar artery. The relationship of these vessels to the veins of the forearm are shown in figs. 25 and 26.

Arms have been examined to see if such abnormalities can be determined during life. The vulnerable superficial ulnar artery is often encountered. I. Jacobson, after a study of 200 arms of soldiers, informs me that in 25 the arteries near the antecubital fossa were in such a position that they could easily be inadvertently punctured when an injection was given (fig. 27). There were three abnormal superficial ulnar arteries in this group. At a small meeting where this was discussed, 4 out of 25 doctors present had subcutaneous ulnar arteries. Quain (1844) made this observation in the living subject.

Hyperextension of the elbow straightens the normal tortuosity of the brachial artery and fixes it for easier injection; this, therefore, requires particular care.

Pulsation in the normal young healthy person is not easily seen, and it is unjust criticism to comment that such thiopentone tragedies would not have happened if the anæsthetist had spent a few moments looking for these vessels. Lewis (1945) comments on the forearm vessels:

division that amputation through the forearm became necessary.

Sir Philip Manson-Bahr informs me that he has heard of no similar tragedy with quinine, nor have the Army and other tropical disease authorities. Schmuttermayer (1936) records a "burning sensation in the hand" following intramuscular quinine on the outer side of the mid-arm; radial nerve-palsy followed, but the symptoms suggest some intra-arterial injection as well. "Malarial gangrene" of the foot, in a previously healthy man of 42, has been recorded (Leo 1937); but this complication has ensued usually only in neglected cases (Manson-Bahr, personal communication). Samuels (1945), describing malarial gangrene, states "it is usually caused by thrombosis of the arteries—the brachial artery is *often involved*"; *such accidental intra-arterial injection* may have been overlooked.

Extramural spilling of neoarsphenamine is well known to be followed by local sloughing. The intra-arterial accident seems to have been rare, for Dr. V. E. Lloyd, who is in charge of a V.D. clinic at Guy's Hospital, writes in a personal communication (1945): "No instance has happened in my hands or in the hands of anyone working with me. I have never heard the 'accident' referred to at meetings of the Medical Society for the Study of V.D. throughout the last twenty years."

Walsh and Wyatt (1945) have recorded a case in which arsphenamine hydrochloride ('Mapharsen') caused flushing and nothing else. I have traced a case where gangrene followed *the accidental injection* of arsphenamine ('Salvarsan'); the amputated forearm is in St. George's Hospital museum:

> A man, aged 50. "No difficulty was noticed with the injection, and no unusual symptoms occurred at the time. After a few days pains started in the hand, which became swollen, with brawny œdema extending 3 in. above the elbow. The diagnosis of brachial artery thrombosis was made and the arm later amputated. A recent thrombus filled the brachial artery from a point 3 in. above its bifurcation downwards. Section showed slight endarteritis. There was no evidence of wounding of the artery or escape of salvarsan into the tissues."

Gammel (1927) has recorded extensive gangrene of the buttock following the "intramuscular" administration of bismuth. He reviews the literature, which includes several such cases, and shows that the effects were due to the injection into the inferior gluteal artery.

A particular feature of one of the cases he describes was the development of foot-drop. This neurological information is important, for the inferior gluteal artery is the main artery of supply to the sciatic nerve, and experimentally Okada (1905) showed that ligature of the inferior gluteal artery of a rabbit was followed by paralysis of the sciatic nerve.

This case is thus the first clinical confirmation of the profound effect of a single regional vessel on its nerve of supply, and provides the evidence that Adams (1942), in an exhaustive paper on the blood-supply of nerves, was seeking. It also appears to confirm the view already put forward that some of the effects in the thiopentone cases are due to thrombosis spreading to the vessels of supply of the major nerves of the forearm.

The hazards of the use of sclerosants during anæsthesia, as in the treatment of varicose veins, has been receiving increasing attention in recent years. Anæsthetists need to be acquainted with the fact that under general anæsthesia, with the limb immobile, injection of sclerosants into the superficial veins may be followed by thrombosis of the deep veins, owing to the numerous deep connecting branches. Gangrene of the hand and forearm has followed intra-arterial injection of *Hartmann's solution* in a b aged 6 months (fig. 21). The undoubted "intravenou infusion of concentrated plasma, under pressure, i the saphenous vein, at the ankle, in infants with sev diarrhœa and vomiting, has ended in gangrene of leg. Two such cases have been seen by M. Bod and D. J. Waterson (personal communication). Thi the subject of their particular study at the moment. exact pathogenesis being as yet uncertain. Two ca have also been observed in infants where localised s patch gangrene, in the thigh and leg well above thesia such anastomoses relax. Clinically also, cervical sympathetic block in one of the cases was followed by immediate vasodilatation, which suggests that the vessel is kept closed by a reflex whose efferent arc passes via *the sympathetic ganglia. This observation* needs confirmation; for, if true, it gives us a rational basis for the management of the finger gangrene.

The pathological material available to me has been in the main from thiopentone cases. Study of the tragedies following other drugs and therapeutic media indicate, however, that the circulation may be finally arrested by different mechanisms, several acting at the same time. These may be summarised as:

(1) Arterial thrombosis—most of the thiopentone cases.

(2) Arterial or distal arteriolar spasm.

(3) Extensive diffuse venous thrombosis, as after the accidental retrograde injection of sclerosants into the deep veins. I have seen diffuse venous thrombosis, in traumatic injuries, lead to limb gangrene, the arterial tree being patent and the major vessels not in agonal spasm.

(4) Extensive venous spasm. I have not seen gangrene per se follow this, but it may be a contributory cause of limb death. How great may be the peripheral resistance to arterial inflow in this type of spasm is well shown by Humble and Belyavin (1944); a pressure of 300 mm. Hg could not force the fluids into the veins.

(5) Mechanical blocking due to protein flocculation or drug precipitation, as in the concentrated plasma and myanesin cases.

(6) Arteriovenous communications enabling the retrograde spilling over of intravenous fluid into the arterial circuit. This is especially likely to happen if the fluid is given under pressure; it has been suggested as the possible explanation for leg gangrene following intravenous infusions in children.

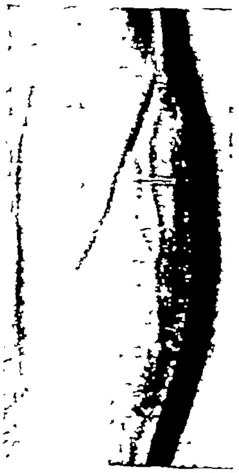

Fig. 27—Veins distended with rubber band. Arrow indicates superficial ulnar artery. Gliding of needle to enter median basilic vein may lead to puncture of artery.

There is need for experiments on animals to discover the pathological events; large animals are to be preferred, for in small animals such as the rabbit the vessels are too readily thrown into spasm by any handling and confuse the tissue. Such *facilities have not been available to me.*

TREATMENT

Anticoagulants

It would require courage on the part of the anæsthetist to order the abandonment of the operation. Obviously that is the measure most desirable, for the formation of a thrombus indicates that there is urgent need for anticoagulant therapy—heparinisation of the patient. Such anticoagulant therapy may need to be long-continued, for the case-records indicate that thrombosis may come on as late as the eighth, tenth, or fifteenth day. To combat late thrombosis dicoumarin is best; its action, however, is delayed for 48 hours, and until then heparinisation must be continued. Such anticoagulant therapy may be inadvisable after some operations, but it is usually considered safe to start heparinisation after 2–3 hours; my experience is that, in the routine operation where adequate hæmostasis has been possible, heparin may be given even earlier. The early doses of heparin should be generous, for it will not be of much value to find at the end of, say, four hours that the clotting-time has not been raised, and that further heparin in increased dosage is necessary. I suggest in the adult 15,000 units at least as the initial dose.

This larger dosage is also important, for different batches seem to vary in their potency and in their "toxic" reaction (Brown 1946). Heparin is best administered as a saline drip into the tubing of which the nurse can inject the repeated doses (Medical Research Council 1944). Humble's cannula is a suitable alternative method for intermittent administration.

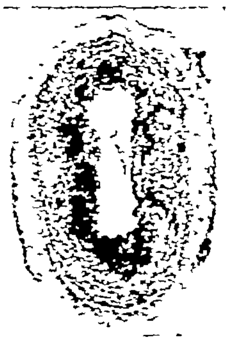

Fig. 28—Radial artery (case 9): intima thickened, and lumen filled with fibrin clot, leaving channel patent.

My experience is that intermittent administration is not adequate for the threatened arterial thrombosis; the clots form during the *night* ("free" period). Experimental studies (Kiesewetter and Shumacker 1948) confirm that a constantly prolonged coagulation-time is more desirable and superior, particularly as regards clotting in the smaller arteries.

If the anæsthetist feels certain that injection has been intra-arterial, it may be well worth inviting the surgeon to expose the vessel immediately and to inject heparin *intra-arterially. Intra-arterial* procaine, as first introduced by Goyanes in 1912, has been suggested, but its local action is evanescent unless a tourniquet is used; this could not be countenanced after thiopentone. Intra-arterial procaine has not been effective in the intense spasm that has followed the forgotten tourniquet and the crush *injury* (personal communications). Local injections of procaine round the artery were tried in two of the cases, with no effect; it has almost always *failed to release spasm of a major vessel secondary to* trauma.

Brachial-plexus Block

The anæsthetist should probably do a brachial-plexus block immediately. That should give the maximal vasodilatation in the hand and release the tone of the arteriovenous shunts on the fingers. I suggest brachial-plexus block rather than sympathetic block, because the anæsthetist is conversant with it, whereas sympathetic block, in my hands, is not so easy or so certain as the textbooks indicate. Brachial-plexus block will anæsthetise the vasoconstrictor fibres relayed from the sympathetic ganglia to the hand and forearm, the area which concerns us most; the periarterial sympathetic plexus supplying the upper portion of the brachial artery will not be affected, but this is not important. The forearm vessels will be affected, for it is now generally agreed that the vasoconstrictor nerves to the vessels leave the main nerve-trunks at short intervals to supply corresponding lengths of vessels. As Macintosh and *Mushin (1944) have pointed out, brachial-plexus block* is followed by some degree of Horner's syndrome in 50% of cases. *That must indicate* spread of the solution and blocking of the sympathetic ganglia, or its rami, as well.

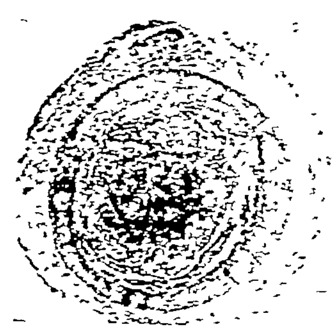

Fig. 29—Brachial artery (case 5): recent thrombosis and widespread superficial necrosis of intima.

"It is unusual for normal arteries to show visible pulsation, and then it is but slight . . . the volume change is almost negligible and only noted when the arterial wall is pressed on."

PATHOLOGY

Thiopentone in 2·5% solution has a pH about 10·4–10·6 by the glass-electrode method (Tabin cited by Adams 1944). As Adams points out, the derivatives of thiobarbituric acid are rather unstable, the disintegration products including, among others, amides and acetyl urea. To prevent hydrolysis and separation of free acid, commercial preparations contain also, as buffer, sodium carbonate 6% by weight. Thiopentone is thus a strong alkaline irritant.

An artery, with its high muscle and elastic content, is obviously less distensible than the vein, and intra-arterial injection may thus be supposed to trap the thiopentone longer. Yet arteriography shows that a hypertonic solution (50% of diodone) rapidly injected passes through the limb within a few seconds. That period may, however, be sufficient for thiopentone to exert its action. Stretching of the arterial wall by rapid injection may be supposed to lead to arterial spasm and trapping of the solution. Arteriography, however, shows that any spasm of a major vessel produced by such stretch can be but momentary; for, if the needle is retained within the vessel and the injection repeated, the full anatomy of the tree is again reproduced. The radial artery is, however, an "irritable" vessel, and occasionally, after arteriography, may go into spasm, with loss of pulse for several hours, but with no ischæmic effects. Clinical experience shows that the superficial ulnar artery is similarly subject to spasm. The intra-arterial injection of thiopentone, except in the case of the ulnar arteries, was not followed by spasm of a major vessel, for the pulse continued at first in full volume.

Thrombosis was the essential pathological lesion; its onset was immediate in the ulnar-artery cases: in one evident after 50 min., in another within 6 hours, and in three it appeared to become complete on the eighth, tenth, and fifteenth day after the injection. Damage to the intima, due to puncture of the vessel, suggests itself, at first thought, as responsible for the thrombosis; but this does not follow arteriography, even when repeated, and when the intima can be presumed to have been scratched. Leriche (1945) reports a case where the femoral artery was punctured 30 times (with tourniquet on) for mercurochrome injections, with no subsequent local thrombosis. Suture of a vessel, including all its coats, is not followed by thrombosis, even in the non-heparinised patient. The small intra-arterial hæmatoma of the vessel wall does not alone cause spasm of a major vessel, as has been said to follow in the traumatic case (Cohen 1944). We can only conclude that the arterial intima appears to be particularly sensitive to thiopentone and solutions of high pH; for it tolerates extremely well hypertonic solutions used for arteriography and various therapeutic substances.

Damage to the intima is the precipitating factor, and microscopy indicates that an aggregation of platelets over the site of the damage forms the starting-point of thrombosis. Where late thrombosis has set in—eighth and tenth day (cases 9 and 11)—histological sections showed that the lumen may be lined with a thick layer of fibrin with a narrow channel through it (figs. 28 and 29); this means that even if the pulse is felt it gives no indication of the volume of blood-flow.

A thrombosis usually extends proximally no higher than the origin of the major collateral vessel next above the site of damage. As already remarked, the high thrombosis in these cases can only be explained by high ascent of the injected solution. This high injection against the flowing arterial stream, as arteriography and experiment indicate, is only possible if there has been arrest of the circulation by clavicular or other co of the subclavian or axillary artery, or failure to releas the assistant's pressure or the rubber-band "venous" tourniquet.

Shunting of the drug into the skin has already been explained as responsible for the sloughing or discoloured patches of skin. The distal forearm a finger are affected according to the distribution of thiopentone. Excretion of thiopentone into the mus will lead to an outpouring of fluid, as with any irritat substance. The exact physico-chemical process wh follows this is still a matter of argument, and Cam (1946) has pointed out that we do not yet know whet it is due to the loosening of the cement substan binding cells together, or a physical alteration in surface membrane lining the endothelial cells.

Where the vessels of supply to the muscles h completely thrombosed, muscle death has followed. T nerve ischæmia following thrombosis has also been sho to be responsible for the nerve effects. Where separ fingers have died, complete blockage of the dig vessels by thrombus has obviously been the cau the clinical evidence of this is the fact that these fing developed no œdema.

Where recovery took place, the digital vessels co only have been in spasm, and these fingers subsequen became œdematous. There is no evidence in man t continued spasm leads to arterial thrombosis.

We still have to explain why terminal gangrene of finger-tips was a feature in several cases; for, as Le (1934) has shown in his studies on Raynaud's dise the entire length of the digital artery is always affe in such spasm, and gangrene of the whole finger is expected. We cannot overlook the fact that in so the cases the extent of finger gangrene correspo to the area where Grant (1938) has shown the arte venous anastomoses to be most abundant. Th anastomoses have thickened muscle walls and are kn to be particularly well supplied with vasomotor nerv they are maintained in a state of rhythmic contractil which has a milking effect and adds impetus to circulation on the venous side, which, in the fing has no "pumping" muscles to promote it. Clotting the venous loop will thus be favoured, if intense sp due to the irritant, is maintained in these anastom Animal experiment shows that during sleep and an

ead of thrombosis. It is believed that the arterial lsation plays a not inconsiderable part in driving blood ng the accompanying vein (Clark 1939); since the ombosis is so extensive, elevation will compensate this lack of pulsation.

he importance of assisting the lymphatic drainage by vation, to cope with the œdema of hand and forearm these cases, must also not be overlooked. Courtice 46) in studies of chemical warfare, and Drinker d Yoffey (1941), in studies of burns, have shown, cannulating the lymphatics experimentally, how great y be the return of lost fluid via this circulation.

mperature of Limb

The limb should be wrapped in a sterile towel and vered with wool: it should not be kept cool or exposed the air. Such cooling increases arterial vasoconstriction, d the veins and venules contract as a direct response cold. Prevention of heat-loss from the limb is portant: as the oxyhæmoglobin dissociation-curve ows, oxygen is poorly released at lower temperatures. ith mild warmth, venous tone is diminished and terial pressure is transferred to the venous side more mpletely than when tone is high (Bowers et al. 1945). xcessive heating of the limb with a cradle or by other eans must, however, be avoided, for it is well known at the metabolism of the cells is thus stepped up, creasing their oxygen demands. Pochin (1943) has own that, if the blood-supply to a rabbit's ear is bstructed by placing a wooden plug in the external ar and binding this with wide elastic tubing, œdema bsequently develops on release of the circulation; he extent of gangrene that develops in the ear will epend not on the amount of œdema but on the temperature of the room in which the rabbit is allowed to recover. n a warm room (88°F) gangrene is a common sequel, hough the œdema may be no greater.

Vasodilators

Papaverine, alcohol, aspirin, and other anti-spasmodics have been used in these thiopentone cases with no dramatic improvement. Such measures may be tried: but it is well to note that Davis et al. (1943), after experiments in both normal persons and patients who had recovered from injuries to fingers following severe cold, concluded that "contrary to the general accepted action, as reported in textbooks, none of these drugs (amyl nitrite, nitroglycerin, alcohol) cause any elevation of the temperature in the distal parts or dilatation of the capillary loops."

Experimentally, Laufman and Method (1947) have shown papaverine hydrochloride to be effective in releasing the residual vasospasm following gut strangulation: it is thus reasonable to use it. Intravenous ether 5% in 5% glucose—1 litre dosage—may also be tried.

Surgical Measures

When immediate exploration has not been done, the limb needs most careful watching—as if it were an acute intestinal obstruction—and the decision about exploration must be made within six hours. If operation is decided on, and the patient is already heparinised, an interval of two or three hours is necessary; but the use of protamine as a direct antidote to heparin, or a blood-transfusion, may allow earlier operation; the clotting-time will be a guide. The operation of choice is probably incision of the vessel and extraction of the clot. The vessel should preferably be opened well proximal to the injection site, so that the ultimate suture line of the vessel will not lie within the damaged area. The clot may be extracted with forceps or by aspiration. Experience with emergency embolectomies indicates that, if exploration is not early, the clot is adherent to the vessel wall and suction cannot aspirate it. I have had occasion, in this type of case, to incise the vessel in two of the distal branches and remove the clot by proximal syringing and flushing. This may be a useful expedient in some of the thiopentone cases. A distal intra-arterial injection of heparin should always be given at the time of the operation. After such manipulation of the vessel suture may be difficult, and the attempt to remove the clot may have mutilated the suture line. The operator may be tempted to tie the vessel; but it should be borne in mind that a glass cannula will allow the stream to continue if the patient is heparinised. The cannula may be removed three days later, and will, in the meantime, have given a good stream down and prevented clotting on the damaged intima (Mustard 1946, Cohen 1946b).

I am by no means certain of the value of immediate arteriotomy. The results after brachial embolectomy have caused some dissatisfaction, and opinion in this country no longer whole-heartedly favours it. B. G. Maybury (personal communication) declares, "the best treatment for a brachial embolus is sympathectomy." It may therefore be sufficient to heparinise the patient and try to achieve "medical" sympathectomy by measures such as reflex heating and tetraethyl ammonium chloride. The latter is said to have a selective autonomic block action in 500 mg. dosage (Ballantine 1947), and a well-marked increase in peripheral blood-flow is obtained, despite the generalised vasodilating effect. The associated well-marked fall of blood-pressure is the obvious disadvantage.

Arterectomy (excision of a segment of the vessel as practised in some of the cases, has to my mind no advantage; excision of the entire bifurcation ("triple ligation") usually ends disastrously and should be avoided (Maybury 1946). There is no evidence for the theoretical view that clotting in a vessel holds the collaterals in "reflex spasm" and that arterectomy will release such spasm (Cohen 1944, Lewis 1943).

Late surgical intervention does not seem worth while; all the cases in which late exploration was done fared badly. In view of the extensive thrombosis, operation could only prove of value if a full flushing by multiple arteriotomies and subsequent heparinisation of the patient could be practised. There is as yet no clinical experience for this: and, since microscopical sections show that the intima is severely and extensively damaged, further clotting is likely to take place. In children especially such late operations seem inadvisable. Gross (1945), who has made a close study of embolic infarction in children, emphasises that "occlusion of the large artery in the child at first seems incompatible with the survival of the limb"; yet it is remarkable what a first-class result conservative measures produce.

PROPHYLAXIS

Various suggestions have been made, of which most anæsthetists are aware: spending a moment and palpating and looking for arterial pulsation (Minnitt and Gillies 1944); the selection of a vein outside the cubital fossa or, even better, the almost constant vein over the dorsal and lateral aspect of the radius; and injection of a small quantity of thiopentone and waiting to see if the patient develops pain or not. A knowledge of the abnormalities of the arterial tree on the front of the elbow-joint is now a sine qua non to the anæsthetist. Avoidance of vigorous extension of the elbow, seeing that the venous tourniquet is not too tight, and the insistence on a good light are additional necessary precautions. "An emergency prepared for ceases to be an emergency" is a maxim that might well be engraved on the thiopentone ampoule.

SUMMARY

Eight unrecorded cases of catastrophic results following the inadvertent intra-arterial injection of thiopentone are described; five of these subsequently ended in forearm or arm amputations.

Posterior sympathetic block is not without danger. In case 2 the lung was punctured in the heparinised patient, causing severe hæmoptysis. It is also easy to insert the needle into the dural sheath along the nerve-trunks and to inject the fluid into the spinal canal. I am aware of several tragedies which have not been recorded. Cyriax (1937) in a report on observations made at Leriche's clinic, reported one such collapse; this followed what was believed to be accidental injection into the vertebral artery. Mackey and Scott (1938), discussing the infiltration of the stellate ganglion in apoplexy, describe a case where immediate respiratory paralysis, lasting 30 min., followed such injection "into the vein." Arnulf (1947), in a book on stellate-ganglion block, describes several such tragedies and alarming incidents, which he, however, regards as "exceptional."

The march of events is well shown in a note sent to me by an anæsthetist who tried sympathetic block in one of the thiopentone cases:

> "The patient lying prone, a needle was inserted 2½ finger-breadths lateral to the space between the spines of *C7 and T1.* The patient complained of paræsthesia in the arm; and, after tests for the aspiration of blood and cerebrospinal fluid, 15 ml. of 1% procaine, without adrenaline, was slowly injected.
>
> "There was some complaint of pain in the arm during the injection and, at the end of this, of nausea. He was turned on to his back and found to be unconscious. Respiration ceased, the pulse deteriorated and disappeared. Nikethamide 1·5 ml. was injected intravenously, artificial respiration begun, and oxygen and carbon dioxide administered.
>
> "Patient's condition being grave, the surgeon injected 1·5 ml. of nikethamide into the heart. Almost at once the pulse returned, very full and rapid, and a further 1·5 ml. was given intramuscularly. The time between the cessation of the heart and recovery was 1½–2 min.
>
> "Respiration did not return, and artificial respiration was continued. While this was proceeding, patient's pupils, which had been large and eccentric, became smaller, there were roving eye movements, and his facial muscles above the mouth began to twitch. It was 20–25 min. before respiration restarted, and during this time artificial respiration was continued.
>
> "Movements of the mouth and face now became more pronounced, and there was also cyclical twisting of the head from side to side. The legs were spastic, no jerks could be elicited, and plantar reflexes were absent.
>
> "About 15 min. after the restart of respiration, the picture was that of a cerebral catastrophe; patient's movements became more pronounced, and he was soon throwing himself about the bed most violently, groaning and coughing, with his facial and neck muscles moving. Sedation being imperative, morphine was given.
>
> "Three and a half hours later he was quieter but still tossing his head and unconscious. Four hours after the injection he was far more tranquil and, when spoken to, appeared to understand but could not talk or indicate by gesture that he understood. He now reacted for the first time to painful stimuli—i.e., turned his face away from a pinprick. The legs had become flaccid. The right plantar response, which had been extensor, was now flexor; the left still dubious.
>
> "Seven hours after the injection he was awake, answered questions normally, and complained only of a little nausea. The legs were of normal tone, with the left leg possibly slightly more spastic.
>
> "Subsequent convalescence was complicated by auricular fibrillation (confirmed by cardiologist). A week after the original injection the pulse rhythm had returned to normal."

The brachial-plexus block should probably be repeated at the end of the operation, for a report on one of the cases indicated that its effect lasted less than 4 hours. Amethocaine, because of its long-continued action, should form part of the anæsthetic solution. Brachial-plexus block cannot be repeated after heparinisation, for should the subclavian artery be pierced—always a minor hazard with this procedure—serious hæmorrhage might follow.

General Anæsthesia

Should the operation have to continue, the choice anæsthetic is important. General anæsthesia removes vasomotor tone from peripheral blood-vessels as effectively as does blocking of sympathetic nerves (Abramson 1944). Such peripheral vasodilatation should theoretically cause a steep fall in blood-pressure, an there is a rise of sympathetic tonus in other regions, suc as the great splanchnic area, which compensates an maintains the normal level (White 1935). Craig et a (1932), investigating the thermal changes in the limb during full anæsthesia, found a rapid rise of temperatu in the skin of the hand, with no additional increase nerve-block, indicating complete release of sympatheti tone. Scott and Morton (1930) showed that with nitrou oxide there may be vasoconstriction during the perio of struggle, and it is thus not a suitable anæsthetic f these cases. Cyclopropane has, as regards the circulatio some advantages. Waters (1936) has shown that i anæsthetic concentration it relaxes the peripheral bloo vessels, and Abramson et al. (1941) showed that the was quadruple maximal increase in flow almost immediately after the cyclopropane anæsthesia was begu Deep anæsthesia is not, however, desirable; for, according to experimental work by Mann et al. (1935), th increase in blood-flow in the peripheral arteries, a measured by thermostromuhr, falls to less than 20% with deep anæsthesia, as compared with the 64% rise with light surgical anæsthesia. The fall of gener blood-pressure with deep anæsthesia will affect th blood-flow through the limb.

Morphine and Sleep

Adequate quantities of morphine are required t relieve pain—Goetz (1943) and Wilkins et al. (19 have shown that painful stimuli will cause inte peripheral vasoconstriction—and to relax vessel spas (Learmonth 1946). Sleep inhibits vasoconstrictor tone and during sleep, in the normal person, full periphera vasodilatation is obtained. This has been confirmed b taking thermocouple leads from the toes (Ingram 1936

Forcing the Collateral Circulation

The patient should be kept warm and an attempt mad to force the collateral circulation by immersion opposite limbs in hot water (110°F) or by using a h cradle over the rest of the body. The warmed blo returning from these limbs to the thalamus inhibits th vasoconstrictor tone of the vasomotor centre and lead to dilatation of the peripheral vessels; blood-flow t the fingers, in a normal person, may thus be increase 100 times. Such treatment, however, has not bee successful in these thiopentone cases; nor has it in th intense digital spasm due to high-altitude frostbit Warming the body will sometimes not release the spas in some of the Raynaud's attacks following cold.

Elevation of Limb

The affected limb should be kept elevated to assi both venous and lymphatic flow. Such elevation shoul not, however, be above heart level, and the effect on pai should be observed. "The customer is right" is a soun rule: if the patient complains of excessive pain, th limb should be slightly lowered (Cohen 1946a). point often overlooked, and I have seen it in one of th thiopentone cases, is that, if the patient is permitted t sit up, the pillows must be adjusted to raise the ar to shoulder level (Barnes 1942).

The importance of promoting venous flow cannot b over-emphasised, for experience shows that, shoul venous clotting take place in the limb with sluggis circulation, the fate of the limb will be sealed (Cohe 1946b, Leriche 1945). Gentle finger exercises may b encouraged, but vigorous movement should not b permitted, for such exercise may precipitate the furthe

ACUTE TRANSVERSE MYELITIS COMPLICATING PNEUMONIA

REPORT OF A CASE

A. I. Suchett-Kaye
M.D. Paris
SSISTANT MEDICAL OFFICER, ST. CHARLES' HOSPITAL, L.C.C.

Myelitis, though common in many different infections, rarely a complication of pneumonia. Hassin and Broder[1] eported a case in which the patient died despite treatent with sulphonamides and penicillin, and necropsy owed bronchopneumonia of the right lower lobe and xtreme softening of a dorsal segment of the spinal cord. heppe et al.[2] recorded the history of a naval officer ho, during an attack of primary atypical pneumonia, eveloped an acute myelitis with paraplegia, paralysis f the intercostal muscles, and typical changes in the erebrospinal fluid (C.S.F.); he subsequently recovered ithout sequelæ.

The following case of pneumonia ended fatally because f the onset of a severe transverse myelitis.

A lorry driver, aged 40, was admitted to St. Charles' ospital on April 17, 1947, with seven days' history of spnœa, cough, hæmoptysis, and pain in the left side of e chest.

On admission his temperature was not raised, but his spirations and pulse were rapid. A cough producing pious sticky heavily bloodstained sputum was present. he percussion note was impaired at the left base, with minished air entry and moist crepitations. The abnormal ysical signs became more pronounced next day, and the tient's general condition deteriorated. He looked pale, n, and toxic; his tongue was dry and coated; and though s temperature was still normal his pulse-rate was 100–140 r min. All other systems appeared to be normal. No bercle bacilli were found on repeated examinations of the utum, but one specimen grew predominantly Pfeiffer's cillus. Pneumonic consolidation of the left lower lobe s diagnosed, and 'Sulphamezathine' was given in full ses. After three days the hæmoptysis stopped, and a est radiogram now showed enlargement of the left hilar mph-glands and patchy consolidation in the left lower lobe. blood-count soon after admission revealed a leucocytosis 23,000 white cells per c.mm. (polymorphs 81%, lymphotes 17%, eosinophils 1%, monocytes 1%). The urine was rmal.

On April 21 the patient complained of numbness and gling in both legs. He could not micturate voluntarily, d his bladder became much distended. Voluntary power s diminished in the legs, with patchy loss of all forms of nsation over the lower limbs and trunk. The tendonflexes were normal and the plantar response flexor on both des. Next day, for the first time since his admission, the patient's temperature rose to 101°F, while his pulse-rate remained at 120–140 per min. Blood-pressure 150/100 mm. Hg. An acute transverse myelitis was now obviously present: there was a complete flaccid paralysis with loss of all sensation up to the level of C6, with paralysis of the urinary and rectal sphincters and the intercostal and other respiratory muscles. Respiratory distress was pronounced and it w aggravated by the consolidation of lung.

On April 22 the C.S.F. was slightly turbid; pressure 200 mm. Hg; Queckenstedt test negative; contained 220 white cells per c.mm., with slightly more lymphocytes than polymorphs, and 150 red cells per c.mm.: globulin increased; total protein 320 mg. per 100 ml.; chlorides 680 mg. per 100 ml.; gram film showed pus cells but no organisms; no tubercle bacilli were found in Ziehl-Neelsen film; culture sterile; colloidal gold *test* 5554223210; Wassermann reaction negative.

In a few hours the patient's dyspnœa became alarming, with shallow and laboured respiration, cyanosis, and inability to expectorate. The sulphonamide treatment was supplemented with penicillin, and the patient was placed in a mechanical respirator. There were no signs of improvement however; his fever became hectic in type (99–104°F) and the consolidation spread to the whole left lung. Throughout the illness the spinal-cord lesion showed no change, the level of sensory loss remaining about constant. The patient's general condition occasionally improved temporarily, but the persistence of the paraplegia and pyrexia were of sombre prognosis. The C.S.F. unexpectedly became normal. On April 25 it was still slightly opalescent; pressure 150 mm. Hg; Queckenstedt test negative; white cells 82 per c.mm., lymphocytes greatly predominating; total protein 40 mg. per 100 ml.; globulin only a trace; chlorides 670 mg. per 100 ml.; no tubercle bacilli seen in stained film; cultures sterile. By April 30 it was clear and "water-white"; pressure 150 mm. Hg; 12 lymphocytes per c.mm.; total protein 20 mg. per 100 ml.; globulin not increased. Repeated blood-cultures were sterile; Wassermann reaction and Kahn test were negative; radiography of the cervical spine showed no abnormality.

The patient died on May 15, after remaining in Drinker's apparatus for 23 days, during which time he had two courses of sulphonamides (total 64 g.) and of penicillin (total 17,100,000 units).

Necropsy (Dr. C. E. Bryson).—Unresolved pneumonia of left lung involving both lobes; early abscess formation: right lung emphysematous and purulent bronchitis present. Bladder contained some turbid urine but there was no actual cystitis (a fact worth mentioning considering the number of times the bladder had to be catheterised during life). The mid-cervical cord (C4–D3) was œdematous and very soft, with disorganisation of the grey matter, consistent with an acute transverse myelitis: the central canal was dilated in one segment at the level of C7. Tissues of segments C5, C6, and D1 examined histologically confirmed the diagnosis of acute myelitis.

DISCUSSION

In this case an otherwise ordinary pneumonic consolidation in an afebrile patient, with signs of toxæmia. became complicated by a transverse myelitis affecting predominantly the cervical segments. From the beginning the patient, though relatively young, showed little natural resistance to the illness. The paralysis of respiratory muscles, necessitating the continuous use of the iron lung, was an important factor in aggravating the pneumonic process, and the patient finally died of asphyxia.

At no time did the injured spinal cord show any clinical evidence of recovery, though the acute inflammation, as judged by the C.S.F., may eventually have subsided. The severe hæmoptysis and paraplegia at first suggested tuberculosis, especially since the C.S.F. showed lymphocytic predominance with absence of organisms. It seems probable, however, that both the pneumonia and the myelitis were caused by the same virus. This would explain the initial consolidation without pyrexia, the absence of crisis and response to chemotherapy, and the failure to isolate a causative organism in the sputum.

I am indebted to Dr. A. J. H. Reford for his help in the management of the case.

Four previously published cases are reviewed; in three of these full operation details and some pathological material have enabled a closer study.

Experience gained from arteriography is used to shed light on factors such as pain on arterial puncture, vessel spasm after injection, and the height that injected fluid will ascend against the flowing arterial stream.

Phlebography indicates that there is considerable distal blood-flow in the forearm when an injection is given at elbow level; the effects and dangers of venous thrombosis are emphasised.

Arteriography and experiments confirm that, to explain the high thrombosis and skin lesions in some of the cases, there must have been temporary occlusion of arterial flow during the injection, either by inadequate release of the tourniquet or by posture of the patient on the operating-table. The mechanical factors likely to obstruct arterial flow at the cervical outlet are described.

Clinical features are discussed: the character of the pain; sloughing cutaneous patches due to thiopentone shunt into the cutaneous arteries; muscle death due to arterial thrombosis; œdema of forearm; nerve effects due to interference with the blood-supply of the main trunks; and late thrombosis.

The effects of thiopentone are held to be due to its high pH. Trapping of the solution in the arterial tree is regarded as momentary, for with small dosage used in some of the cases unconsciousness was only a little delayed.

Extensive thrombosis of the major vessel, and distal arteriolar spasm, are shown to be in the main responsible for the sequelæ. Other mechanisms are discussed.

The variable anatomy of the arterial tree at the elbow is described, and the less serious lesion, following injection into an aberrant ulnar vessel, is shown to be due to the arrangement of the divisions of the brachial artery.

The rationale of the management of these cases is described. Brachial-plexus block is advocated as part of the therapy, and posterior sympathetic block regarded as difficult and hazardous.

If operation has to continue, the most suitable anæsthetic as regards the peripheral vessels is cyclopropane.

Anticoagulant therapy (heparin), in large doses early, is advocated, with exposure and direct injection into the brachial artery, if the anæsthetist is sure of the accident.

Arteriotomy and extraction of clot are probably the operation of choice, the incision being made well above the injection site.

Arterectomy has no physiological sanction and is particularly dangerous if triple ligation is undertaken.

Late exploration is regarded as not worth while.

The local care of the limb is detailed.

Tragedies that have followed the intra-arterial injection of contrast media or therapeutic substances have been collected.

Intra-arterial thiopentone may be hazardous to life as well as to limb.

These cases are in need of intensive study, for they throw much light on the pathological events in the ischæmic limb.

The buffering of thiopentone to render it non-irritating seems within the ken of pharmacologists.

There is urgent need for further experimental work, using larger animals.

These tragedies carry bitter memories for most of the anæsthetists responsible. I have therefore thought it advisable to suppress their names and can merely acknowledge their courtesy and great help in making available to me all the details. To the surgeons who have given me the right to publish their operative findings, and even to criticise from the "touch-line," I can only offer similar anonymous expression of my gratitude; it was felt better for me not to indicate, by naming the surgeons, where such tragedies took place. Human nature, being what it is, is apt to blame and see t faults in others only too readily.

Prof. J. Dible has kindly given me his opinion on the ve sections. Prof. J. Kirk, of Middlesex Hospital, has acted most stimulating fashion as the "backroom boy," discus with me the variable anatomy of the arterial tree and mak available some of Quain's original masterpieces. It is pleasure to acknowledge the cheerful coöperative exp help of Mr. V. W. Willmott, A.R.P.S., of the British Po graduate Medical School, in preparing the photomicrograp and other photographs for me. I am much indebted Mr. J. Robson for the illustrations.

THE LANCET

LONDON: SATURDAY, SEPT. 11, 1948

Private Patients in Health Centres

GRATIFYING progress has been made towards the tablishment of an experimental health centre at echford, Birmingham (see p. 428). The local health thority has secured a site, and has prepared plans hich have been approved by the local executive uncil. The local medical committee has promised give the project its full support The doctors ractising in the neighbourhood have discussed the heme. and enough of them to give the experiment ery chance of success would be willing to practise om the centre if terms and conditions of service ere satisfactory. The plans have gone forward to e Ministry for sanction and some first inquiries ave been made as to the conditions of service in e centre when established. Unfortunately, as we oted last week (p. 399), the answer to one of these iquiries threatens to jeopardise all further progress. he Minister, basing his answer on the strict interpre- ation of section 21 (1) (*a*) of the Act, which says at it shall be the duty of the local health authority provide health centres at which facilities shall be ailable "for the provision of general medical rvices under Part IV of this Act by medical prac- itioners," has decided that doctors could not be rmitted to treat private patients at health centres. he local doctors feel they could not take service in he centre if this were among the required conditions. heir objection has been sympathetically received by he local executive council, which has unanimously pproved a report by its general purposes committee eclaring that adherence to this ruling would be etrimental to the health service.

The doctors can bring forward strong arguments on heir side They do not wish it to be believed that hey are offering two standards of service—one for H.S. patients in the health centre; the other omething different. and perhaps better for private atients in their own surgeries. They cannot use their time to their patients' best advantage if they have to duplicate every consulting-hour and be available for one set of times each day at one address and for another elsewhere. Moreover. in these days of domestic difficulties, not least among the vaunted attractions of the health centre was the new feeedom it was said to offer to the doctor's household and particularly to his overworked wife. This is largely lost if consulting-rooms must still be retained, cleaned, and serviced in the doctor's private house while he also attends the centre. If, too, the centre offers, as it should do, a better standard of practice with greater opportunities for mutual help between the doctors practising there, must the patient who has elected to remain a private patient of his own doctor be denied the advantages which the centre offers —always remembering that he, as a rate-payer, is helping to provide them? Lastly, if the doctor is to be required still to maintain private professional premises even though he agrees to work from a health centre, and to pay rent for his accommodation there, he will be facing an extra financial burden which he may find hard to bear. He may regretfully have to refuse the offer of health-centre practice, or the rent for his facilities there may have to be materially reduced below an economic level to allow him to afford the two establishments, in which case the State would in effect, by accepting such token payment for rent in the health centre, be paying a subsidy to help the doctor to provide a separate service at his own surgery for his private patients. This surely is no more defensible than the alternative of allowing the use of the centre for purposes not specifically defined in the Act.

There are theoretical considerations which at first sight might be thought to justify strict adherence to the words of the Act. Undesirable as it is to foster two standards of practice, one inside and the other outside the health centre, even this might be preferable to the risk of encouraging two standards of service, or at least of amenity, inside the health centre. Private patients, it could be argued, if allowed to see their doctors in the centre, would expect prior or better attention than that afforded to patients enrolled under the health service. But need they be given such extra privileges? In the past many doctors have conducted their practices satisfactorily without making distinction in their surgeries or their waiting-rooms between private and panel patients. If in the health centre each doctor is allowed his own suite with its individual waiting-room, he should not find it impossible to continue to give a service satisfactory to both groups of patients, without either group being put at a disadvantage by the other. It might also be objected that problems of administration and remuneration might arise if much private practice was carried out at the centre. The centres will be built and maintained by the local health authority, who will also employ and pay the lay staff. The doctors will use the premises and share the services of the staff. For this they will each pay an agreed charge —probably by a deduction from their remuneration. So long as the doctor's use of the centre is confined to the fulfillment of his duties under part IV of the Act, his share of the expenses is relatively easy to assess, and it could be made to vary directly with the number of patients for whom he has contracted to care. If he is allowed private practice from the centre, it will be very difficult to estimate the demands his practice is likely to make on the centre and its staff; and the calculation of a fair division of expense between the different doctors may well be impossible. But need this trouble the authorities if the doctors can themselves find a way of sharing satisfactorily among themselves, by some partnership or other binding agreement, the over-all charges which are payable for their use of the centre? No greater departure in principle would be needed than has already been made by allowing private practice from State-provided hospitals for the consultant. In fact the same main argument holds good. Mr. BEVAN has defended his action in allowing this privilege to the consultant on the plea that he wished to keep the consultant working inside the service and not having to spend an undue time elsewhere; and that he wished the patient to feel that he could get the best service possible inside premises provided by the National

Reviews of Books

British Surgical Practice

Vol. III. Editors: Sir ERNEST ROCK CARLING, F.R.C.S., F.R.C.P., consulting surgeon, Westminster Hospital; J. PATERSON ROSS, M.S., F.R.C.S., director of surgical clinical unit, St. Bartholomew's Hospital, and professor of surgery in the University of London. London: Butterworth. 1948. Pp. 561. 60s.

WE have already reviewed the first two volumes of *British Surgical Practice*.[1] Volume III is no disappointment. It contains 63 sections, beginning with "Cæsarean Section" and closing, appropriately, with the "Eyelids." The ear, the eye, and endoscopy account between them for 28 sections. Some of the articles are better than others, but there is not a bad article in the book. The uniform lucidity of contributions by more than 50 authors is a great tribute to the editors, and the illustrations are numerous and good. It is clear, as the successive volumes emerge, that this work is achieving the very difficult and ambitious task which it set out to accomplish—to present an up-to-date and authoritative survey of British surgery.

Diagnostic Procedures in Virus and Rickettsial Diseases

Editor: T. FRANCIS, jun. New York: American Public Health Association. 1948. Pp. 352. $4.

To diagnose most of the virus diseases described in this book, inoculation of animals is needed on a scale practicable in this country only in the better equipped research institutes. To diagnose others, however, much may be done by the use of fertile eggs and by various in-vitro tests. The authors of the chapters in this book are all experts and describe in great detail methods of working with their own special viruses—methods which will often not be possible except to specialists. The transmission of mumps to monkeys, or of sand-fly fever to human volunteers, for instance, are never likely to be counted regular "diagnostic procedures." The precautions necessary to avoid infecting laboratory staff are described, and some instructions are offered on the proper care of laboratory animals. The account of psittacosis by Meyer and Eddie is particularly good. That by Rake on lymphogranuloma venereum inflicts on us an unaccustomed binomial nomenclature: we are asked to call the virus *Miyagawanella lymphogranulomatosis* (it seems unlikely that many of us will). Parker's chapter on variola and vaccinia is less full than most, and does not mention hæmagglutination. That by Feller on primary atypical pneumonia tells much about cold agglutinins and agglutination of the MG streptococcus—both far from being pathognomonic tests—but little about the virus described by Eaton and his colleagues. But most chapters—on mumps, poliomyelitis, encephalitis, herpes simplex, and so on—are very good. The writers are highly individual, and there is some overlapping and perhaps even a little contradiction in the accounts by different authors of similar techniques; but the book is a valuable reference work for those engaged in research and in public health.

Calcium and Phosphorus in Foods and Nutrition

HENRY C. SHERMAN, Mitchell professor emeritus of chemistry, Columbia University. New York: Columbia University Press. London: Oxford University Press. 1947. Pp. 176. 15s.

MUCH work has been done on calcium and phosphorus metabolism since Professor Sherman wrote the first edition of his *Chemistry of Food and Nutrition*; and few have so good a claim to bring the subject up to date in a book with a fairly general appeal. He begins by explaining why there is a nutritional problem connected with calcium and phosphorus: the animal is born with so little and needs so much that food which is otherwise satisfactory may fail to meet the body's requirements. There follows a general account of the calcium in the body, its combined forms, and its functions in the bones and tissues, which leads to an excellent study of the effects of food and growth on the body's calcium content. He deals well with the vexed question of calcium and phosphorus requirements and the problems of and optimal intakes, but is not so happy when discuss why some foods supply calcium more readily than oth

Professor Sherman is at his best when dealing w the relationship between intake and retention, point out that passably normal health can be maintained— a lifetime and even through successive generations— very different levels of calcium intake and outp and on somewhat different concentrations of calci within the body. He then marshals evidence to show t a high intake of calcium is always beneficial, even elderly people, and that 1 g. a day is a good all ro figure, with rather more for adolescents and for pre and nursing women. In his view, an excess, w reason, has no pathological consequences, but not eve body who believes this has the courage to say so, many will recall from the controversy that arose h over the addition of calcium to flour.

There are a few weak points in the book; Profes Sherman implies that phosphorus deficiencies are uncommon in infancy, which seems improbable, and ideas about rickets may be applicable to the rat but scarcely be accepted as applying to man. There ar few serious mistakes (adenine is numbered among pyrimidines rather than the purines) and some omissi which workers in this country will find difficult to exc Thus the rôle of phytic acid in calcium metabolism its importance in cereal diets are not discussed, thou quite a lot is said about the oxalic acid in spinach and effect in making the calcium in this vegetable relati unavailable. Some reference to the fundamental w of the Mellanbys seems essential in a work of this ki but this and the pioneer work of Miss Harriette Chi on osteoporosis in middle-aged people are omitted. these defects were corrected the book would be o of the most valuable introductory monographs nutritional science.

About Cosmic Rays (London: Sigma Books. 1 Pp. 144. 8s. 6d.).—In this volume of the Sigma Introduct to Science series Mr. John G. Wilson, PH.D., gives a clear a concise account of the discovery of cosmic rays, and the fac established and theories elaborated about them. The Ge counter and the cloud chamber, and the ways of using the are fully described and illustrated. This book can be thoroug recommended to those interested in atomic physics.

Hernia (3rd ed. London: H. Kimpton. 1 Pp. 700. 67s. 6d.).—Surgical books are of three typ there are textbooks giving orthodox teaching, monog recording the views and experience of an author, encyclopædias which profess to cover the whole of a sub but should nevertheless make some attempt to separate chaff from the wheat. This book by Dr. Leigh F. Watson, Los Angeles, sets out to be an encyclopædia of hernia surge and it contains as much as the industrious author can between two covers. "Nature's method of preventing t protrusion of viscera into a preformed sac consists of provi ing an oblique canal"; "in inguinal hernia the portion of t sac lying within the inguinal canal is called the neck"; "acute coronary thrombosis is sometimes mistaken for a sm occult strangulated hernia"; "in infants the obliquity of t inguinal canal is slight, because it passes almost direct through the abdominal wall"; "direct inguinal hernia infrequent"; "new growths in undescended testes rare"; "in Great Britain the simple ligature of the s operation in young infants is usually performed in the O Patient Department": such statements abound. Dr. Wats seems hazy about the ætiology of indirect inguinal hern At one time he says "it is generally believed that all indire hernias are due to a preformed sac," at another, "in indire inguinal hernia the sac first bulges at the internal ring . . . removal of the tension the peritoneum quickly resumes normal shape . . . on continued repetition of the strain t ring gradually relaxes . . . the peritoneal pouch finally ceas to return into the abdominal cavity." On p. 130 the pr formed-sac theory is given, while on p. 131 the balloon theo is illustrated in all its crudity.

The account of operations is slightly better, but is marre by lack of discrimination, and by a passion both for the ne and bizarre, and for the old and quaint. Murphy's button advocated, and even Moynihan's bone bobbin, that wen out of use in 1906. Dr. Watson himself seems to like injectin hernias; he may be right.

---

[1] *Lancet*, 1947, ii, 912 and 1948, i, 678.

e all characteristic of human nutritional anæmia it not of pernicious anæmia. Indeed, CARTWRIGHT' id his associates were surprised that their liver tract (which contained no significant amount of lic acid) produced any response at all, because the et contained adequate extrinsic factor and pig's omach is one of the richest sources of hæmapoietin. A similar anæmia has been artificially produced in ts by Dr. WATSON and his colleagues in Prof. L. J. ITTS's department at Oxford. Their technique, hich they describe on p. 404, was to fashion an testinal short-circuit and leave a blind loop; the perative mortality was lowest with a 3-in. loop at filled with peristalsis. The bone-marrow in their nimals also contained abnormal erythroblasts resembling megaloblasts. This rat anæmia, too, resembled a utritional rather than a pernicious anæmia, and in the bsence of infection large doses of a purified liver extract roduced a remission; a single injection of folic acid as tried in one rat which had responded only partially o liver extract, and its hæmoglobin and red-cell ount rose to nearly normal.

Here then are experimental techniques that should t least enable us to find out how folic acid acts in egaloblastic anæmias. There seems little doubt that he odd erythroblasts found in the animals' bonenarrow are of megaloblastic type and are not hyperlastic normoblasts since we know that the latter are ot affected by folic acid. The results suggest that here are several ways of producing megaloblastic hange in the marrow; it may be—as WELCH [4] has uggested—that folic acid and the anti-perniciousnæmia liver principle bring about superficially imilar results by different paths. The discovery of itamin B_{12} may mean that there are several subtances that can restore megaloblastic marrow to ormoblastic. But it is tantalising that when the xperimental megaloblastic anæmia—so long striven or by so many workers—has in fact been produced, it is still not of a type that can be used for the standardisation and assessment of liver extracts for the reatment of pernicious anæmia.

International Industrial Medicine

NEXT week more than 700 delegates from 46 nations will attend the Ninth International Congress on Industrial Medicine at the Caxton Hall, London. It is sponsored by the Commission Internationale Permanente pour la Médecine du Travail, which was founded in 1906 as a private society of industrial physicians by LUIGI DEVOTO of Milan; and it is a fitting tribute to BERNARDINO RAMMAZINI, one of the greatest of industrial physicians, that his fellow-countryman should have inspired this international society more than 200 years after his death. The commission now has a permanent committee in each country where industrial medicine is being practised on a large scale. The British committee are the hosts for this congress, the first to be held in Great Britain. The work of the Commission Internationale has often been wrongly associated with that of the International Labour Office, which is officially sponsored by governments, employers, and trade-union organisations in the New and Old Worlds The I.L.O. probably has made the greater contribution to international industrial medicine by adopting codes of health, safety, and welfare in industry, which it has supported by collecting and disseminating information of international interest. These two bodies exemplify in different ways the efforts made officially and privately to overcome the difficulties of travel and strange tongues and to break down the national frontiers of medicine. Prof. L. CAROZZI, the commission's secretary-general in Geneva, has held together this international fellowship in spite of the long years of war and shortage of funds.

Since the last congress,[1] held in Frankfurt in 1938, there has been a fundamental change in the subjects for discussion, from a limited academic approach to one which not only covers a much wider academic field but is essentially realistic. In 1938 there were 3 sections: occupational diseases, industrial accidents, and a combined section which dealt mainly with predisposition to industrial-disease and disability. In the forthcoming congress there are 6: social aspects, occupational environment, medicine and toxicology, nursing, industrial medical practice, and a special section with sessions on the medical content of law and the application of legislation. The congress of 1948 clearly means business. It will discuss the training of industrial medical officers and nurses, and the organisation of industrial medical services. Methods of controlling industrial health hazards are now well established, but they need to be refined and modified so that they may be applied as widely as possible, particularly to the small workplaces which now have little or no continuous health supervision. This is a problem of organisation which might well be raised in the congress discussions. All industrialised countries must face it, for the small workplace is still the backbone of world industry. Industrial accidents as a cause of disability still outweigh occupational disease in importance. High standards of safety engineering alone can never successfully control the human factors responsible for most accidents. Yet the original work by GREENWOOD and WOODS [2] and by FARMER and CHAMBERS [3] on accident-proneness has had very limited applications. Industry and Government must still support fundamental research and not rely too much on established methods.

In the first place medicine served industry by helping to control disease and treating industrial injuries, and these services are still important today, particularly where the risks of accident and industrial disease undermine the health and morale of a particular group, such as coalminers on whose output European recovery largely depends. But the changed concept of industrial medicine's rôle is well illustrated in next week's programme. It includes socio-medical and psychological problems of incentives, work, and skill Wisely the organisers have included contributions from psychologists and sociologists; for health and efficiency in industry are no longer the prerogatives of doctors, who have welcomed these scientists as colleagues in the battle to raise production. If medicine in industry is to survive and grow there must be radical changes in the training of students and industrial medical officers. So long as

Health Service. Surely the aim should be to give the doctors and their patients, whether health-service or private, the best facilities in general as in specialist practice—and this must mean giving them all access to health centres.

What is needed now is the early establishment and trial of some experimental health centres. The emphasis must be on experiment. No more than a few trial centres are at present feasible. Experiment should be not only in shape, site, or building materials but in ways of running the centre and of ensuring successful cooperation between the patient, the doctor, the lay staff, and the health authority. Can we not as part of our experiment try out the effect of having private patients attending health centres? The risk of their swamping the centre and making undue demands on it is minute. The very small proportion of the community who have elected to remain private patients have mostly done so to avoid *having to come to see the doctor: they think it worth* paying their fees so that they can still ask him to call for their own convenience. If the experiment *showed that private practice in the centre was* incompatible with the successful conduct of the centre's other functions, this sanction could be withdrawn before wider health-centre provision was embarked upon. If, on the other hand, the plan was found to work happily, then one of the major obstacles to coöperation by the doctors would have been removed. What is important now is that the Birmingham experiment, which looked so promising and which could still provide a valuable testing ground for our theories, should not be stillborn because of failure to secure agreement over this one point of controversy.

Experimental Megaloblastic Anæmias

THE discovery that folic (pteroylglutamic) acid will cause human megaloblastic *anæmia to remit and* transform the pathological megaloblastic marrow to a normoblastic state has not, so far, simplified our *understanding of the pernicious group of anæmias.* On the contrary, a host of new problems has appeared. The evidence makes it clear that neither folic acid nor its naturally occurring conjugate (pteroylheptaglutamic acid) is CASTLE's extrinsic or intrinsic factor —WILKINSON's hæmopoietin. Folic acid relieves the anæmia of sprue, but the failure of fat absorption remains; it will produce a normal blood picture in pernicious anæmia but leaves the neurological part of the syndrome unaffected or worse. Various theories to account for the action of folic acid have been suggested, but they are difficult to test in human disease. It is not therefore surprising that renewed attempts have been made to induce *suitable* experimental anæmias in animals. These experiments have been helped by the discovery of a folic-acid antagonist in the *form* of a methylfolic acid.[1] When this antagonist is given to rats the resulting changes in the blood and blood-forming tissues are similar to those produced by a purified diet with succinyl sulphathiazole to prevent bacterial synthesis of folic acid in the intestine. Neutropenia, and not anæmia, is the prominent part of the rat syndrome, so other animals have been tried. The pig has long been
regarded as peculiarly suitable for experiments
at reproducing human anæmias. WELCH, HEINLE
and co-workers[2] fed three pigs on a purified
free from CASTLE's extrinsic factor but containing
cinyl sulphathiazole and folic-acid antagonist. T
claimed that the animals developed a macroc
anæmia with curious changes in the bone-ma
resembling the megaloblastic change seen in hu
disease. One of their pigs responded promptl
intramuscular injections of folic acid, one to a mix
of folic acid, liver extract, and nicotinamide, and
to liver extract alone. This was a surprise
chicks, rats, and monkeys with folic-acid defici
do not respond to liver extracts.

These pig experiments have been repeated u
somewhat different conditions by CARTWRIGHT
others.[3] They fed four pigs on a diet low in pro
but containing adequate extrinsic factor; they
folic-acid antagonist and succinyl sulphathiazol
before, *and they also took the precaution* of preve
their pigs from getting any folic acid for 3–4½ mo
before the experiments began. The diet did not con
any folic acid, p-aminobenzoic acid, or inositol. F
other pigs received the same diet plus these mis
factors and were not given folic-acid antagonis
succinyl sulphathiazole. This group served a
control and they showed no changes apart from
retardation of growth because of the low pro
content of the diet. The four pigs did not appre
their régime. They became weak and listless,
appetite fell off, their coats lost shine, their abdo
sagged, and their squeals became faint and w
They had diarrhœa, and growth was poor. In
weeks the animals developed an anæmia which sl
became macrocytic, and the granular leucocyte
the blood diminished. But the most striking cha
were in the bone-marrow; here the erythrob
were increased and the granulocytes proportion
reduced; in addition to the normoblasts
appeared 11–22% of abnormal erythroblasts cl
resembling the megaloblasts seen in human perni
anæmia. *These megaloblast-like cells had* not
seen in the marrow of animals rendered anæmi
bleeding, nor did they occur in the marrow of
control pigs. When a purified liver extract in relati
large doses was given to these pigs the resp
varied: one pig showed no change at all, where
two others there was a partial remission of the ana
but the bone-marrow still contained megalobl
Folic acid, on the other hand, produced a ty
reticulocyte response with remission of the anæ
and megaloblasts disappeared from the bone-mar

The importance of these American experimen
that for the first time an experimental megalobl
anæmia has been produced—a result attempted
not attained by various methods of resectio
stomach and intestine in pigs. This experime
anæmia syndrome resembles human sprue or tro
macrocytic anæmia rather than pernicious anæ
—the signs of nutritional failure, diarrhœa, pa
conversion of the marrow to a megaloblastic state,
partial response to large doses of purified liver ext

r a verdict. but the sceptically minded will run h the "results" without much conviction.

practical usefulness of any system of statistical : cannot be too frequently or too insistently)ned. We live in an age when the urge towards llection of statistical data can easily run riot. here is danger that time and trouble may be it fully justified if it produces data not previously ole, irrespective of their practical usefulness. It be a great help therefore if we could have from mmittee responsible for this latest and admittedly urvey a direct and positive statement of the con- is they draw. Do they, in the light of their local edge, feel that the results they have set down sufficient practical importance to warrant further ment along these lines? Is this analysis of an g hospital service really a help in deciding what to be, or will be, provided *tomorrow*? The ation of the survey unaccompanied by the com- 's own verdict may lead others to follow suit it a clear perception of the ends likely to be ed.

POISONOUS BERRIES

IOST every summer brings its crop of accidents, imes fatal, through the consumption of poisonous s, often mistaken for blackberries. This summer exception. The account, on page 438, of two nts of this sort in the south of England is, how- notable for the survival of the children who con- l the berries of the Deadly Nightshade, while the who ate those of the usually less poisonous Woody shade died.

the nightshades belong to the family solanaceæ are more or less poisonous, except Enchanter's shade (*Circæa lutetiana*), which belongs to a ent order and is not poisonous. Two genera of olanaceæ are found as weeds in England—atropa solanum. *Atropa belladonna* is considerably rarer the several species of solanum and thus provides cases of poisoning; this is fortunate because all arts, especially the berries, are poisonous and it up to its popular name of Deadly Nightshade. solanum weeds include *S. dulcamara*, the com- st, and *S. nigrum*, whose folk-names are somewhat dled; *S. nigrum* is called Common Nightshade, k Nightshade, Woody Nightshade, and Bittersweet, last two names being shared with *S. dulcamara*. ivated species include *S. tuberosum* (potato), and *copersicum* (tomato). The poison has been found in pe potatoes and in the young shoots, leaves, and stems ie plants. Another cultivated solanum, the Wonder- y, something like a large bilberry, was discarded after its introduction some thirty or forty years ago, ugh fear of possible poisoning. For the same reason iatoes were long cultivated as ornaments, under name of Love Apples, before they were eventually epted as food.

he active poison of Deadly Nightshade is atropine, that of Woody Nightshade and Black Nightshade mine. Deadly Nightshade may be distinguished by corolla, which is bell-shaped, whereas those of the num nightshades resemble the potato plant's. The ies of Deadly Nightshade are black, shiny, and about arge as a cherry. Bittersweet (*S. dulcamara*) has a dy stem, alternate cordate leaves, and red oval ies ½ in. long, and it straggles over other plants in ges and thickets. Its drooping clusters of flowers are ie on a stem which usually arises opposite a leaf. petals are either white or lilac-blue with a green spot he base of each surrounding a yellow cone of anthers; poison is chiefly concentrated in the berries. The d stems are official in the *British Pharmaceutical* x. There is a maritime variety with a prostrate stem. lack Nightshade (*S. nigrum*) has white flowers and k globular berries, which are also poisonous, about the size of haws. Its stem is not woody and its leaves are ovate. Varieties with red and with yellow berries are known, such as the Jersey variety with dentate leaves and scarlet berries.

When it is suspected that a child has swallowed the berries of one of the solanum family, what should be done? For practical purposes all solanum berries are poisonous. The immediate necessity is to empty the stomach as effectively as possible; remembering that whole berries or large fragments of them will usually not pass through a stomach-tube. Thereafter the child should be kept under close medical supervision, preferably in hospital.

AN EAGLE IN THE DOVECOTES

"THERE is no force so great as that of an idea whose hour has struck," Mrs. Margaret Sanger quoted, at the congress on *Population and World Resources* reported in these columns last week. She might have added that the force of an idea derives from human personalities—sometimes, it almost seems, from one personality. She was recalling the history of family planning in America, of which she has been the pioneer. In Great Britain we have been fortunate in that family limitation has never been regarded as a crime. Things were different in America thirty years ago, when Margaret Sanger is reported to have "appeared on the horizon with three children in her arms and a wild look in her eye." She had been working among the poor in New York, and had been dismayed at the unnecessary burden and suffering borne by women, and dreaded by them for their daughters, in slums where pregnancy followed pregnancy and poverty deepened with each child. She was ready to challenge the Comstock laws which for thirty-five years had blighted free discussion of human relations and sexual ethics. Anthony Comstock, she said, had ideas about purity and was determined to enforce them. Abortion, even on therapeutic grounds, the practice of contraception, and the sale of contraceptives or of publications about contraception were punishable by long imprisonment and heavy fines. Since it was illegal to send any printed matter about contraception through the post, a large government staff was kept busy opening other people's letters and parcels. An editor of 70 was sent to the penitentiary for starting a journal—"Dr. Blacker please note"—called the *Eugenics Review*. The same fate befell the editor of a free-thought weekly, because he challenged Comstock. Margaret Sanger was indicted for publishing a little monthly insisting on the right of women to space their families. She was determined to tell them how to do it, too, but a hunt through the libraries for information produced only a small book pointing out how wonderful it was to have children.

Conditions in a city which prided itself on its municipally owned apartment houses were a cynical comment on this find: the apartments were built to take parents with no more than four children; if they exceeded the ration they were asked to move, and by the time they had seven or eight they were living down in the shipyard slums. Margaret Sanger's trial was postponed, and she seized the moment to write a pamphlet on family limitation, which was printed and packed up for mailing before she sailed for Europe to prepare her defence. When she was well in the middle of the Atlantic the pamphlets were posted, the recipients including the judge, the district attorney, the President, and Mr. Anthony Comstock. In England she was welcomed by a group of warm admirers, Havelock Ellis, H. G. Wells, Edward Carpenter, Gilbert Murray, the Drysdales, and Dean Inge among them. By the time she returned for her trial feeling in the United States was so strongly in her favour that the case was dropped. "I am sure Mrs. Sanger won't do this again," said the district attorney. "I assure you I shall," she replied, and soon afterwards opened, in New York, the first practical birth-control medical students are taught about the rare diseases rather than about sick human beings who have to work, their interests in occupational medicine, both as general practitioners and doctors in industry, will be confined to the treatment of industrial injuries and the investigation of industrial disease. They must be interested in the material and psychological factors which affect the health and efficiency of every working community, not only those inside factory gates and down mines. On their own doorstep the medical profession have the urgent problem of attending to the health and welfare of nurses, the shortage of whom reflects the sad neglect of attention to their working conditions in hospitals. With such an extensive programme there is some danger of these sessions remaining uncoördinated and sealed in water-tight compartments. Improved health and efficiency at work depends on the combined efforts of doctors, engineers, physicists, chemists, psychologists, and industrial nurses. Every effort should be made to integrate these disciplines as far as possible. This can be done to some extent by unofficial discussions, it is perhaps unfortunate that there is no final session to bring the different experts together in discussion.

In this country, growing social security and great demands for production have happily r the evils of want and starvation, but at the time that most powerful of incentives—work want—has lost its force. Industry must find incentives. "Why men work" is a question w can never be easily answered. Experiment research, however, have shown that the human r tions of working groups, be they industrial, c mercial, or educational, have profound effects on urge to work. Speakers on incentives have the congress lists for the first time, and it is to hoped that this congress will stimulate further into human relations and will initiate practical ments in managing human beings in industry. this sphere more than any other the combined of the medical and social sciences can contribute to the *promotion of health and increased production*

HOSPITAL-TREATED SICKNESS

STIRLINGSHIRE has been submitted to the punch-card operation. The Glasgow Health and Sickness Bureau which, like its sister in Oxford, works under the auspices of the Nuffield Provincial Hospitals Trust, has prepared a special card in respect of each Stirlingshire patient treated in the year ended Sept. 30, 1947, at a hospital, whether inside or outside the county, and whether inpatient or outpatient. The object was to obtain "a complete picture of all types of hospital-treated sickness occurring among the known population of a given area," and Stirlingshire was chosen as fairly representative of the urban industrial belt of central Scotland. The committee responsible for the study had Prof. Thomas Ferguson as chairman, and nearly all its members were medical men. The report[1] briefly describes the methods used, and sets forth the results, analysed from various angles. The tables show the total volume of sickness treated in hospital (one in every seven of the population received hospital care in the year), the type of sickness and duration of stay in hospital, the geographical factors in hospital treatment, an analysis by age and sex of patients, and so on. There are also supplementary notes on various disease groups, indicating the incidence of diseases per 1000 of the population. The bureau is now engaged on a similar inquiry in the larger and more populous county of Ayrshire. It is suggested that the experience of the Oxford and Glasgow bureaux may be helpful when, as is presumably intended, the regional hospital boards come to build up machinery for keeping and analysing hospital records on standard lines. When this has been achieved "the community should have available reasonably sound guidance about basal hospital facilities that should be provided."

The appearance of this survey offers an opportunity to consider a very wide question. What kind of hospital statistics would really justify the considerable labour involved in their compilation? The Ministry of Health, wisely, has not as yet given any indication of the type of statistical material likely to be required. Miss Nightingale, on her return from the Crimea, was painfully impressed by the lack of scientific coordination in the statistics prepared by the various London hospitals, and for a while she bent her energies towards the introduction of model statistical forms. The general adoption of her forms, she wrote, would "enable us to ascertain the relative mortality in different hospitals, as well of different diseases and injuries at the same and different ages, the relative frequency of different di and injuries among the classes which enter hospital different countries and in different districts in the countries." Her scheme failed—the difficulty costliness of compilation, and the doubt about the v of the conclusions deduced from such figures as then published, were no doubt responsible for a gradual loss of interest on the part of the hospitals. Are we much further forward today than in the 1860's? The statistical returns required by King Edward's Hosp Fund for the last fifty years and adopted by many the hospitals in other parts of the country have afford much useful financial data, and have been a mine information on numbers of patients treated, duration stay, and so forth. But these returns have stopped short of Miss Nightingale's ideals, and the classificat of diseases has lain outside their scope.

It is claimed for the Stirlingshire survey that it shou be of service, "as a basic record of hospital faciliti actually available and used, in shaping an approach t broad administrative problems of hospital policy, by throwing into relief the general pattern of hospital-treate sickness and suggesting lines of medical and administra tive research." It is fair then to ask whether the pilo survey did justify the collection of further data o similar lines. Does the use of a simple card transcribe from the hospital records and fed to the new mechanica sorting devices offer informative results? Do thes results go beyond what can be deduced by simple means, such as those used in the hospital surveys The latter depended on data of the usual kind regardin the existing hospital facilities, the number of bed available, the occupancy and so on, supplemented by visits to many of the hospitals and a broad assessmen of needs based on verbal information as to the pressur on particular categories of accommodation. The waiting list is a notoriously unreliable guide, but indications o pressure in one direction or another, such as can b obtained direct from the hospitals, is a very relevan factor. The Stirlingshire survey is based on the assump tion that the new mechanical methods can offer dat not hitherto available to those who have to plan th hospital services of the future. Without a detailed knowledge of local conditions it would be presumptuou

COMPENSATION FOR INJURY *

H. C. Wardleworth Nuttall
F.R.C.S., D.P.H.
ULTING SURGEON, ROYAL LIVERPOOL UNITED HOSPITAL

HE present system of dealing with claims for com- sation for injury is unsatisfactory, and the National rance (Industrial Injuries) Act, 1946, will perpetuate e of its weakest features.

nder the present system an injured workman, after rting the accident to a representative of his employer, sults his panel doctor, who furnishes him with a ificate on which weekly compensation is paid. If e is any dispute the workman consults a solicitor, formulates a claim. In the event of the employer's sting the claim the case goes to arbitration, with the luction of opposing medical evidence and occasionally assistance of a medical referee. Common-law cases w a more or less similar course, save that they are in the High Court, and it is a question of damages er than compensation.

orkmen's claims under the new Act will be dealt by an industrial pensions officer. They must be mpanied by a medical certificate, and the applicant have to submit to examination by an appointed ical officer. The decision of the pensions officer be subject to appeal to a local appeal tribunal of loyers and workmen, with two coöpted medical titioners when necessary. The medical assessment pension will be made by a medical board, probably medical board of the Ministry of Pensions. There be a right of appeal against a final assessment to ibunal consisting of a chairman of a local appeal unal, and two medical practitioners. There is no p-sum compensation under the new plan.

THE CLAIMANT

he great majority of British working men and women, g normal healthy people, remain on the compensation s short a time as possible. They would feel ashamed ake a penny under false pretences, and are only anxious to continue working if possible. There however, many circumstances which may influence normal people to persist in a claim after they recovered, and there is always a proportion of rmal people among the injured. For instance, Workmen's Compensation Act makes no allowance a man's running into debt, and this is inevitable if incapacity lasts at all long. He is then faced with ars of payment to tradesmen which it would take rs to pay off out of his normal wages; and, unless ump sum is forthcoming, he feels that his only chance o persist with some complaint or other till he gets ress. During and since the war many people, parti- rly married women, have been forced into occupa- s which they dislike and naturally welcome a chance vading. Many other cases are probably psycho- hic misfits, self-centred, lazy, and mutinous, who lag nd or lack the skill to compete on even terms with r fellows.

THE DOCTOR AND DIAGNOSIS

he first doctor consulted by the claimant is of funda- tal importance, and often it rests with him whether e is a claim or not; and, if there is, whether it is l or not. Even today many doctors in the poorest ricts are not sufficiently independent and are con- isly or unconsciously influenced in giving certificates. he diagnosis in many cases of injury may be simple, prognosis is always difficult and may be impossible without specialist training. It is, however, on the prognosis that the case may be fought. Moreover, even the simplest case may be complicated by exaggeration or malingering. The doctor can scarcely be blamed for playing safe in cases of doubt. His remedy is to get a second opinion when the doubt warrants it.

It is most important to obtain a correct history of any accident. In most instances the type and degree of violence are directly related to the effects and could be predicted, or conversely the violence could be assessed from the effects produced. For example, many types of fracture, such as the fracture-dislocations of the ankle, are now known to be related to particular strains or types of violence. The converse is not so well established, and it is always of great value to elicit as far as possible the direction and degree of any force acting in any particular case, and to observe whether the description tallies with the alleged effects or not.

Case 1.—A man reported that he had fallen aboard ship and injured his right shoulder two months earlier; he had been radiographed at a cottage hospital and told that there was a fracture of the upper end of the humerus. He had been transferred to another local hospital, where radiography had been alleged to show fracture of the glenoid also. The patient had provided himself with copies of the radiological reports.

Careful and critical elucidation of the history of the accident revealed that he had fallen flat on his back. Examination showed extraordinary development of the muscles of both shoulders, more particularly those muscles concerned in movements of the shoulder blades, and that this abnormal development was equal; there was no wasting on the injured side; movements of the injured shoulder were free but not carried out at the true shoulder-joint but by means of an extraordinary or abnormal movement of the shoulder blade, so that in full abduction of the arm the lower angle of the bone projected two or three inches beneath the skin. In other words there was complete fixation of the true shoulder-joint. This conceivably could have followed a fracture of the upper end of the humerus with or without the glenoid, but the unusual development of the muscles and the wide range of movement had obviously been gradually developing for a much longer time than two months. Routine examination of the other shoulder disclosed complete fixation of the shoulder-joint with a full range of movement by means of abnormal shoulder-blade movements.

This strongly suggested that there was some identical cause for the similar condition in both shoulders and threw strong doubt on the probability of any accident. Radiography of both shoulder regions showed that the upper ends of both humeri and the glenoid cavities of each scapula were greatly deformed. The upper ends of the humeri were reduced to mere points, and the heads of the bones had run down the shafts like melted wax. A similar appearance was seen in the glenoids, and it was diagnosed as a type of melorheostosis of Leri. There was no sign of fracture or injury.

Errors in diagnosis were made in this case by not eliciting a correct history, and by neglecting to follow the routine principle of comparing one limb with the other.

A much more serious result of wrong diagnosis in the initial stages is delay caused by neglect or by incorrect treatment, as in the following case:

Case 2.—A workman fell and sustained a fracture-dislocation of his shoulder.[1] The dislocation was missed on radiography at the cottage hospital. The arm was bandaged, and later the patient was referred to an orthopædic surgeon, who discovered the dislocation by radiography but too late to reduce it. At the arbitration compensation was refused on the grounds that the negligence committed in the cottage hospital constituted a novus actus interveniens; hence the present incapacity was due substantially to bad medical treatment and not to the original injury.

THE SOLICITOR

Whereas the doctor takes a rather detached view of any question of compensation, the lawyer jealously watches his client's economic interests. In many instances solicitors have been grossly misled by medical certificates

---

ridged from a paper read to the Wrexham and District Clinical Society.

clinic in the U.S.A. It was closed by the police in ten days, and Margaret Sanger and her associates went to prison, where they hunger-struck and appealed, and won a small momentous decision: that if she had been a doctor it would have been all right to give advice on contraception to married people for the cure and prevention of disease. This was the first crack in Comstockery, and it widened fast to let in daylight. The clinic was opened again under the charge of Dr. Hannah Stone, who remained there till her recent death. There are now some 600 clinics in the United States, several hospitals are legally able to give contraceptive courses if they wish, and the whole attitude to the subject has become more rational.

Those who listened to this indomitable and charming speaker recounting her campaigns found it easy to recognise the qualities that have brought her victoriously through them.

A NEW DISEASE?

From Australia comes the report of a new mycobacterial infection in man.[1] During the last few years 6 patients have been seen in rural districts of Victoria with an indolent ulcer of the extremities suggesting tuberculous infection. Microscopic examination showed very numerous acid-fast bacilli, which could not at first be recovered on culture and which were not pathogenic to the guinea-pig. Indeed their appearance was reminiscent of *Mycobacterium leprae*, but the clinical picture was unlike that of leprosy. This diagnosis was definitely excluded, first by injecting into the rat infected material, which gave rise to ascites and superficial lesions of the legs and scrotum, and secondly by successful cultivation of the organism, at 33°C, on several media suitable for *Mycobacterium tuberculosis*. The epidemiological picture is far from clear. Although 4 of the patients came from a single rural neighbourhood and the other 2 from a second, no common factor of contact or association could be found; and no disease which could be connected with their's was detected among animals in these areas. Search for previous accounts of any similar disorder brought to light only a remark that in one part of Queensland several patients had been seen with a single small ulcer containing "organisms indistinguishable from *Myc. leprae*." The present report certainly seems to justify the authors' claim that this disease has not hitherto been recorded. Apart from poisoning by one of the new agents in industry, a new disease is most likely to be due to an organism which either has newly learnt the art of preying on man, or else is so rare or has so remote a habitat that it has previously escaped detection.

GLYCOSURIA IN PREGNANCY

That glycosuria is found more often in the pregnant than in the non-pregnant woman has long been known; but the mechanism and the frequency of this phenomenon are still uncertain. Using Fehling's test, Weiden [2] found sugar in 6·9% of 172 specimens from non-pregnant women, compared with 29·6% of 340 specimens from women in the first trimester of pregnancy, 19·8% of 51 specimens in the second trimester, and 21·4% of 145 specimens in the third trimester. Of a small series of 39 women in whom the urine was tested throughout pregnancy, 9 had glycosuria which disappeared towards full term. The effect of the ingestion of 50 g. of glucose upon the incidence of glycosuria was investigated in 102 patients, of whom 11% had glycosuria in the fasting specimen during early pregnancy, and 15% had glycosuria in the later months. After ingestion of glucose, glycosuria was found in over 60% of the entire group. The fasting blood-sugar of 103 pregnant women ranged from 40 to 120 mg. per 100 ml.; but in 38% of these the level was 80 mg. per 100 ml. or lower. Of 24 women who were re-examined after the end of pre 19 had a fasting blood-sugar of 90 mg. per 100 ml.

Glucose-tolerance tests were done on 102 In almost half of the 38 without glycosuria, the figure during pregnancy did not exceed 140 mg. 100 ml., and in almost every case the curve had to normal a year after the end of pregnancy. The threshold was lowered in 33; and 19 had curves as "renal glycosuria with superimposed diabetes" the blood-sugar did not return to normal within hours, yet the maximum figure never exceeded 180 per 100 ml. Post-partum curves in these patients of the same type. In 7, curves resembling the lag-curve, with peak figures exceeding 180 mg. 100 ml., were obtained.

The striking feature of these observations is frequency of lowered glucose tolerance, even in without glycosuria. Laferty [3] has suggested four that may be responsible for the phenomenon: (1) withdrawal of glucose from the maternal blood nourish the fœtus; (2) excessive consumption of by the mother; (3) excessive withdrawal of from the maternal blood through over-produc insulin; and (4) insufficient supply of glucose faulty alimentation. Of the many other theories have been advanced, two are controverted Melbourne findings: one is that this due to excessive mobilisation of glucose, and th that a raised blood-sugar plays an importan These findings imply that restriction of intake during pregnancy is fraught with the acidosis. They do not invalidate the sound rule glucose-tolerance test should be performed on pregnant woman with glycosuria.

BIRTHDAY GREETING

To mark his 80th birthday, Sir John Parso presented with his portrait at a reception held honour at the Royal College of Surgeons, Inn Fields, on Sept. 3. The portrait, which was by Mr. John Gilroy, was the gift of the Fa Ophthalmology and of the Ophthalmological of the United Kingdom.

It is given to few men to excel in all the b of their specialty as Sir John Parsons has don advice has been sought by patients all over the and his views on scientific problems are acc physicists and physiologists alike. His work on vision is still perhaps the best unbiased account conflicting theories of other workers, and for his on the theory of perception and of illumination elected president of the Society of Illuminating and admitted to the fellowship of the Royal —a rare distinction for a practising clinician represented British ophthalmology to other and the Medical Research Council regarded him of their most valuable members. Indeed he in the council in ophthalmic research and has seen that that interest was maintained up to the present Now his dreams are coming true—two of them recently in the shape of an Ophthalmic Institut the establishment of the F.R.C.S. in ophthalm His colleagues, who are still his students, are have his encouraging smile to cheer them on, the profession join in their wish of "Many more birthdays."

The Index and title-page to Vol. I, 1948, which completed with The Lancet of June 26, is preparation. A copy will be sent gratis to subs on receipt of a postcard addressed to the Manag The Lancet, 7, Adam Street, Adelphi, W.C.2. scribers who have not already indicated their de receive indexes regularly as published should do so ned a fracture of the terminal phalanx of his ring finger ruising of his thumb leading to osteo-arthritis.

[3] Laferty, J. M. *Amer. J. Obstet. Gynec.* 1931, 22, 63

the county-court arbitration three years later it was ed there was now a subluxation of the carpometacarpal of the thumb. An expert witness for the workman evidence to this effect and produced radiograms of both to support it. In addition he stated that the radiologist ositioned the hand specially to show the subluxation ad reported its presence, and a radiogram of the other b had been taken for comparison.

en I had previously examined the thumb I had not found ubluxation, and I examined it again in court with the negative result. Inspection of the films produced made ar that the film of the left thumb did not show any subion. Moreover it was impossible to make any exact arison with that of the right thumb, since it was not in ilar position, as could be seen by the way the shadow of ight thumb was superimposed on that of the index, eas that on the left side was not. I pointed out that the logist was well known to me, and I was sure he would ave given any opinion about a subluxation on those and I refused to accept the statement without seeing eport. The report was not produced. Nevertheless the man was awarded a small weekly payment for partial acity.

e radiologist's report turned up later. It merely stated there was slight osteo-arthritic changes in the metacarpo-ungeal joints of *both* thumbs. There was no mention of arpometacarpal joint or of any subluxation.

ese examples emphasise the necessity for a long and experience of all varieties of injury, particularly in which there is no question of compensation. For y years I kept records exemplifying all types of lation and deformity. It was a never-ending source terest to see the wonderful adaptability displayed. of the most amazing was a plumber whose hands apparently totally crippled by gout. Both hands almost completely clenched owing to contractures the fingers and both thumbs; he could just separate tips of his fingers from the palm for about $^1/_2$ in.; yet I saw him "wipe" a joint on a leaden water as well as any plumber could.

ny such patients would obtain substantial comation or heavy damages if there were any question jury. Sadder to relate, it is unlikely that they d be any longer usefully employed.

ASSESSMENT OF DISABILITY

bles have been drawn up giving the percentage ility for various amputations of the limbs, from a r to the whole limb. In practice these methods seless. For instance, loss of a finger would be very us to a violinist or a pianist, but comparatively al to a porter or a dock labourer. Each case should ealt with on its merits and with regard to the type ork involved or possible. Here again a fairly wide aintance with different pursuits, crafts, and labour tremely valuable.

here is also an unfortunate tendency to classify any ticular injury in terms of its most serious or comted manifestation and to ignore the simpler types. tures of the os calcis are notorious in this respect: e that are comminuted and involve the subastrad joint with subsequent arthritis live up to their reputation and cause serious permanent disablement; eas simple breaks through the posterior part of the which do not involve joints cause little if any bility.

se 6.—An R.A.F. pilot on a visit to a lady friend found nvenient to leave by the window to avoid embarrassing lady's husband. This involved a drop ot about 20 and caused fracture of the os calcis on both sides. rtheless he was fit for duty three weeks later.

actures of the spine also vary enormously in the real bility they cause. Most cases, even of crush fractures e vertebræ, may cause little incapacity once they onsolidated, whereas the comparatively trivial fractures of the lumbar transverse processes often draw compensation for two or three years.

MEDICAL REFEREES

It might be thought that the appointment of medical referees would have avoided many of the difficulties I have described. Unfortunately this is not so, and the explanation is simple. First, no one man is sufficiently experienced or qualified to act in all cases; this could be got over by appointing specialists in each branch as required. Secondly, the remuneration is wholly inadequate, compared with the likely earnings of an experienced man (and it is obviously no use appointing anyone who is inexperienced). For these reasons we find a general practitioner or a physician acting as umpire in surgical cases in which their teachers often appear as experts. No wonder many eminent physicians or surgeons refuse to touch compensation work, whereby they might be made to appear ridiculous.

MALINGERING

When the claimant is malingering, a particular movement of a joint, ability to bear weight, &c., may be observed only once in the consulting-room, after which the claimant is on his guard, and in court it may not be possible to demonstrate it again. Alternatively, if it is successfully demonstrated, the judge, counsel, &c., often miss the point from lack of medical knowledge.

A malingerer seldom gives himself away so completely as in the classical case in which the counsel for the employer, during a gruelling cross-examination, suddenly asked: "You say you have been unable to raise your arm at all since the accident—well, how high could you get it before?" Without thinking, the man instantly put his arm freely above his head.

APPRECIATION OF MEDICAL EVIDENCE

Anyone with a sense of history must look with some envy on the medieval mummery lingering in the courts and think how wonderful it would have been to see a surgeon performing a gastrectomy in a full-bottomed wig. But why after having administered the oath with all the solemnity of bell, book, and candle, do they

> "Assume that the witnesses summoned in force
> In Exchequer, Queen's Bench, Common Pleas, or
> Divorce,
> Have perjured themselves as a matter of course"?

The plain fact is that medical evidence is appreciated only with great difficulty, if at all, by lay tribunals. In these cases the doctor is in a false position; after years of training in scientific methods his clinical observations and opinions are judged by men whose whole outlook has been classical and academic and who, like the schoolmen of the Middle Ages, are more conversant with books than with nature. For instance, I have heard eminent counsel argue that, since the practitioner had examined a patient many times, he must know more about his injury than the expert who had examined him only once. And even a county-court judge once claimed that two general practitioners and a house-surgeon were a good working majority against an experienced surgeon in a complicated surgical case.

CONCLUSIONS

Cases of injury involving compensation are essentially difficult and should receive specialist attention from the beginning and during rehabilitation.

It is unfair to expect general practitioners to treat or assess disability in these cases.

The suggestion in the new Act to remove these cases from the courts is strongly supported by medical experience in the past and, so far as assessing disability is concerned, should include common-law cases also.

based on inaccurate diagnoses from various causes but chiefly from lack of special experience in these cases. They can scarcely be blamed therefore if they take up weak or even mistaken cases at times. There is unfortunately another side to it, and when it is remembered that it costs at least £20–30 to defend a county-court action, it is not surprising that in about 98% of cases the employer submits to the workman's claim being settled without a judicial decision. As Collie asks, "Is it unreasonable to suggest that a large proportion of the cases in the 98% are settled by processes which might be described by an ugly word?" Colour is lent to this view by the obvious preparation some workmen have undergone before they come for a medical examination. In fact their solicitors have such a poor opinion of their case that they have been told not to answer any questions at all for fear they should give themselves away.

WHEN DOCTORS DISAGREE

It has become a byword that doctors agree to differ, and it must often appear to the legal mind, untrained in medicine, that opposing medical experts were disagreeing about simple facts without any apparent justification. As Kitchin says, "One of the saddest sights in the administration of justice is two processions of medical witnesses, one on each side, in a personal-injury case or a murder trial where the prisoner has pleaded insanity, flatly contradicting one another on fundamental matters of fact." [2]

In these cases, however, there is plenty of room for wide differences of opinion, even when the opposing witnesses are evenly matched in training and experience. When, as so often happens, one of the witnesses, either so-called expert or general practitioner, is expressing opinions on subjects of which he cannot, from lack of training or opportunity, have any adequate knowledge, it is not surprising that agreement cannot be reached.

Case 3.—A man, aged 31, stated that in February, as he was passing a stationary lorry on his pedal cycle, the driver of the lorry opened the offside door and knocked him off his bicycle, and he sustained a sprain of his left wrist, bruising of his left hip and knee, and a sprain of his left ankle. He was able, however, to pick himself up and, after talking to the driver, rode his cycle home. He consulted his panel doctor, who treated him, but he was not referred to any hospital. In March, exactly a month after the accident, he was referred to me complaining that he had no grip in his left hand, his left hip was sore, and his left knee very painful. The ankle was better, though it had been swollen.

His general condition was fair, though he was poorly nourished; and there was no sign of any traumatic neurasthenia. He had a bandage round his left wrist, but the joint was normal in all respects, and there was no limitation of movement of wrist or hand. All bruising about the left hip had disappeared, and movements in all directions were free and painless. There was a bandage round his left knee, but the joint was cool to touch, there was no swelling or effusion, all movements were free and painless, and there was no wasting of the thigh muscles. The left ankle was normal, and he bore weight well on the limb, though at first he pretended he could not do so.

I reported that he was malingering; from the history of the accident he could not have hurt himself much; otherwise he could not have ridden home. Moreover his demeanour was unsatisfactory, and he was very guarded in his answers to questions and appeared to be lying most of the time. Even when I asked him if his bicycle had been damaged, he had to think for quite a time before he said it was not.

In September his solicitors wrote to say the case was down for hearing at the forthcoming assizes. They enclosed a report from the medical officer of a county hospital to the effect that the patient had been admitted in mid-August with a history of frequency of micturition, hæmaturia, and pain in the lower abdomen dating from May (three months earlier). Radiography suggested renal tuberculosis, and this was confirmed by finding the bacillus in the urine. In the opinion of the medical officer there was no evidence of any disease or disability following the accident and no connexion b it and the tuberculosis of the kidneys.

At the trial in October two general practitioners a medical officer of a sanatorium, to which the patient the meantime been admitted, gave evidence to the that the shock of the accident had caused an anxiety which had lowered his resistance to tuberculosis, whi been latent before the accident. Against this purel jectural assumption the following facts were (1) From the history of the accident there was no of any serious injury or shock; (2) when the patie carefully examined exactly four weeks later, there sign of any injury, no abnormal mental state, and n plaint of any urinary symptoms; (3) in tuberculosis kidney urinary symptoms appear early, whereas i case they did not arise till May, 3½ months after the injury; and (4) renal tuberculosis is a blood-borne and the evidence is against trauma being an factor—in any event there was no evidence of any inj either kidney in this particular case.

The judge thought the disease was bound to co sooner or later, but he was satisfied that the accident direct cause of the anxiety neurosis, which in turn the onset of the disease, which would probably cause earlier—perhaps much earlier—than otherwise would case. The plaintiff was awarded £1568 damages.

A case of this kind is a fairly straightforward problem, and any fully trained surgeon would little difficulty in coming to a contrary opinion o facts. For a layman without that scientific train would be impossible to assess the surgical issues c expertise of the various witnesses. I therefore d complain that the workman was given the benefit doubt. I am mortified that the "doubt" should on such an old cobweb as "anxiety neurosis."

Case 4.—A workman, aged 45, was holding the of a handcart while it was being loaded. By a very heavy weight was suddenly dropped on the the shafts went up, carrying the workman with them then dropped again as the weight rolled out; he heavily on his feet. Though he complained of some p continued working for several days, limping on his leg. He then ceased work, was examined by various do and was treated at different hospitals until, about months later, he was referred to me. He then comp weakness and twitching of his right leg. Even while sitting quietly in a chair his right leg was constantly and his right heel tapping on the floor.

Examination revealed no sign of any organic lesion when his attention was distracted the clonic spasm leg ceased. I reported a functional condition; this was and before the arbitration a well-known orthopædic was asked to examine him. He did so and agreed to the hearing. The evidence on the other side was to the that the workman had an organic nerve lesion as the of the accident. This was supported by a Ministry of P neurologist, who averred in evidence that all reflexes absent in the affected limb. We denied this, and the decided that, since the medical evidence was so mu variance, he would see the man in his private room to the medical witnesses to demonstrate their findings.

The patient was laid on a wooden table, his right beating a tattoo all the time. The Ministry of Pe neurologist showed that it was impossible to demonstrat of the reflexes owing to the great spasticity and clonic in the limb. The orthopædic surgeon was faring no b when I remembered that if the patient's attention wa tracted the clonus would probably stop. I therefore w over to him, tapped him on the shoulder, and said "I th you told me the handcart was painted red when as a mat fact it was green." He was so indignant at this gross statement that he at once became involved in a sp argument, during which the limb gradually ceased twit and the orthopædic surgeon was able to demonstrat Babinski, patellar, and gluteal reflexes and to show there was full movement at all joints and no spas whatever. While the neurologist was being revived judge remarked that "Whatever the man was suffering he was satisfied it was not an organic nerve lesion."

Case 5.—A dock labourer, aged 72, was said to have ha left hand trapped between a stanchion and a skid and to r the successful building and establishment of a h centre, agreement and coöperation are needed en the health authority, the executive council, and cal doctors. Such agreement, we understand, has achieved in Birmingham. The plans originating the health authority (the Birmingham city council) been approved by both the executive council and ocal medical committee. Both these latter bodies nxious to see the centre built as soon as possible, they are willing to coöperate fully in arranging for medical staffing of the centre. *The number of doctors who have already expressed their willingness* (subject to satisfactory negotiation with the Ministry of Health as to conditions and terms of service) to work in the centre when it is built is sufficient for the city council to embark without qualms on their project as soon as the sanction of the central authorities has been secured.

---

[2] Kitchin, D. H. *Med. Annu.* 1942, p. 208.

This considerable progress makes all the more regrettable the controversy which has arisen, and is still unresolved, between the sponsors of the centre and the Ministry of Health over the potential use of the health centre by private patients as well as health-service patients.

Disabilities

12. BLINDNESS

une, 1944, at the age of 30, I was totally blinded ying bomb, also receiving multiple injuries to my hest, and arms. I had been married for four years. d a baby daughter of nine months. After four s I was discharged from hospital and began g at St. Dunstan's. I left the training centre in 1945, and in the following September started ment with a large firm in the Midlands.

d not lose consciousness immediately on being hit, tried to see what had happened to the other nt of the room. I couldn't, and therefore experi- my first fear that I had lost my sight. I had my confirmed in hospital, when the surgeon told me e had removed my right eye, and that it was unlikely he other would ever be anything more than orna- l. There was a remote hope that some sight might to my one eye, but I never really counted on it, gh I secretly tried all sorts of experiments on f, such as trying to discover whether I could see ining a torch under the bedclothes. The net result hat I knew the worst very early on.

annot deny that the realisation hurt like hell at , and that I had my periods of intense depression, everything worth while seemed lost. It hurt to that I should never again see my wife or my daughter, of whom I had seen so little during the years. Looking back, two principal things helped fight off, and avoid showing, this depression—the ling courage of my wife, who from the first showed I should not have to carry my burden alone, and wn determination not to be a burden to others.

wife was at my bedside when I recovered conscious- n hospital the morning after I was hit. Her readiness ce the future cheerfully was an immense help in mining *my own reactions to my changed circum-* ces. We weighed up our assets and decided that we d still make a success of life. We agreed to present erful face to the world and help each other in doing so. timulated by the cheerful banter of a fellow officer in next bed, I soon started to do things for myself. I d I could light a cigarette by sliding my thumb g and feeling for the end with a lighted match, gh I had an unreasonable fear that I would burn face or damage my bandaged eyes. I signed all the rs written for me by my friend. With a tremendous t I wrote a letter in longhand to my wife. I began orm habits to make *life easier—to put round things* n where they wouldn't roll away, to remember re I had put such things as my razor and shaving soap d I also began to take a more intelligent interest in gs around me. I got people to describe the hospital the surrounding district. Thus I built up my own tal picture. I learned how necessary it was for ted people to be accurate in their descriptions; shod ones were worse than none at all.

ome things I had to learn by painful experience. A ision with the corner of the bed when I was picking a shoe taught me that it is advisable to ensure that there is nothing in the way before bending down quickly. My first solo journey on a bus at this time taught me that it is as well to make sure that no-one is occupying the seat on which one proposes to sit. I landed on the lap of a young lady, who fortunately did not take too serious a view of the incident. An embarrassing moment when I tipped the contents of my plate on to my lap brought home to me that a blind person must constantly guard against the tendency to pull the food on his plate towards him during a meal. With my sighted intimates I adopted a system by which they said "six o'clock" if I was in danger of pulling the food off the near edge of my plate. At first I used to get them to describe, as though they were describing a target, the location of food on my plate. "Six o'clock beef, nine o'clock potatoes," and so on. Later I found this unnecessary, though this mode of locating things is useful generally at table. I do, however, like to be told what food is placed in front of me. Some blind people like to have their meat cut up, but I prefer mine served in the ordinary way, even though this sometimes presents difficulties. It was some time before I appreciated that the safest way of approaching one's glass was from above with the fingers slightly extended.

In hospital, I learnt to use my ears more acutely, to use sounds to help me build up my picture of the things round me and so to establish landmarks for finding my way about. Later, when I became more competent in walking about on my own, I began to distinguish the subtleties of echoes thrown back by lamp-posts, walls, and other objects. It was a great thrill when one day I thought I detected a difference in sound indicating that there was an object on my left. I investigated with my stick, and was jubilant to find that there was, indeed, a pillar-box there. I also learnt other devices for getting round on one's own: using the camber to walk along a quiet road, the value of counting one's paces, how to tell the proximity of objects by the difference in air-pressure, *and the wisdom of taking a complete turn round a* corner before attempting to cross a road, so as not to wander into the middle of a cross-road.

I had been taken under the wing of St. Dunstan's three weeks after being hit. The attitude of my fellow St. Dunstaners was a fine stimulus. They had no sympathy for themselves, reserving their sympathy for other patients in the hospital. With them, in hospital, I learnt to type and read Braille. I experienced an awful fear that I should never develop my sense of touch. For a short time I was horrified to find that I could not distinguish the Braille formations, but the thought that *this* was the *only* way out of *illiteracy* kept me going. Soon I was happy to find that I could read again. Later, I did carpentry, learnt Braille shorthand, played the piano, went horse-riding, and took part in athletics.

One of the biggest problems has been how to adjust one's relations with sighted people. This was particularly difficult in the early stages, when I longed to do things on my own, and well-intentioned but *misguided* people would try to help me. Once I had acquired confidence in finding my way about I was glad to welcome assistance. Sighted people can be particularly helpful by guiding one in the correct way. I personally dislike being propelled

The medical tribunals should be carefully chosen from among specialists with wide experience in treating and examining these cases; though they must not, of course, assess the disability of their own patients.

If the new Act will remove workmen's compensation cases from the courts it is to be welcomed. But unless the personnel of the medical boards is very carefully selected there may be great hardship for many working men, or alternatively a third of the population may become pensioners of the remainder.

DISTRIBUTION OF STREPTOMYCIN

THE Ministry of Health announces that in future streptomycin will be allocated and distributed by regions. In each region beds in stated hospitals "will be so staffed and equipped as to ensure the necessary scientific control of the treatment. It is therefore hoped that, so far as possible, doctors having suitable patients will endeavour to admit them to these beds." The number of beds and cots allocated and the distribution centres are as follows:

Region	*No. of beds*	*Distribution centres*
Newcastle	68*	General Hospital: Mr. Wing, chief dispenser (Newcastle 35211). Royal Victoria Infirmary: dispenser (Newcastle 25131). Pathological Laboratory, Cumberland Infirmary, Carlisle (Carlisle 590).
Leeds	68	Blood Transfusion Laboratory, Bridle Path, York Road, Seacroft: Dr. T. S. Marshall (Leeds 45091).
Sheffield	74	City Hospital, Hucknall Road, Nottingham: Dr. W. Morton (Nottingham 66292).
East Anglian	38	Addenbrooke's Hospital, Cambridge: Mr. Hopkins, chief pharmacist (Cambridge 4451).
North-West Metropolitan	138	West Middlesex Hospital, Twickenham Road, Isleworth: Miss Bristowe (Hounslow 2311).
North-East Metropolitan	64	Mile End Hospital, Bancroft Road, E.1: Dr. W. G. Sears, physician-superintendent (Advance 2873).
South-East Metropolitan	67	Grove Park Hospital, S.E.12: Dr. M. H. Logg (Lee Green 1547).
South-West Metropolitan	66	South London Blood Supply Depot, Benhill Avenue, Sutton: Dr. E. G. Murphy (Vigilant 0068).
Oxford	80	Churchill Hospital: Mr. Trillwood, chief pharmacist (Oxford 48651).
South Western	56	Ham Green Hospital and Sanatorium, Bristol: Dr. J. Macrae (Bristol 31165).
Wales	57	Cardiff City Isolation Hospital: Dr. Emrys Harries (Cardiff 960).
Birmingham	90	Selly Oak Hospital: Mr. R. P. S. Kelman, medical superintendent (Selly Oak 1361).
Manchester	60	Royal Infirmary: Mr. J. B. Lloyd, chief pharmacist (Ardwick 3300).
Liverpool	50	Fazakerley Sanatorium: Dr. O. F. Thomas, medical superintendent (Aintree 2324).

* Incomplete return.

The Ministry suggests that the greatest potential danger is the production of streptomycin-resistant strains of *Mycobacterium tuberculosis*. "Thus a patient with very early pulmonary disease who might have responded to other recognised forms of treatment alone but who is given streptomycin 'prematurely' may be found, in the event of relapse or extension of the disease, to be beyond the reach of streptomycin treatment. From the public-health point of view there is clearly a risk of old chronic cases spreading infection with streptomycin-resistant strains, so that patients acquiring meningeal or miliary tuberculosis from them cannot hope, in their turn, to be benefited by streptomycin treatment."

THE BIRMINGHAM HEALTH CENTRE

MOST local health authorities, their housing still unsolved, have been only too ready to set aside provision of health centres as at present im Where an adequate service (though it may not coördinated one) is already provided from surgeries and municipal clinics, building and difficulties preclude any ambitious schemes for improvement of medical facilities. But where are inadequately served, or are outgrowing their services, new arrangements have somehow to be either by communal planning or haphazardly (as in past) by allowing doctors migrating to the find or build *accommodation for themselves*. T our most influential public authorities, in Lond in Birmingham, both concerned with the provi new housing estates, have decided to make the centre the key to the medical services for their communities. The London County Council has a the building of a health centre on its new Woodberry Down, Stoke Newington, and the city council has sanctioned a centre at Stechford

In some ways the Birmingham project has the immediate interest, for it has been planned f struction as a single-story building built from st prefabricated units. Materials are available *building and little skilled* labour is required erection. It should then be possible for it to b and brought into commission with little delay provide a valuable testing ground for group practice. If, too, the prefabricated buildings satisfactory, the plans and layout of the Bi experimental centre may well be copied with tions wherever a suitable site of sufficient size is Single-story buildings admittedly demand sites in urban areas seem of wasteful size, but in years t when more permanent buildings come to be may well be grateful not to have to fit them into veniently cramped sites. It is to be hoped, that when the Birmingham centre is built it will many municipal inquirers and not a few imitators

The centre will serve some 20,000 people. The site, of about two acres, is easily accessible by bu cars. The centre will be built of Orlit prefabricate around three sides of a square enclosing a fore on the fourth side. It will be finished externally in roughcast, and internally in flat oil paint in pastel Decorative schemes in the general-practitioners' vary, and consideration will be given to the doctors' taste and requirements. These suites, six in numb (with a minor-operation room, a recovery-room, room, office, records-room, dispensary, and lab occupy one wing of the centre. Each suite will a consulting-room, an examination-room, and a waiting The central block will house clinics for *maternity* and welfare services and will include a lecture-hall, a to nursery and playground, accommodation for sunlight ment, and a pram-park. The remaining wing has a clinic, accommodating two dental surgeons, a caretaker and the common-rooms for the staff of the centre. consist of a doctors' common-room, a medical library, common-room, staff dining-room and kitchen, and comprising a bed-sitting room and bathroom for *the* on duty.

Architect's drawings of the proposed centre appeared in the Birmingham press, and a detailed was published in the *Medical Officer* for Aug. 14 (p From these it can be seen that the design, whi the work of Mr. Donald A. Goldfinch, architect t city of Birmingham health committee, is both tionally sound and architecturally attractive. It plan, too, which if successful in Birmingham easily be changed—by alteration in grouping or int division of its component units—to suit larger or communities or other sites.

erpreted by a fellow outpatient as "Double Tuber-ous Consumption of the Ankle" (though it only meant o come again in two days").

lost abbreviations are unnecessary: thus, if a patient's ier is well it takes ten letters to write "father well" eleven letters and two stops to write "father a. and yet every student prefers the latter form. (Surely if body is well we can take it they are alive.) Probably vorst offenders are chest experts, with their P.P.'s, , and P.C.'s, expressions which they use in speech vell as when writing. Ophthalmic surgeons are y bad too, and I remember one who wrote his ons on my cases almost entirely in single letters e alphabet. I cured him by sending him a request .T.M.I.T.P.N.G. (Please will you tell me if this nt needs glasses).

ere is one kind of abbreviation which I think be used a lot more. I mean the word made of ls, so much used in the war (PLUTO=Pipe lines r the ocean and FIDO=Fog, intensive dispersal of). nedicine we have only two of this kind—EUSOL ding for Edinburgh University Solution, and BIPP Bismuth, Iodoform, and Paraffin Paste. May I est (neurologists please note) getting rid of dysdiado-hesia and having DITHER (Difficulty In Twisting ds Equally Rapidly).

Letters to the Editor

STUDENT SELECTION

SIR,—The rush to join the medical profession has created for the psychologists a problem which on their own admission will keep them pleasantly occupied for many years to come, and which will no doubt provide jobs at the public expense for many recruits to their ranks. This new research will, it can be confidently predicted, go the way of all other research, spreading in endless ramifications and never reaching finality. Already there is adumbrated the first extension—research into the selection of people suitable for the selection of people suitable for the pursuit of medicine. And so it will go on and on. The possibility of raising the percentage of "outstanding" students from 10 to 39, envisaged by Mrs. Petrie (Aug. 28), illustrates the lack of logic which characterises many of the emanations from our laboratories. For when 39% are outstanding against 61%, it will be our proud boast that never were so many outstanding against so few. The problem will be solved, not by the tests, matrices, and screenings of the psychologists, but by the study and correction, by minds untrammelled by the jargon of modern science, of the motives behind the abnormal desire for entry. The chief of these motives are four: snobbishness, the lowering of financial barriers, the call of idealism, and the search for economic security.

In regard to the first and second, the easier the climb, the greater the number of climbers; we can only hope that the creation of new hills will ease the congestion on our own. To the idealism of adolescence medicine presents an appeal which is lacking in all other vocations except the Church. The doctor is noble and self-sacrificing, a beacon of virtue in this sinful world. In contrast, the business man is selfish and avaricious, flourishing on the exploitation of his fellow men. A young man just down from Oxford told me with great joy that he had obtained a post in hospital administration. "There," he said, "I shall be doing good in the world. If I had gone into industry I should only have been making money selfishly. I could never have stood it." His attitude shocked me, for I thought his university would have taught him better. It is, however, a view which is widely held. The inevitability of the association of trade with social injustice is a doctrine which dies hard, being perpetually fanned into flame by many of our sociologists, who keep harping on the evils of the industrial revolution. The headmaster of one of our leading public schools tells me that there are twice as many boys leaving to take up medicine as there are doctors' sons. Many of them embrace medicine scorning the family businesses where they are sorely needed.

To many parents financial security is a prime inducement. After all, the sick will always be with us whatever happens. These people do not realise that prosperity in medicine depends entirely on the prosperity of our export trade. There can be no security in medicine unless that trade is secure. We ought to view with grave concern the prospect of the most intelligent of our youth being encouraged to shun commerce as something unsafe and unclean, and to seek financial security and moral salvation in a profession completely dependent on commerce. We may question whether the attempt to cream off the ablest into medicine is in the highest national interest.

We must learn to see medicine and the community in their proper perspective. We must realise that, intelligence being limited in quantity, medicine cannot be enriched without the impoverishment of other vocations where it is needed just as much. We must educate youth and parents in a saner, more realistic, and less sentimental outlook. The headmaster mentioned above, seeing the danger with a prescience unfortunately lacking in the leaders of our profession, has shown the way. He has instituted lectures by men prominent in agriculture and industry with the object of teaching boys that in those fields there are opportunities for the cultivation of moral and intellectual qualities as great as or even greater than those existing in medicine.

by the shoulders. I prefer to take the arm of the person guiding, so that I am slightly behind him; this makes it easier to avoid obstacles and to be ready for steps up or down. When being shown a chair I like to have my hand placed on its back. In conversation I deprecate the avoidance of words such as "see" and "look."

Apparatus which has been invaluable to me in my job has been a typewriter, Braille shorthand machine, pocket Braille frame for making memo notes, a Braille writing machine, a stock of thin cards about 5 inches by 2 inches, Braille watch, and, of course, my walking-stick. The cards are used for making Braille notes on the pocket frame or for making longhand notes with a pen or pencil. I use a ball-pointed pen so that there is no need to discover which way round to hold it.

Some blind people do not try to keep up their longhand writing. This seems to me a pity. I have managed to continue to write as automatically as I did when I was sighted, and I have found this, and similar operations such as playing a piece of music which one has memorised, fairly easy if one does not consciously think about the operation.

Performing actions naturally, as one did when sighted, is an aim that I have tried to follow in as many directions as possible. Thus, unless there is need for special care, I prefer to walk along using my walking-stick as a sighted person would, swinging it to the right or left if necessary to maintain contact with a wall or grass verge.

* * *

It may seem that I have minimised the difficulties. These have, of course, been perpetual, and some phases have been harder than others. Periods of insomnia have coincided with periods when I was making the greatest effort. At times I have felt the need to relax and be content to sit and do nothing.

My work and my family have not given me much leisure time. The leisure activities of blind people can be legion, so I will mention only the more unusual forms I have sampled. These include high diving, surf-riding on the Cornish coast, aquaplaning, and attempts at playing billiards, snooker, and table-tennis. The last three were failures, but the attempts were amusing.

One of the compensations of blindness is finding ways of overcoming it. Using a dial telephone was at first a laborious process, until I found that all four fingers of the right hand could be employed to facilitate the operation. An aluminium frame, with appropriate spaces, enables me to make out my own cheques. The difficulty of distinguishing between a ten shilling and a pound note was overcome when I found that one could measure the width of the note unobtrusively by passing it between the first and second fingers.

It was some time before I plucked up courage to help my wife with the children—now a girl of 5 years and a boy of 20 months. One has to maintain a hundred per cent. concentration and one must be sure of one's terrain. It is advisable to take some special precautions—to approach a child with one's fingers curled, to back through a doorway when carrying a child, to hold on to the bannisters firmly with one hand when carrying the infant downstairs—but the result is a tremendous gain to any blind man who is fond of children. Ingenuity is needed to devise ways of playing with children, and one has to be constantly on the alert, but the blind man can tell stories with the rest, he can make models in wood or cardboard using his sense of touch to guide him, and many other things besides.

To summarise, I would say that the first essential is to accept cheerfully your changed position. Milton was a striking lesson in this, and many would find his "Sonnet on my Blindness" as helpful as I did. The next thing is to regard yourself as a normal person with extra difficulties and persuade others to accept you as such. The rest is patience, perseverance, and a sense of humour.

In England Now

A Running Commentary by Peripatetic Co

THE boarding-house abutted on a triangle of and it was when I chanced to look out of the b window towards the edge of this that I saw the p His handcart was abandoned by the roadside, and he but his upper end which I could not see for grass nettles, was twitching violently. His boots were de ing circles in opposite directions. Now and then the phase would succeed the clonic.

It is all very jolly to rush out and administer —all very jolly, that is, if you qualified last week other things weigh in the mind against a Hippo rush to stick one's neck out—inquests two hundred from one's home town, persistent beggars complete hysterical fit, epileptics who prefer to be left to peace or who become pugilistic on recovering ness. But I had signed the visitor's book rather and everyone looked at me. "There's a man hav *fit*," they muttered in my direction. I went out.

The patient was lying full length in the grass *his head and shoulders down a manhole, struggling* tap. He met my gaze with an even stonier one, remarked that someone had fixed down this mate with a sanguinary monkey wrench. Anyhow, differential diagnosis on the way out had done me

* * *

My son, who is half way through his hospital his medical school, says in his last letter:

> "I didn't know that I had given you the that I was getting slack about work. The truth is have been completely 'had' about what our teachers are supposed to do. I had expected that would tell us what to learn and how to use our kn when it was learnt. Instead, each of them presents us *a single piece of a jig-saw puzzle, and leaves* it to build up the puzzle. It is just too bad if they give than half the pieces, and some of them badly cut.
>
> "I have now reached the same place that all seem to get to at about the same time. We realise no-one is going to give us a *comprehensive* picture subject and that the only thing to do is to plunge books, find the missing pieces, and then try to put together, still not knowing what the puzzle will when completed. It is a shocking waste of time, and money."

The fact is that medicine is one and indivisible. ophthalmologist may have the first clue to disease, the dermatologist to thyroid trouble, symptom of enuresis in a child may disclose a It seems to me foolish to stuff students with a of chemistry, physic, biology, anatomy, and ph and then consider that he is scientifically equipp deal with medicine.

* * *

Our radiologist is normally a cheerful fellow luncheon, but today he was prodding his fried *a moody sort of way and muttering* various letters alphabet to himself. We tried to cheer him up, b he would say was F.H.N.H. ? I.U.D. At first we tho it was some sort of spell to make him see better in the but at last we got out of him that he was suffering acute abbreviophobia, and that he had found the let written on an X-ray request form that morning. had no idea what part of the body to X ray. We t to be helpful: "Fractured Hand Now *Hurting* Unciform Decalcified" seemed ingenious but unlik "Four Horrible Nasal Hæmorrhages ? Investi Underlying Disease" suggested that a film of the n pharyngeal tract should be taken. Eventually, beca the request had come from a maternity ward, it referred to an obstetrician, who decoded it prompt "Fœtal Heart Not Heard. ? Intra-Uterine Death"

I think the radiologist was right to be annoyed. amount of irritation or confusion abbreviations caus greater than the time they save. They can be danger too. I have seen a nurse reading "guttæ H & C" preparing to put alternately hot and cold drops into eye. I have seen a patient with a sprained ankle on wh card was inscribed T.C.A. (2) having this comfortin om from the higher age-group, because they could more reliable answers to questions. In no case was a recurrence, and only 4 children showed any signs e location of the warts: these were in the form all localised callosities. Indeed most of the children orgotten the site of the warts, and several did not which foot. Advantage was taken at this examination of noting any associated foot abnormality. Slight lanus was found in 2 cases, and a moderate degree llux valgus in 6, but the position of the warts in cases could not be associated with the deformities. these children 36 used the swimming-baths all the round, and 15 in summer only; 39 used shower- regularly after physical training. Only 2 had communal gym.-shoes.

the many hundred cases treated before at the linic none have had to be referred for more energetic ures.

thout precise knowledge of the ætiology of plantar , preventive measures are mainly directed towards ding established cases from places which favour pread of this disease—i.e., swimming-baths and ers. The feet of children using such places should equently examined. It is doubtful whether the of disinfectants for the surrounds of baths and ers is of any value. In many affected children a ury stimulus, probably an abrasion, may have been iced by nails jutting into the shoe or by ill-fitting . It is therefore important that shoes should be rly fitted and comfortable.

e experience shows that (1) conservative treatment nently suitable for plantar warts and is the method oice for school-children; (2) chiropodists are com- t to deal with this condition, thus doing away the need for surgery under anæsthesia which s medical man-power; (3) other forms of treatment e the patient to risk of scarring and ulceration on re points; (4) little or no discomfort and very limitation of activities result from conservative nent: and (5) the expenditure of time and money ares very favourably with that in other forms of nent.

n indebted to Dr. A. T. W. Powell, M.O.H., Waltham- for his permission to publish these facts.

MELVILLE WATKINS
thamstow. Deputy Medical Officer of Health.

SHOULDER-GIRDLE SYNDROME

—In their article on June 26 Dr. Parsonage and ldren Turner did not mention syphilitic amyotrophy eir differential diagnosis. In view of this the ing case may be of interest.

miner, aged 47, reported to the medical outpatients' tment on July 27 with a history of being perfectly well 10 days previously when he was suddenly seized by a pain in the right shoulder, while sitting at home. The increased, reaching its maximum intensity in 48 hours making sleep impossible. It then spread to the neck uter border of the upper arm as far as the elbow; it lightly aggravated by movements of the shoulder, but by supporting the arm in a sling. Then, 4 days after nset of pain, he noticed some weakness of the arm which ally increased during the next week. There was no t history of trauma, malaise, headache, visual upset, or thesiæ.

amination showed slight wasting of the right deltoid marked weakness of abduction, although all movements shoulder were restricted owing to the severe pain. The and radial reflexes on that side were diminished, but iceps reflex was brisk. Sensation was unimpaired and her abnormalities were found in the central nervous n. The heart was moderately enlarged, and there was tolic murmur in the aortic area; X-ray examination chest showed generalised cardiac enlargement with tion of the aorta. Blood Wassermann reaction (W.R.) egative.

patient was admitted to hospital on Aug. 16. The ng of the right deltoid had increased and the right spinatus and infraspinatus were also involved; the however, was reduced to a dull ache and sensation ned normal. Blood W.R. was still negative; but the rospinal fluid contained 50 mg. protein per 100 ml., and 30 cells per 100 c.mm., and the W.R. was strongly positive.

This patient's symptoms and signs closely resemble those of the shoulder-girdle syndrome, and had not the condition of the heart directed our attention to a possible syphilitic ætiology the patient might not have been admitted for lumbar puncture; and thus the correct diagnosis would not have been reached.

CHALMERS H. DAVIDSON
Royal Infirmary, Edinburgh. NEIL S. GORDON.

CONTRACEPTION IN GERMANY

SIR,—At the Cheltenham Congress on Population and World Resources Dr. Durand-Wever's remarks about contraceptive clinics in Berlin referred only to the Russian Zone. Both from the platform and in private conversation she complained how odd it was that, in the British and American zones, not only were contraceptives forbidden but the passage of appliances and literature through the post was effectively stopped by the Control authorities; and that Allied governments were still continuing the repressive measures against contraception first begun by Hitler. This position is directly related to the figures given, of one abortion for every live birth. It would be unfortunate if your readers were to assume that in this terribly urgent problem freedom to limit the family existed in the British and American zones, where in fact such freedom is most effectively denied.

As one Dutch delegate put it, speaking of the time when, under the Germans, contraception was forbidden in Holland: "They made us contraceptually impotent." It seems a tragedy that in an area containing 65% women, according to Dr. Durand-Wever, and where the need is so urgent, the British authorities should continue the legislation initiated by Hitler.

Urmston, Lancs. B. SANDLER.

FAMILY PERIODIC PARALYSIS

SIR,—In 1901 Sir Farquhar Buzzard[1] gave in your columns an account of this rare disease in two young brothers and their mother. As the younger of the two brothers in this report I should like to describe an accidentally discovered means of alleviating the condition.

The attacks may be divided into two kinds: (1) ordinary, and (2) continuing.

Ordinary attacks are the more frequent, with sometimes as many as four in a day. Two of these would probably be local and very slight, not much more than a feeling. These attacks do not come on during muscular contraction, though the arms may be affected while one is walking. The immediate cause of an attack appears to be anything that lowers the vitality—for instance, exercise, hunger, cold, or diarrhœa. A slight attack may occur locally after the use of certain muscles, perhaps in a hand or arm, or in both hands or arms. A bad attack will affect all the muscles of the body, and a very bad one also affects severely the internal organs. The heart seems to flutter, the eyelids have a tendency to close, the back of the tongue seems to swell (I do not think that it really does), and swallowing and speech become difficult. Sight, hearing, and consciousness are not affected, but the whole of the body is helpless. Such an attack may last for an hour or more. After it is over there is a feeling of great rest and refreshment, and all tiredness felt before the attack came on has gone. Attacks are accompanied by an unpleasant but not painful sensation that I cannot describe; there seems to be a soft grip about it. Occasionally an attack comes on with practically no sensation, or a very slight attack may be accompanied by a lot of feeling. The likelihood of an attack gets less as the day advances, but one may occur in the night during sleep.

Continuing attacks sometimes follow ordinary attacks and are much the more tiring of the two. They may last for some days and are accompanied by a "beaten" feeling in the parts affected. They occur generally in the legs below the knees, either in the muscles in front of both legs or in those at the back of both. In either case walking is very difficult and exhausting.

---

[1] Buzzard, F. E. *Lancet*, 1901, ii, 1564.

We shall solve the problem only if we discard the narrow professional for the broad national point of view, bearing constantly in mind that our future prosperity depends on the attainment of a balanced society.

Cambridge. FE. ROBERTS.

SIR,—Your extract[1] from the paper by Dr. Fraser Roberts and Dr. Eliot Slater is wisely chosen. As a signature tune to the main subject of your educational number for 1948, might it not be rewritten thus:

> "Few would deny the advantage of a well-stored brain, a high power to correlate clinical observations with interrogation and laboratory reports, and to devise further investigations, an impressive manner, clear speech, and a good enunciation. Such qualities entitle their owner to submit his name for fellowships or clinical appointments at our teaching schools; but for the doctor, whoever and wherever he be, our aims are much less clear. There is needed a kindly heart, a gentle touch, the control to keep a confidence, love of children, with the power to make a decision and to accept responsibility."

Without these he is nothing. An experience of 38 years in trying to choose the best men for appointments at the end of their student career has shown the difficulty of selection by whatever means. Nor does psychology as yet offer any way whereby the desired characteristics may be foreseen five to seven years before they have to come together into action.

These younger men that today have in their hands the selection of medical students have indeed a hard task. But have they envisaged all that means? By the time we have responded to Wilfred Trotter's teaching that "it is no longer possible to conceal the wholly unique importance of medicine for the very existence of social life," I estimate the profession must be doubled. It is therefore not a problem of cutting down the numbers to those that the medical schools can hold, but of expanding the medical schools in size and number to take three or four times as many students as today until that number has been reached, and then stabilising them at double. Although the Barlow Report on Scientific Man-power did not specifically refer to medicine, the principles there laid down apply to us as much as to the qualified scientists with which it deals.

So far as I can see nothing has been done, as yet, in any way to attempt to tackle the problems of that report; and yet our continued existence as a nation must depend upon our efforts to do so as much as upon workers in mines, factories, and fields to increase production.

London, W.1. T. B. LAYTON.

BINOCULAR MICROSCOPES

SIR,—Dr. Shackle's letter of Aug. 14 is full of interesting observations, on which I have a few comments to make. But I would like to state clearly that what I am putting forward are only views and not carefully ascertained experimental facts.

The first important point is that whereas it is not tiring to use relaxed accommodation and parallel optic axes, or to use accommodation for 10 in. distance and convergence for 10 in. distance, it is also not fatiguing as a rule to change from one to the other. In other words, the idea that converging the eye axes after they have been rendered parallel, or vice versa, causes fatigue is, I think, wrong. The muscles are usually fully able to carry out these functions; presumably this is due to reciprocal innervation, which enables a muscle attached to one side of the eye to contract at the same time as its antagonist attached to the other side of the eyeball relaxes. The same statement applies to accommodation—that accommodation as such, from distant to near vision, or from near to distant vision, does not as a rule cause noticeable fatigue. What does cause fatigue is the necessity to accommodate for one distance and to adjust the eye axes for a different distance; and what is certainly in my case far more fatiguing still is the need for causing one field to be raised or lowered in respect of the other, to enable binocular fusion to take place. Whenever, therefore, I have experienced fatigue in using a binocular instrument it has been the vertical alignment have always scrutinised. I wonder if this is the of the discomfort that Dr. Shackle has experienced the converging type of microscope, which he in his letter? He might try putting prisms of angle, base-down or base-up, between one of the of this instrument and his eye, to see if this causes improvement.

To summarise: I cannot see any fundamental why the parallel type of microscope is superior or to the converging type. It may well be, however, one observer will have a personal preference for one than the other. If, having purchased one type, decided after further trials that the other type have been preferable, all that need be done is to suitable prisms above the tops of the eyepieces. the best results, these prisms should, of course, achromatic.

PLANTAR WARTS IN SCHOOL-CHIL

SIR,—In 1947, at Walthamstow, 94 girls and 56 with plantar warts were referred for treatment the school health service. Since the facilities for this and other foot conditions are widely known borough, this figure of 150 cases can be taken fair indication of the incidence of plantar warts school population of 16,463. The monthly rates January, 13; February, 11; March, 7; April, May, 10; June, 8; July, 7; August, 1; Sep October, 21; November, 21; and December, 16. low incidence in August is of no significance, for dances at all clinics during school holidays considerably, but the slight rise in the next three may have resulted from increased activities, swimming, during the summer months. The for the year in age-groups was: infants (aged 5–7 juniors (aged 7–11) 27%; and seniors (aged 66%. The increased incidence in the 11–15 is probably due to increased participation in training, swimming, dancing, &c.

The right and left feet were equally affected. of the patients had one wart only; 11 had warts on one foot, and 12 had multiple warts feet; 80% of the warts were in the plantar area and anteriorly, and 20% on the heels, the majority being situated on pressure points. this series only one has been encountered on the area afforded by the longitudinal arch.

Treatment was carried out entirely by medical auxiliary chiropodists in the municip clinic. The standard treatment, adopted in most was as follows:

(1) Swabbing of the whole foot with surgical spirit.

(2) Removal of any mass of callous tissue to facil action of the acid to be applied.

(3) The area surrounding the wart is painted with or with tinct. benzoin. co. to prevent irritation by plaster.

(4) The wart is isolated with a stockinette cover in a small hole is cut about the size of the wart.

(5) 'Chlorosal' (salicylic acid 60%, chloral hydrate applied through the hole in the stockinette, and a cut so that no direct pressure results, is placed wart.

(6) The whole dressing is finally enclosed in st and secured with adhesive strapping.

The patient is instructed to keep the wart to return in 7–14 days, when the treatment is The above-mentioned procedure takes 6–8 min. for wart. On the average three treatments only are but two subsequent visits at monthly int insisted on for checking the results. Monochl acid and silver nitrate are occasionally used in chlorosal. This treatment is painless in most and where pain is experienced it passes off very The average number of attendances before final di was 5·6, and the average number of treatments 3 The results of treatment were assessed in 50 c who had completed their treatment not less than months previously. All these children were tak

BEDS FOR PULMONARY TUBERCULOSIS

Sir,—The correspondence on this vital subject initiated Dr. Bentley's article of May 8 and exacerbated by . Stradling's letter (Aug. 21) has caused Dr. Snell and colleagues (Sept. 4) to touch on the really important l thorny topic of the direct control of beds.

They say: “We do not think the bed position would greatly improved by giving the chest-clinic physician -ect control of all beds.” This statement should, I l, be approved if the sanatorium is to play its proper e in the tuberculosis scheme. The sanatorium physician ould have a large part in the allocation of cases to the atorium under his jurisdiction, if not the final word their admission. This is not so today. In giving this nsibility to the sanatorium physician three ends d be served: (1) it would help to bridge the gap een the clinic and hospital physicians; (2) it would r to making the central waiting-list less “central”; (3) it would ensure that the truly treatable case was at an early date by the physician who is to be in harge of treatment.

Every sanatorium is as good as its medical super- ident,” and the enhancement of the authority of the icians of these institutions would eventually rid the torium of much of its chronic and untreatable ilation to the benefit of the early case on which alone best results of treatment, especially chemotherapy, be realised.

SUPERNUMERARY NIPPLES

ir.—I have read with interest the letters following Harper's paper of June 12 on supernumerary nipples onnexion with neurosis, but I should like to know ther there are any figures for the occurrence of extra ples in the two sexes. I have never seen supernumerary ples in a woman, but have seen quite a number in . Whether this is merely a coincidence I do not w, but I have come to regard this abnormality as nmoner in men than in women.

anyuki, Kenya Colony. G. DUNDERDALE.

his letter has been shown to Dr. Harper, who replies follows.

r. Dunderdale, in expressing his belief that poly- lia is commoner in men than in women, is in line with classical opinions of Leichtenstern[1] and Bruce.[2] Leichtenstern's own 13 cases, 9 were in men, and n women. However, he extracted from the literature cases, of which 70 were in women, nearly all of whom e pregnant, and only 22 in men.

Bruce records 24 cases, of which 19 were males (9·1% 207 males examined) and 5 females (4·8% of 104 nales examined). Both observers recognise the following rces of error: (1) the variation in characteristics of groups examined; (2) the greater ease of detection of tiges at routine examination in male subjects, ighting the scale in their favour; and (3) the special tention directed to the breasts in pregnant women, fluencing the scale on behalf of the female sex.

Certain racial differences appear to exist. Among panese women 5·19–6%, and among Japanese men 68–2·03% are recorded by Iwai. For Chinese men the ure given by Takeya[3] is 3·6%.

de Cholnoky[4] has dealt with the phylogenetic signi- ance of supernumerary breasts, both on and off the nbryonic milk line, and believes that polythelia occurs equal numbers of persons in the two sexes, a conser- tive estimate being from 1 to 2% of the population. e draws attention to published figures giving the idence as high as from 14 to 23·3% of the popula- m, but believes his own estimate to be more exact. e has collected from the literature 64 cases of breasts atypical positions; 37 of these were in women and in men.

My own cases of supernumerary nipples in the nbryonic milk line include 72 men and 100 women. However, the preponderance of females at outpatient clinics and surgeries makes these figures of general interest only as regards sex incidence. The paper by Matthews and Baxter[5] deals with the much rarer occurrence of polythelia in subhuman primates. The small number of cases hitherto described include both males and females.

Should we require a reminder of the difficulties of statistical certainty in this field, we may remember these words from Darwin's “Origin of Species”:[6]

> “Rudimentary organs may be compared with the letters in a word, still retained in the spelling, but become useless in the pronunciation, but which serve as a clue for its derivation.”

Barnstaple. RICHARD HARPER.

DIRECT REDUCTION OF FORWARD DISLOCATION OF THE MANDIBLE

Sir,—Though forward dislocation of the lower jaw is not common it is by no means rare, and every general practitioner or casualty officer is likely to be called on to treat it. In this type of dislocation the condyle and the articular disc slip forward into the zygomatic fossa when the mouth is opened too widely. The usual textbook method of reduction is as follows:

> The patient sits in a chair, and the surgeon stands in front of him, introduces his well-protected thumbs into the patient's mouth, exerts pressure with the thumbs on the lower molar teeth downwards and backwards to disengage the condyle from the zygomatic fossa, and then with his fingers raises the chin.

In most cases this method is successful and can be performed without anæsthesia. But sometimes the reduction is not easy and the patient suffers agonising pain at each renewed attempt.

The following simple and effective method of reduction, so far as I know, is neither described nor taught in medical schools either in Great Britain or on the Continent. It does not call for anæsthesia, can be executed in half a minute, and is practically painless. The posture of the patient is irrelevant, and the protection of the surgeon's fingers unnecessary. The surgeon introduces his index finger (in bilateral dislocation both index fingers) into the vestibule of the mouth—i.e., between the cheek and the mandible—as far as a point $1^{1}/_{4}$ in. above the last lower molar, palpates the coronary process of the mandible (easy to palpate if the jaw is dislocated, but not when the jaw is in its normal position), and presses gently with the tip of his finger on the coronary process backwards and downwards, whereupon the condyle slips back into the mandibular fossa with ease.

This direct method has never yet failed me though I always used it in difficult cases where I was called when the textbook method had failed. Now that the casualty officers have learnt the simple trick they find it just as satisfactory as I have found it.

New York. G. MASCHANZKER.

SIXTY YEARS OF MEDICAL DEFENCE

Sir,—Your annotation on Aug. 14 put forward some cogent reasons for amalgamation of the two rival defence organisations. It appears that a strong case can be made for “pooling the experience and resources of the existing bodies” at the present time. In addition to the broad issues of policy and finance mentioned in this article there is a further point which may be worth consideration.

My principal and I are severally indebted for quiet sleep during an aggregate of some thirty years to the security afforded by our respective membership of the Medical Protection Society and the Medical Defence Union. Our reasons for joining the rival camps go no further than the individual predilections of the forensic-medicine lecturers at our different medical schools: neither of us is aware of advantages to commend either body in preference to its rival. But being together faced with allegations against our professional conduct, unfounded though we both believe them to be, it seems inefficient as well as irksome to be obliged to lay our common problem separately before two advisory

When one is sitting still and an attack starts to come on, it may be lessened and sometimes kept off by working the muscles. One may get up and walk about or contract and relax the muscles above the knees. This is not always successful with a very bad attack.

In, I think, 1911 I returned from abroad after having had typhoid fever. On my arrival at an English port I had an attack of the continuing paralysis which rendered me almost helpless for three weeks. I think the immediate cause of this particular attack was the strong sea air. We went inland and my father suggested that I should take cod-liver oil to pick me up. After a little time I noticed that almost all attacks of the paralysis had ceased, and my mother and brother therefore started to take the oil and with the same result. The oil is not, however, a cure, but a "keep off" and has to be taken continuously. It takes full effect in about a fortnight, and after it is left off the attacks are in evidence as usual in about the same time. The amount to be taken varies with the amount of exercise one takes and with other circumstances; but, roughly speaking, about 1 pint a week is enough. Less will help, but minor or medium attacks will probably occur. The oil enables one to live a more or less normal life, though of course not a very strenuous one. The continuing attacks never occur when one is taking the oil. When starting to take it, they are the first to go; and they are the last to reappear when it has been left off. In my experience only the pure oil does any good.

G. D. H.

*** Farquhar Buzzard's article provided the first record in Great Britain of periodic paralysis affecting more than one member of a family. In the same year Dr. H. D. Singer had reported a sporadic case in the summer number of *Brain*.—ED. L.

THE CROSSBOW OUTLET PELVIMETER

SIR,—I was interested in the instrument described by Mr. Morris (July 24, p. 139) for the obstetrical evaluation of the pubic arch. Two years ago I devised an instrument for measuring the anterior and posterior sagittal diameters of the outlet and have since used it on some eighty patients with pelvic contraction, who were sent for X-ray pelvimetry.

This outlet pelvimeter is of a crossbow pattern (fig. 1) and is made of brass, which may be sterilised by boiling and kept in 'Dettol' solution. It has three component parts—a half-circle of $3^3/_4$ in. diameter and with a transverse axial bar (which represents a hemi-section of the fully flexed and unmoulded, full-term fœtal head), a T-connecting piece, and a measuring rod. The transverse axial bar of the half-circle is $3^3/_4$ in. long, equivalent to the biparietal diameter of the fœtal head, and is incomplete in the middle to allow the measuring rod to pass as required; and two eminences are raised on the bar which appose the fitted connecting T-piece. The brass circumference is $^1/_{24}$ in. thick and $^1/_2$ in. wide, and has an opening at its apex through which the measuring rod passes. The T-piece is hollow and receives the cut ends of the transverse bar as far as its eminences, and through its vertical part, which is 1 in. long measured from the centre of the transverse axis, passes the measuring rod. A central screw can be tightened to fix the measuring rod.

The measuring rod is 8 in. long and has a curved sacral end to enable the posterior sagittal diameter to be measured; its scale begins at the straight end and finishes at the curve of the rod $1^1/_2$ in. from its tip. The measurement of the anterior sagittal diameter begins at the straight end of the rod, and is read down to the vertical bar of the T-piece, which adds 1 in. to the estimated length.

A measurement is made with the patient in the lateral position with both thighs fully and flexed. The circumference of the pelvimeter ap the pubic arch from behind and is gently pressed against its rami. The measuring rod is then through the brass rim to the apex of the pubic arch distance from the symphysis to the transverse read off. This is considered to be the true sagittal diameter of the pelvic outlet which is measured, since the available transverse diameter outlet occurs where the head will pivot and is positioned by the crossbar and may be in front of or behind the ischial tuberosities according to the width of the pubic arch.

Fig. 2 shows the pelvimeter in position in an average-sized pubic arch, and the anterior sagittal diameter measures 2·6 in.

Fig. 3 shows an anterior sagittal measurement of 3·6 in. in a pelvis with a narrow pubic arch. From an estimation of the anterior sagittal diameter in eighty cases it has been found that measurements above 2·8 in. indicate a narrow pubic arch, and the greater the measurement the narrower the arch.

Fig. 1

Without the pelvimeter being moved the posterior sagittal diameter is measured. The measuring rod is drawn sufficiently for the T-piece to pivot on transverse axial bar, and the curved end is touch the outer aspect of the sacro-coccygeal which has been located by moving the coccyx w fingers, one of which palpates from inside the This measurement has been shown to average and to be influenced by the length of the antero diameter of the outlet and the narrowness of the arch. In fig. 4 the posterior sagittal diameter 2·8 in. and in fig. 5 1·4 in.

Queen Charlotte's Maternity Hospital, London.

Figs. 2–5.

doubt examiners take these factors into account; he psychological effect of being deliberately misled ced with a patient who cannot coöperate is devas- g. From my experience I would say that the ination is an extremely poor method of differentia- those who have a wide knowledge of clinical medicine those who have not; and that the conditions are dically different from those obtaining in an out- nt department or ward that not even the most rienced examiner can detect which candidates are to excel in these fields. The art of taking a history least as important as the ability to elicit physical , and the former is scarcely tested at all in this ination.

myself lay no claim to a particularly detailed ledge of general medicine; I took the examina- in order to specialise; however, several of my ds whose experience and knowledge in this field far ed my own, and whose advice I often seek, have so been unable to pass the examination. I would e with "Would-be-Member" (Aug. 21) that the solution is to increase the time spent on the clinical ion, and if possible to see the candidate at work n outpatient department. This would no doubt e the examination even more tedious and expensive, it might ensure that this overrated title of M.R.C.P. conferred only on those who deserved it.

FORTUNATUS.

URINARY INCONTINENCE IN THE AGED

R,—Dr. Wilson's article of Sept. 4 is particularly able for its emphasis on training the bladder as one s a disabled limb or defective eye or even the actions peech.

stometry is still used far too little in both neuro- al and urological investigations. Some months ago ew attention to the value of this procedure in the ssment of children with enuresis.[1] Doctors today far too ready to send to the psychiatrist either the d or the adult who happens to be antisocial in that dder control is defective. Let us see that we call he psychiatrist as an aid in functional disorders and merely to rid ourselves of the tedium and burden ll investigations on an organic level.

ndon, W.1.　D. F. ELLISON NASH.

BOVINE PLASMA

R,—With reference to the articles on this subject h have appeared in your columns during the past years,[2] we should like to inform you of the results ined in our laboratory.

enatured calf plasma (D.C.P.) prepared by us exactly escribed by Massons (as well as a sample of D.C.P. pared by Massons himself) has been found to possess ng anaphylactogenic properties. In experiments guineapigs it was found that, while shock-provoking er is completely absent, the sensitising power is still ent, although the lethal dose of fresh bovine plasma guineapigs sensitised with D.C.P. is twice that necessary hock the controls sensitised with fresh plasma. The rval between the two injections was 45 days. In tice this would preclude the use of a preparation of se plasma but not of bovine plasma, since fresh ine plasma is not commonly used.

ven so it is of interest to record the disagreement ween our results and those obtained by earlier kers; this disparity would appear to be accounted by the technique employed by these workers, which obviously inadequate to demonstrate the sensitising shocking properties of plasma. In fact the latent iod increases with increase in the sensitising dose of igen; and it is very long for doses greater than 0·2 ml. of serum or plasma.

ACUTE BENIGN DRY PLEURISY

SIR,—In the interesting article by Dr. Gray and Dr. Carter (Aug. 14) I noticed that this condition was referred to as Bornholm disease. Actually, the condition was first described in Telemark, Norway, by Dr. A. Daa in 1872, and it was later called Bamble disease, as the first cases were reported from a district of that name. The same condition was observed in Iceland by Finsen in 1856 and 1863, but his findings were not published until 1874. In the U.S.A. the disease was observed and described by Dabney in 1888. Syvest's splendid treatise on this subject was published in 1933.

Porsgrunn, Norway.　A. SCHRUMPF.

HANDLING OF FOOD

SIR,—The supply of pure food is, in theory, ensured by legislation; but failure to store and prepare it in cleanliness and freedom from contamination until it reaches the consumer is so common that one is tempted to suspect the absence of any legislation by which these measures may be enforced.

Similarly, the cleansing of cups, glasses, knives, forks, and other utensils used in the preparation and serving of food and drink is commonly carried out in so perfunctory and careless a manner that there is a real risk of infection. It is not that the local sanitary authorities are not empowered to use compulsion in these matters and in the maintenance of hygienic conditions in kitchens and larders where food is stored and handled; they are. Endeavours have been made to secure these ends, as Dr. F. A. Belam, medical officer of health for Guildford, has so aptly put it, "by persuasion," but people will always be found on whom persuasion has little effect.

It seems to me that the time has come for reviewing the whole of the legislation governing this subject and tightening it up. The duties of medical officers of health are so multifarious in these days that frequent inspections of premises may be difficult. A weak link in the chain from producer to consumer could easily be responsible for serious disease. Cases of food-poisoning are becoming far too frequent, largely because so many people now feed out in public restaurants who never did so before. Recent episodes which have occurred within my own experience will give point to my remarks:

A patient of mine went to her butcher's for the weekly meat ration. She described the shop as "full of bluebottles," which were flying about and settling on joints of meat in the window. While the butcher was conversing with another customer she noticed that his hand was slowly stroking a piece of meat. To her horror she saw that it was covered with maggots which the butcher was surreptitiously—as he thought—sweeping off with his hand.

A butcher, whom I knew to be suffering from a septic discharging sore on a finger, was handling meat with a bloodstained piece of rag round the finger. I asked him whether he thought it was a very good thing to do, not only for his own safety but for that of the meat. "Oh, the cooking will kill all the germs," he replied.

I saw a baker's roundsman taking loaves from his van and putting them in a basket for delivery to customers. He dropped one on the road, which was wet after a recent shower. He picked it up, looked at it, wiped it on the side of his trousers, and put it in the basket for delivery with the rest.

I was called to see a patient who had advanced carcinoma of the tongue and secondary involvement of glands in the neck which were on the point of breaking down. He had refused operation and hospital treatment. The stench was so horrible that I smelt it directly the front door was opened. The whole house reeked of it, and in his room, where the windows were shut, it was almost unendurable. He was also a chronic alcoholic—for which I did not blame him—and was in the habit of going out in the evening to two public-houses and returning home intoxicated after closing time. It was the practice at these public-houses to clean the tumblers by swishing them round in a receptacle of cold water under the counter and wiping them. They looked quite clean.

My wife and I went to a well-known London restaurant for luncheon at the most crowded time of the day. There were no tumblers on the table and I asked the waitress to bring some. She put them on the table dripping wet, and I noticed that the rim of mine was greasy and had traces bodies, notwithstanding their equal competence and trustworthiness.

This difficulty of two professional associates together faced with allegations on the same ground by the same patient cannot be unique. Would not the respective councils of the two bodies in which our confidence is placed do well to consider combining not only resources but advisory offices? That this would benefit the members of each by pooling experience and economising administration, is apparent. It would also save the feelings and time of any who may find themselves in the unfortunate position of my senior colleague or myself.

UNIONIST.

THE INTENDING EMIGRANT

SIR,—A peripatetic correspondent of Aug. 21 comments on the lack of preparation of intending emigrants. An Empire information bureau has been established by the Royal Empire Society to answer questions *inter alia* on living conditions in our Empire territories. Information on the very points mentioned—housing, clothes, cars, education—is given freely to all inquirers whether by post or in person. A series of information papers on living conditions has been prepared for seventeen Colonial territories; these can be consulted in many public libraries or can be obtained on application (enclosing postage) to this address.

ARCHER CUST
Secretary-General, Royal Empire Society.
Northumberland Avenue, London, W.C.2.

ASSOCIATION OF WHOLE-TIME SALARIED SPECIALISTS

SIR,—Further to the notice in your issue of July 17, (p. 127), the members of this association (formerly the Association of Municipal Specialists) feel that much was done in the past by the old association to secure for them adequate representation on important medicopolitical committees, and valuable advice has been given on salaries, legal problems, &c. This work will be carried on by the new association, whose four principal objects are as follows: (1) to improve the practice of medicine in all its branches; (2) to improve the status and promote the general interest of whole-time salaried specialists; (3) to provide opportunity for discussion on matters of professional interest and policy; and (4) to promote good relations between all specialists.

All whole-time salaried specialists are eligible for membership, and I shall be pleased to supply further information on request.

RUFUS C. THOMAS
Honorary Secretary.
45, Lincoln's Inn Fields, London, W.C.2.

HOSPITAL LIBRARIES

SIR,—Your annotation last week is a welcome indication to library workers of the increased value placed on the services which they administer. Your advocacy should encourage the new hospital authorities to provide adequate libraries for all kinds of readers—doctors, nurses, and patients—who look to them for books, and to realise the need, which you emphasise, for trained library staff. But your suggestion that the scientific and recreational libraries in hospitals should be combined is open to question. A committee appointed by the Library Association to consider the training of hospital librarians resolved in 1945 that these two categories of hospital library are incompatible. As you point out, it has been proved that recreational libraries are often best administered by the local public library. But the scientific literature required by the professional staff and auxiliaries, by the practitioners of the district, and by medical students must be dealt with, as the Library Association's committee agreed, by a distinct and specially trained staff.

W. R. LEFANU
Librarian,
Royal College of Surgeons of England.
London, W.C.2.

SIR,—The recognition in your annotation last week of the contributions of voluntary work in libraries for patients, is most encouraging to members of the Guild of Hospital Librarians. Our special aim is to contribute to the welfare of patients by loyal attachment to the hospital, and by increasing our own efficiency. publication of a quarterly periodical, the *Book T* forms a bond of union and interchange of More could be done by the guild with an increase membership, and we should welcome the coöperatio your readers in attaining that object.

MARY BUCHANAN
Chairman of the Guild Hospital Librarians.
102, Carrington House, Hertford Street, London, W.1.

THE DEAF CHILD

SIR,—In the article on this subject (June 12) in disabilities series I was surprised to see no mentk the school medical officer. Surely he is the man to parents on the track of obtaining help in such a Under the new Act the child does not need to be the books of a school to be eligible. Furthermore, writer's remarks about war-time London were strictly accurate. There was at least one school for deaf open; its name escapes me at the moment, it was situated just to the south of Victoria st school so noisy owing to the proximity of the trains only deaf children could possibly use it.

W. NORMAN TAY
Fort Hare, Cape Province, South Africa.

SHOULDER PAIN FROM PEPTIC PERFORA

SIR,—The occurrence of shoulder pain in peptic tion is widely recognised as evidence of irritation. The pain is generally felt on the right but may be bilateral, in which latter event it is that anterior perforation is causing irritation of median portion of the diaphragm.[1]

I recently operated upon a man for perforation gastric ulcer into the lesser sac. The usual signs symptoms were present, but, in addition, he had the *left* shoulder commencing at the same time generalised abdominal pain; this was presumably irritation of the left half of the diaphragm.

Most anatomy textbooks indicate only a relationship of the lesser sac to the crura of the phragm—chiefly of the upper recess with the right. Crymble,[2] in *Quain's Anatomy*, deals in more with the anatomy and variations of the lesser sac. bursa omenti minoris communicates on the left the bursa omenti majoris through the variab foramen bursæ omenti majoris. This latter itself subdivided into an upper and lower portion by plica cardiaca. It is this upper part which comes relationship with the left crus and lower posterior p of the diaphragm.

Lesser-sac perforations are uncommon, and I hesitate to draw conclusions on observation of only patient; but it would be interesting to know if surgeons have noticed left-sided shoulder pain in cases.

C. PATRICK
St. Mary's Hospital, London, W.2.

M.R.C.P. EXAMINATION

SIR,—I have read the correspondence on this sub with interest, since I passed only at the fifth att and I should like to supplement the criticisms of correspondents.

At my first attempt, in which I survived the part, I was told to look at a "short case" which examiner informed me was cardiological. It pro be one of obstruction of the vena cava secondary carcinoma of the lung: the patient certainly had which might be mistaken for cardiac failure, but examiner agreed that there was nothing wrong the heart, over which I had naturally puzzled for time. On another occasion I was given a man G.P.I. who refused to answer any questions wha On a third I was shown a man with syringomyelia was stone deaf: if one pricked him with a pin he say "sharp" or "blunt," but he had no other versation. The time that I passed, I had perfe straightforward cases, none of the patients be psychotic or deaf or otherwise debarred from giving history.

Obituary

THOMAS GWYNNE MAITLAND

M.A., M.D., B.SC. EDIN., D.PHIL. MANC.

T. G. Maitland, who died on Aug. 10, was from ntil his retirement in 1946 medical superintendent Cunard White Star Line.

ı at Merthyr Tydfil in 1875 he was educated at sity College School, London, and at the universities inburgh, Manchester, and Paris. In 1907 he ted in medicine at Edinburgh, and he was awarded tion for his M.D. thesis the following year. He ok an honours course in philosophy at Manchester, ding to the D.PHIL. in 1911. After holding a it appointment at the Brompton Hospital, he e demonstrator of physiology at Manchester, ter lecturer in the same subject at the universities les, Birmingham, and Manchester. For a time, ne was honorary physician at the Walsall and t Hospital. His literary interests led him to he *Manchester Medical Gazette* and to become tor of the *Midland Medical Review*. During the 18 war he was director of the typhus colony at je in Serbia, and he was made an honorary colonel in the Serbian Army.

1920 he joined the Cunard Company and for six he acted as medical officer in one or other of the hips which were laid down and commissioned to e those lost in the war. They were years which big development in winter cruising, and Maitland o meet the new problems which arose in mercantile ine as ships designed for the North Atlantic trips to be adapted for long voyages in semitropical s. In 1926, he succeeded Dr. David Morgan as d medical superintendent, with the task of supervis- he medical and nursing work of the ships, the al aspects of living on board ship, and the equip- of ships' surgeries and dispensaries and hospital lations.

th the requisitioning of ships for transport and other ork in 1939, a host of new problems had to be met. laitland's help was sought far beyond the confines own organisation. Nothing in the medical aspect at sea was beyond the range of his interest; he d out a good deal of research into seasickness, ample, and he took a large share in the establish- of the radiomedical service, whereby ships with octor aboard obtain medical advice by wireless.

he retired from the Cunard White Star Line, it ot long before he felt that he would like to go to gain. He made a long voyage, as ship's doctor, e Far East but found the heat too much for him. me back knowing that the voyage had not been a ss, and his friends realised that it had taken a great out of him.

laitland always said," writes R. C., "that he was uly a philosopher; but he was a very human one, is interest in workers on board ship and especially e docks led him with quiet but terrier-like determina- to insist that adequate first-aid centres and accident itals were established right in the heart of these erous occupations. The Merseyside and Birmingham dent Centres owe much to his persistence. Perhaps than any other man he improved immeasurably tatus and quality of ship's doctoring. Working in ackground, he brought his intelligence and keenness le support of industrial medicine, for his interests far beyond the sphere of his own job. He quietly raged young consultants to do a voyage across the tic and back, knowing that on a long-term view uld benefit both them and the mercantile medical e. Often he would gather together a little group ctors of diverse interests at a lunch party on one ships in dock. They were memorable affairs, and on all sorts of medical and other matters waxed nd furious. In his later years at least he was a oking man, with a limp from a painful arthritis e disability also of a duodenal ulcer, but these things ot crush his spirit. Meeting him, you were aware e that here was a remarkable personality, a man iet distinction and fineness of quality, a man moreover who delighted to pull your leg, who loved good talk and company, and who enjoyed both subtle wit and happy fun. With his death some of the warmth has gone out of life."

ANDREW RADBURNE FULLER

M.R.C.S., D.P.H.

Dr. A. R. Fuller, of Perranporth, Cornwall, who died on July 19 at the age of 55, was the elder son of Dr. Andrew Fuller, chief medical officer for England and Wales under the Local Government Board. He was educated at Leighton Park School and St. Mary's Hospital, at both of which he won open scholarships. In September, 1914, he went to France with the Red Cross as a medical orderly, returning in 1915 to finish his medical course. Immediately after qualifying in 1916, he was commissioned in the R.A.M.C. and posted as a battalion medical officer to a division in the Battle of the Somme. Early in 1917 he was sent home to spend many weary months in hospital and was invalided out in 1920. In the same year he took his D.P.H., and he joined his father in practice at Perranporth in 1921 where he remained until his death.

"Fuller," a colleague writes, "will long be remembered by all in Perranporth and the surrounding district for his medical ability and devotion to his work, which he combined with a sincere and unselfish love of his fellow men. He upheld the finest traditions of the profession. A keen athlete, he was a first-class cricketer and tennis player, holding the Cornish singles championship for three successive years and also playing first couple for the county."

Dr. Fuller married in 1925 Elizabeth Mary, younger daughter of Dr. Peter Ingram, of London, and he leaves his wife with a son and a daughter. A twin son died in 1943.

Appointments

DICKS, H. V., M.A., M.D. Camb., F.R.C.P.: senior psychiatrist, Tavistock Clinic, London.

GOODDY, W. W., M.D. Lond., M.R.C.P.: registrar, National Hospital for Nervous Diseases, London.

GRACIE, A. P., M.B. Edin., F.R.C.S.E.: accident officer, Salford Royal Hospital.

ROSS, M. S., M.R.C.S.: clinical pathologist, Queen Mary's Hospital for the East End, London.

WILDMAN, J. H., M.R.C.S., D.P.H.: M.O.H., East Herts combined sanitary district.

Colonial Service:

AZZOPARDI, E., M.D.: M.O., Federation of Malaya.
BARTLEY, A. H., M.R.C.S.: M.O., British Honduras.

Births, Marriages, and Deaths

BIRTHS

CUTTS.—On Sept. 1, in London, the wife of Dr. Geoffrey Cutts—a daughter.

FOX.—On Aug. 22, in London, the wife of Dr. J. P. Fox—a son.

ROCHE.—On Aug. 29, at Leeds, the wife of Dr. J. Roche—a son.

SHILLINGFORD.—On Aug. 31, in London, the wife of Dr. J. P. Shillingford—a son.

MARRIAGES

SEARS—CONN.—On Sept. 4, at St. Andrews, Harold Trevor Newton Sears, M.R.C.P., to Janet Sorley Conn, M.B.

DEATHS

FRENCH.—On Aug. 29, at Nairobi, Stanley Gay French, M.B. Lond., F.R.C.S., surgeon lieut.-commander, R.N., aged 40.

MARRIOTT.—On Aug. 30, Francis Keene Marriott, M.C., M.R.C.S.

MURRAY.—On Aug. 9, at Dornoch, Sutherland, David Alexander Murray, M.B. Edin., aged 50.

PATERSON.—On Aug. 28, in London, Arthur Robert Paterson, M.D. Brux., major I.M.S. retd., aged 88.

RASHLEIGH.—On Aug. 29, at St. Peter's-in-Thanet, Hugh George Rashleigh, M.R.C.S., aged 72.

WHEATON.—On Sept. 5, Samuel Walton Wheaton, M.D. Lond., F.R.C.P., D.P.H., aged 86.

WIGMORE.—On Aug. 29, at Minehead, A. J. O. Wigmore, M.B. Brist., squadron leader, R.A.F. retd., aged 63.

of lipstick. When I called her attention to it she wiped them hurriedly on what appeared to be a damp and dirty table napkin and replaced them on the table as "clean."

One has only to think of all the conditions in which infection is carried in the mouth—oral sepsis, diphtheria, syphilis, and the rest—and of common methods of cleansing drinking and eating utensils to realise the need for urgent reform. The answer appears to be threefold: legislation, education, and equipment. A study of the meticulously hygienic methods evolved and practised in the United States would be well worth while.

Brookwood, Surrey. H. M. STANLEY TURNER.

Public Health

NIGHTSHADE POISONING

Two outbreaks of nightshade poisoning have lately been observed in the south of England—one due to *Atropa belladonna* (deadly nightshade) and the other to *Solanum dulcamara* (woody nightshade).

DEADLY NIGHTSHADE

On the afternoon of Sept. 1 a party of children went blackberrying, at Milton, Portsmouth, on a plot of waste ground where, entwined among the stems of two large blackberry bushes, were several deadly nightshade plants, also bearing large black berries. The next day five of the children were admitted to hospital with acute belladonna poisoning.

The first three children to be admitted were two sisters and a brother, aged 7 and 8, who were said by their mother to have returned home at about 5 P.M. on the previous afternoon. Complaining of tiredness and thirst, they refused tea, but appeared normal; and two hours later, at 7 P.M., they went to bed and slept. At 9 P.M. they were awake, and in rambling speech complained of being unable to see. One child "kept falling about the room," and their mother thought that all three had a high temperature. On admission to hospital the next morning, all three were very restless, constantly executing purposeless movements, twisting about, grimacing, and plucking at the bedclothes. Two were talkative and obviously hallucinated, and their speech was a little slurred; the third, who lay with her head buried in the pillow fiercely resisting interference, seemed to have some photophobia. All three had hot dry skins and a pronounced malar flush; the lips were dry and fissured. The pupils were widely dilated and unresponsive to light; all tendon reflexes were brisk. The pulse-rate in each case was 120–130 per min.; the temperature was normal and the respiratory-rate was not increased. The highest blood-pressure was in the boy, in whom it was 138/80 mm. Hg.

Later the same morning a fourth child was admitted. After returning from the blackberrying expedition on the previous day he had had a large tea at 6 P.M.; at 9 P.M. he had gone to bed, apparently well. At 2.30 A.M. he was found struggling with his elder brother; he spoke incoherently, seemed not to recognise his parents, and kept picking imaginary objects off the bedclothes. At 4 A.M. he was given morphine by his doctor, and remained drowsy until admission at 1.30 P.M.

Soon after this, a fifth child, aged 6 years, was admitted. On his return from blackberrying he had had supper at 7.30 P.M. and gone to bed. During the night he was awake and twice vomited. At 6.30 A.M. both parents went out, leaving him in charge of an elder sister, who had summoned help at 12.30 P.M. because he was talking strangely.

Treatment.—On admission gastric lavage was carried out on all five children, first with plain water, then with potassium permanganate gr. 10 to the pint. This induced vomiting. Among the first three cases, over 30 berries were recovered from the boy's vomitus and nearly as many from that of each of his sisters. The berries in the gastric contents closely resembled raisins, but the seeds were smaller and darker than raisin "stones." No berries were recovered from the stomachs of the last two admissions. From rectal wash-outs no seeds or berries were recovered. Four hours later gastric lavage repeated and in the first three cases several more were obtained. In each case a solution conta magnesium sulphate gr. 90 was introduced into stomach.

Progress.—Late on the evening of Sept. 2 the child condition was not appreciably changed; all were extremely restless and hallucinated, with persiste high pulse-rates. All were incontinent; but there no evidence of urinary retention. During the night slept sporadically, and by 9.30 the next morning (Se all except the boy *in the first group* were quieter and f coöperative, though suspicious and resentful of ex tion. They complained of great thirst, and two of of severe frontal headache; malar flush was still nounced, but the pupils were smaller and reacted sl to light. The saline aperient was repeated; and evening large numbers of seeds and berry skins were being passed by each of the first three cases. Of t three, the boy is estimated to have eaten at least berries and his two sisters 20–30 each. The physic charge of these patients adds: "Why no berries or should be recovered from the other children, w *symptoms were no less severe, is a mystery.*" important features in these cases, he suggests, a follows:

1. The long time between the ingestion of the berries the appearance of symptoms.
2. The prominence of hallucination and the abse fever or respiratory depression.
3. The significance of "raisins" in the vomit (unlike deadly nightshade berries), which might not have appreciated in the absence of a history that berries had eaten.
4. The *necessity in such cases as these* of administer emetic; many of the berries would have blocked the stomach-tube.

WOODY NIGHTSHADE

A girl, aged 9 years, was admitted to hospi Canterbury on Aug. 13, with abdominal pain, vomiting, and distressed breathing. She had been habit of eating berries from hedges near her home, had last done this 3 days before admission. The foll day she had felt unwell but had improved. She vomited "coffee-ground" material four times duri five hours before admission; there was no diar She looked exhausted and anxious; her pulse-rate 140 per min., and her skin was pale and dry. Her p were of normal size and reacted to light. Treat included gastric lavage, soap-and-water enemas, n amide, and latterly oxygen; fluids were given by m and per rectum. After 24 hours her condition, which improved somewhat, deteriorated again, with incre weakness, cyanosis, and feeble respiration. She died the morning of Sept. 15.

At necropsy the principal finding was acute infla tion of the mucosa of stomach and small int decreasing in intensity towards the distal end. An of the liver revealed the presence of solanine.

INICAL RESEARCH IN THE EDUCATION OF THE SPECIALIST *

W. MELVILLE ARNOTT
T.D., M.D., B.Sc. Edin., F.R.C.P.E., M.R.C.P.
ILLIAM WITHERING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF BIRMINGHAM

NE hears much these days about research; indeed in tion to clinical medicine it almost threatens to become one of contention. Clearly, there is a wide difference he interpretation of the term. To some research is to be synonymous with the paraphernalia of the ratory and with the esoteric techniques of modern nistry and physics; to others it is the production papers; and to all too few it is essentially an llectual approach.

ne of the most attractive and stimulating articles he appointment I hold is that which charges me the personal conduct, organisation, and direction search. The endeavour to discharge this obligation ssitates much thought and experiment directed to rtaining the optimum methods of design and prose- on of investigation. These are pressing matters h face many; feasible solutions are vital to the ess not only of the many whole-time university cal departments that are being established but also e whole future of clinical practice.

the various recent memoranda on specialist training have come from the Royal Colleges there has been rm insistence on a period of a year or so of the ears of apprenticeship being spent in work in the ed basic sciences. There is a tendency to imply this year should be non-clinical and should be in the departments of anatomy, physiology, stry, &c. Though these departments provide able training, it should be possible to provide equally and perhaps even better opportunity for training scientific method in clinical departments. Indeed listinction will, I feel sure, become increasingly ous as the preclinical and clinical departments of nedical schools find increasing community of effort ching, research, and clinical practice.

ere has unfortunately been in the past a measure sociation between those in laboratory work and in clinical practice, which has been harmful to groups and has been due to faults on both sides. non-clinical scientist has sometimes believed that linical colleague is not only incapable of but even emptuous of the scientific method, while the clinician is turn has sometimes felt that the "lab man" is l to the problems of clinical practice and insensitive he humanitarian appeal. Such schisms are closing, medicine, in Britain at least, is entering an era ntegration and coöperation which will favour new overy and rational practice.

STATISTICS

hat contribution should the study of research hods, or the actual prosecution of research, make to training of the specialist in medicine? Obviously he allotted time it can give comparatively little by of detailed technical knowledge. Its main purpose t be to develop the habit of mind which is attuned he challenge of the unknown, is continually seeking mprove the precision of observation, and in the cise of diagnosis or the assessment of therapeutic t places reliance on phenomena in inverse proportion heir inherent variability. Whatever else is learnt edical training, a sound appreciation of the value e quantitative approach is essential. The evolution of every branch of science has been through the descriptive stage to the maturity of the increasingly precise application of the quantitative language of mathematics. Biology, and particularly clinical biology, has presented peculiar resistance to this evolutionary process, but this is being steadily overcome. One has only to consider the development of clinical chemistry and the recent rapid development of quantitative methods in the clinical physiology of the cardiovascular system to realise the increasing application of physical and chemical techniques to human function and dysfunction.

The most important forward influence is the steady penetration into clinical practice of the principles of statistical thought. The intelligent practice of medicine, and especially investigative medicine, is inescapably bound up with degrees of probability and improbability based on accumulations of numerical data. It is not so long since the techniques of statistical analysis were reserved for the vital statistics of large populations and were the exclusive perquisites of the Registrar-General, the medical officer of health, and the insurance actuary. However, the brilliant researches of R. A. Fisher and his colleagues have developed the mathematical treatment of small groups of observations, and the methods evolved at the Agricultural Research Station at Rothamsted are eminently suited to the numerical observations of the ward and of general practice. Most of the reputable medical journals now require numerical data submitted to them to show evidence of quantitative assessment of degrees of significance or of correlation, and an increasing number of valuable contributions have only been possible by the application of the more advanced methods of the analysis of variance, &c. Unfortunately it is still possbile to cull from current medical literature numerous examples of false conclusions based on the uncritical assembly of quantitative observations.

The education of the doctor, be he a specialist in clinical practice or a specialist in clinical research, requires not so much the acquisition of mathematical techniques as the development of a sense of the variability of biological measurement and of the existence of methods of measuring, controlling, and explaining this variability. The modern medical teaching and research organisation has its statistical department to which the research-worker can turn not only for guidance in the assessment of results already obtained but also for the design of experiment to ensure that the maximum of information is obtained with the minimum of effort. I believe that much of the aversion to the use of quantitative methods in clinical research is due not so much to any inherent difficulty in grasping the common-sense principles as to the drudgery of the arithmetic involved. For that reason I encourage all members of my department to make the fullest possible use of the slide-rule, the Otis King Calculator, the electric calculating machine and books of mathematical tables. Emphasis should also be placed on the amount of information that can be got from the simple graph. Graphic records in clinical work tend to be restricted to records of temperature, and pulse and respiration rates, while much valuable information is missed and many suggestive correlations pass unnoticed because nobody has bothered to plot other observations. I heard of a teaching hospital in which the only height yard stick was in the nurses' home, and nobody had even heard of a patient's height being recorded, with the result that it is impossible to relate the wealth of numerical data contained in its case-records to the norms of height, weight, and age.

The habit of quantitative and statistical thought is not only essential to research but also has a profound influence on the quality of observation without which good practice is impossible. A person so trained is continually questioning the accuracy of the data on which he makes his diagnosis or modifies his treatment.

Notes and News

CASE OF OSCAR WILDE

Fifty years ago Oscar Wilde was not mentioned in polite society. The account of his trials, now published in full[1] under the editorship of Mr. Montgomery Hyde, might then have been brought to the notice of a metropolitan police magistrate for possible suppression and punishment as an obscene libel. Times have changed.

In 1885, during the passage of the Criminal Law Amendment Bill which dealt with the protection of women and girls, Labouchere secured the insertion of a clause (afterwards section 11) creating the offence of indecency between male persons in public or private. Under this section Wilde was eventually tried ten years later. Son of the well-known Irish ophthalmic and aural surgeon, Sir William Wilde, he distinguished himself in classics at Trinity College, Dublin, and, going on to Oxford, obtained two first-classes and the Newdigate prize for English poetry. He married the daughter of an English Q.C. and had two children. If the extravagances of his cult of æsthetic philosophy were caricatured in W. S. Gilbert's *Patience*, his poems and fiction were not to be despised, and his plays were brilliant.

At the age of 38 he made the acquaintance of Lord Alfred Douglas, then 22 years old, the third son of the eccentric Marquis of Queensberry. Father and son hated one another. Violent and vindictive as the Marquis was, he had some justification for objecting to Wilde's intimacy with his son. After threats and abuse, he went to Wilde's club and left for him with the hall-porter a card with the curiously mis-spelt inscription: "For Oscar Wilde posing as somdomite." Largely influenced by Lord Alfred, who saw a chance to strike at his father, Wilde prosecuted the Marquis for criminal libel. Sir Edward Clarke, first obtaining from Wilde the most solemn assurance that there was not, and never had been, any foundation for the allegations against him, undertook the prosecution. Carson was briefed for the defence; the Marquis filed particulars in justification and pleaded that publication had been for the public benefit. Wilde in the witness-box held his own for a time against Carson's cross-examination, displaying the sparkling, if flippant, wit which distinguished his two plays (*An Ideal Husband* and *The Importance of Being Earnest*) then drawing big audiences. But a change came when Carson put to him the names of a series of youths of humble station to whom (as Wilde admitted) he had given dinners, money, and valuable presents. If these young men were called for the defence their evidence might be discounted as that of self-confessed accomplices and, in some cases, blackmailers; but Clarke, highly competent and experienced, advised the breaking off of the prosecution. The Marquis, after all, had accused the prosecutor of "posing," not of actual commission of the crime. A verdict of "Not guilty" was entered and the particulars of justification were thus accepted. Carson's clients sent to the director of public prosecutions a copy of their witnesses' statements; a warrant for Wilde's arrest was applied for; he had time to fly the country, but he did not go. Clarke, maintaining at all times the highest standards of the bar, wrote an offer to defend Wilde without fee in the proceedings which followed.

The arrested man needed indeed all the help he could muster. The press was hostile; his books were struck out of publishers' lists; one of his plays was taken off forthwith, the other a few weeks later; money was short. Charles Gill prosecuted him at the Old Bailey, Carson refusing to have anything more to do with the case. The jury disagreed after five days and a re-trial was ordered. This time the solicitor-general, Sir Frank Lockwood, was for the prosecution; no stone was left unturned. Wilde was convicted and Mr. Justice Wills imposed the maximum sentence of two years' hard labour.

The *Ballad of Reading Gaol* and the biographical memoirs of Lord Alfred Douglas and others kept alive, not without recrimination, various personal questions which matter little now. Had the trials taken place today, the court might have been invited to consider Wilde's mental state. Mr. Montgomery Hyde, in his careful editing of the proceedings, adds one appendix on "The Problem of Wilde's Inversion" and another on "The Prevalence of Male Homosexuality in England." He recalls that, during a debate in the House of Lords in July, 1937, Lord Dawson of Penn homosexuality was now regarded as a pathological might even some day be deemed an "insufficienc or at any rate as much disease as crime. It may take another fifty years to convince the judges and public that these cases are other than—to quote Lo opinion delivered in the same debate—"the result impulses which, like other wicked impulses, are being controlled and can be checked by advic resolution."

OPTION UNDER SUPERANNUATION RE

In a circular letter (E.C.L.80) the Ministry of H out that those practitioners who wish to contract National Health Service superannuation scheme notice by Oct. 4. This option, as was explained in July 3 (p. 30), is open only to those who are insurance policies.

OUTPATIENT FACILITIES FOR PSYCHIATR

The National Association for Mental Health published a 43-page directory of child-guidance outpatient clinics for adult patients. Addresses a *all counties in England and Wales and Norther* Scottish inquirers are referred to the Scottish Ass Mental Hygiene. General practitioners, almoners, workers will find this list useful. Copies may be (1*s*. each or 11*s*. per doz.) from the N.A.M.H., 39, Street, London, W.1.

Edinburgh Post-Graduate Board For Medic

On Thursday, Sept. 16, at 4.30 P.M., in the anato theatre of the university, Prof. J. C. Brash will Modern Trends in Anatomy.

Institute of Laryngology and Otology

On Tuesday, Sept. 14 at 5.15 P.M., at the Gray's Inn Road, London, W.C.1, Dr. A. C. R speak on Dermatology as it concerns the Ear, Throat.

Institute of Psychiatry

Lecture and demonstration courses for students in psychiatry will be held at the institute coming session. Further particulars may be had secretary of the institute, Maudsley Hospital, London, S.E.5.

Royal Free Hospital

On Friday, Oct. 1, at 3 P.M., Mr. L. E. C. N deliver the inaugural address of the school of the Beveridge Hall, Senate House, University of Malet Street, W.C.1. He is to speak on the Imp Team Work with special reference to Hospital Li

British Tuberculosis Association

At a meeting of the association to be held at 26, Place, London, W.1, on Friday, Sept. 17, at 3.15 R. D. Lawrence and Dr. I. M. Hall will speak on losis and Diabetes, and Dr. L. E. Houghton on Therapy and the Bronchus.

International Congress on Industrial Medic

Members of this congress, which will open at th Hall, Westminster, on Monday, Sept. 13, at 11 may register on Sunday, Sept. 12, from 10 A.M. t at Church House, Great Smith Street, S.W.1, and on 14, and 15, at Caxton Hall, Westminster, from 9 to and from 12.15 to 2.30 P.M. During the con secretary, Dr. H. J. Davies, may be addressed at at Caxton Hall.

Air Ambulances.—Morton Air Services Ltd., who a world-wide service of air ambulances from Croydon inform us that their additional address at Liverpool, their advertisement of Sept. 4, has been cancelled.

Corrigenda.—The opening address at the *Congress on Population and World Resources* was g Lord Horder. Sir John Boyd Orr opened the disc the first session.

In the directions for the use of '*Clinitest*' p. 309) five drops of urine plus *ten* drops of water be placed in a test-tube.

---

[1] *The Trials of Oscar Wilde.* Edited by H. Montgomery Hyde, with a foreword by Sir Travers Humphreys: Notable British Trials Series. London: Wm. Hodge. Pp. 384. 15*s*.

ved of one or more of his customary guides. Such lity of mind is compatible with an extensive stock eoretical knowledge and even with the capacity to with clarity and persuasiveness. In my opinion, ver, such men are entirely unsuitable for research or senior medical educational responsibility, because y important function of university education is to what is known in the light of what is not known to foster the attitude which regards the knowledge day as a base from which to evolve the knowledge morrow.

elegant type of research is that which begins an assembly of the available knowledge of some icular phenomenon and the erection on this basis hypothesis which seems to fit the data. This thesis is then used to predict the results of one or series of experiments. These experiments having performed, the degree of correlation between the icted and observed is a measure of the validity of hypothesis. More often than not in clinical science technique gives a somewhat imperfect correlation cating that some substantial variable has not been reciated, or, as one statistical technique expresses it, "residual variance" is of considerable magnitude. illustrations will illuminate this approach:

ldblatt, from a wide range of unconnected clinical, ological, and experimental data, formed the hypothesis permanent reduction of renal blood-flow in mammals nced systemic hypertension. He tested this concept by ated reduction of the lumen of the renal artery in dogs, a relatively complete vindication of the validity of the thesis.

me months ago in our own laboratory a research reached nt at which it became necessary to know with as high gree of certainty as possible whether the air inspired a deep breath was accommodated by an increased nsion of the alveoli in use during quiet breathing, or her additional "reserve" alveoli became ventilated. a knowledge of the volumes of the residual air, alveolar omposition, &c., and by the use of known degrees of xture with an inert gas it was possible to predict the titative changes in alveolar air which could be expected he basis of each of the conflicting hypotheses. Experital observation furnished a very close correlation with the lt predicted on the basis of the large breath being mmodated by distension of the same alveoli used in t breathing.

TRAINING OF RESEARCH-WORKERS

he beginner in research should not be allowed to ark on a project without preparing an outline of hypothesis to be tested and of the possible answers ch the experimental approach may yield. Often ugh this preliminary theoretical approach will reveal t the design of experiment is fundamentally incapable ielding the desired information, a discovery which is ter made before time and effort are wasted. Though nay be clear from the outset that a certain minimum xperiments will be necessary to establish a significant wer, that should not deter the worker from the analysis the results at short intervals. There is no more llectually satisfying experience than to watch the ree of significance steadily increase with replication, on the other hand there is no more mortifying trial to discover after weeks or months of labour that effort expended is largely in vain because some redicted factor or frank error has marred the results. novice should be taught that it is when the results s experiments seem most mysterious and inexplicable he is most likely to make a new and exciting overy. In research as in other spheres of endeavour when things go wrong, and doubt and difficulty t, that ingenuity, morale, and stamina can best be ssed.

ften enough the beginner essays a research project too broad and general in scope to allow of any real progress within a reasonable time; or necessitating such a range of technical processes as to imply an attack by a carefully selected team of experimental investigators. Without experienced direction the result is inevitable disillusionment and frustration, with the acquisition of a sadder and not necessarily wiser frame of mind, all too often tinged with cynicism and revulsion to investigative activity. The approach to a specific research project is along exactly the same lines as the conduct of a military operation—i.e., by the exercise of the scientific method. The problem to be solved is equivalent to the objective whose capture is desired. A critical study must be made of the available information—i.e., in the words of a famous manual of military tactics, "Time spent on reconnaissance is rarely wasted." A careful assessment must be made of the available resources in terms of apparatus, clinical material, and, above all, of the time required to acquire the necessary skills and to perform the experiments. Finally, a very generous time margin must be allowed for unforeseen delays due to technical difficulties, lack of suitable cases, and, to continue the military analogy, for unexpected resistance and difficulty in the reduction and consolidation of intermediate objectives. A full appreciation of the problem both in its abstract and concrete details will often reveal to the beginner the impracticable nature of his scheme; he will realise that he was proposing to engage on a corps front with battalion strength.

It is true that the measurement of cardiac output by the application of Fick's principle and the obtaining of samples of mixed venous blood from the right heart constitutes a valuable procedure, but the actual insertion of the cardiac catheter, in itself not very difficult, is only a dramatic incident in a broad background of skilled collection and gas analysis of samples of blood and respired air. The beginner will probably take much longer to acquire the necessary skill in handling the Van Slyke manometric apparatus than in learning to insert the catheter. If one adds to that the simultaneous recording of right auricular pressure by a Hamilton or Warburg manometer, the whole process becomes a matter for a highly trained team at least one member of which must be exclusively engaged in this work.

The use of radioactive isotopes in clinical research opens up glittering vistas of conquest of knowledge, but while deceptively simple in theory these techniques are complex and costly in application and are beyond the scope of any but the specially trained and experienced investigator.

It is sometimes necessary to disabuse the beginner of the notion that for him clinical research can be done by merely arranging for a series of tests to be performed by the biochemist, the clinical pathologist, or any or all of the various special departments found in the large modern hospital. Though the experienced clinician trained in research method, working in partnership with the biochemist, clinical pathologist, radiologist, &c., can achieve results of the highest order, "request reform research" methods in the hands of the inexperienced can become rich mines of misinformation and often prove an intolerable imposition on the various special departments.

In brief, it is one of the most important duties of the research director to guide his charges to a limited problem which is well within their scope and to make it perfectly clear to them that they must be prepared to carry out the technical details themselves at least as well as any technician. Only thus can they appreciate the variability of the measurements, and in actually doing the work themselves they are much more likely to see new and fruitful avenues of approach.

I know of a famous American laboratory where the research-workers have the minimum of technical assistance but adequate accommodation and excellent workshop facilities. This compulsion to find out and "do" for themselves provides ideal training. I look back with appreciation to the time when for months on end my colleague and I had to measure

He knows that the emphasis he can place on, say, his clinical location of the apex-beat as an index of heart size is strictly related to the accuracy of this method as checked by radiological or pathological examination; that the significance of pain in the right shoulder as evidence of gall-bladder disease depends on how often it is present in proven cases of disease of that organ and how often without such disease; and that the accuracy of the diagnosis of tuberculosis is much impaired if the tubercle bacillus is not isolated.

Quantitative and critical thought confers some immunity to the cardinal sin of certitude, the commission of which betrays a flaw as fatal in the daily practice of the physician as in that of the laboratory worker. Respect for authority in science is based not on the ex-cathedra pronouncement but on the production of sound evidence which stands the test of significant correlation with observation. Clinical practice divorced from scientific discipline undoubtedly leads, or rather has led, to an atmosphere of authoritarianism in which the neophyte does not appreciate the difference between dogma and deduction, comes to have an undue veneration for the logos, and is apt to be blinded to the existence of gaping cracks in the structure of knowledge. Such a dangerous and prematurely senile attitude of mind will not develop in an organisation dominated by a spirit of inquiry in which patients are diagnosed in the light of the most accurate observations, both historical and physical, that human ingenuity can devise and are treated by the method which seems most rational, all with the keenest appreciation of the fallibility and imperfections of these procedures and with the dominant ambition to acquire new knowledge which will lead to better methods.

USE OF LITERATURE

An important part of training in scientific method consists of the proper use of literature. It is fatally easy for the medical specialist to fall into the habit of reading only the journals dealing with his particular branch. Not only must the trainee learn the use of the *Cumulative Index Medicus* and the pitfalls of being content with second-hand cited references, but also he must have ready access to those journals which report applications of the scientific method to clinical problems. Among this group, mention must be made of *Clinical Science* and the *Journal of Clinical Investigation*. The *Journal of Physiology*, though only in minor degree clinical, provides particularly good examples of the proper conduct of biological investigation. Ready access to complete sets of these journals is essential. *Nature* and *Science* provide breadth of outlook and are a fruitful source of new methods. From time to time discovery and technical advance in one department of science may provide the clue which will overcome an impasse in an investigation in a totally different field. Study of good scientific literature develops an appreciation of the importance of the proper reporting of observations and of the relatively ephemeral value of hypothesis and speculation. A large proportion of the interpretation and conjecture in scientific reports is, of necessity, incomplete or even erroneous, but data, especially quantitative data, adequately detailed with sufficient account of the methods to enable reproduction by others, is of enduring value and may provide an indispensable link in a chain of evidence which leads subsequent investigators to some important advance. Though it is given to few to make major forward steps, it should be within the power of many to contribute an accurately fashioned piece to the mosaic of knowledge.

DISCUSSIONS

The colloquium or seminar is a valuable feature of the clinical unit. It provides an opportunity for the trainee specialist to give an account of the progress of his research and to have his particular discussed. It should be the accepted thing that, research comes to an apparent impasse—and that, in limited experience, is frequent—because of either tec difficulties or incomprehensible results, it should be on the agenda for the next seminar. This not provides an opportunity for others to share the exercise of the problem but also is surprisingly of solution. Such meetings are all the more valua as in the case of my own department, they are reg attended not only by clinical colleagues but also physiologists, pathologists, pharmacologists, and ticians. Such meetings should be quite distinct staff clinical meetings, in which the emphasis is on the study of the diagnosis and management individual cases. In addition, directors of should make a point of introducing, as often as their junior associates to the scientific proceedings such societies as the Medical Research Society, Physiological Society, and the Pathological Those whose investigative efforts meet with success become eligible for membership of these societies.

TYPES OF RESEARCH

One comes now to an important aspect of the tion of research and specialist training—i.e., a of the types of investigation. Such is necessary to be in a position to give counsel to the novice. times, of course, little advice is needed, in that beginner comes with a clearly defined and problem which is well within the capabilities of individual, the technical resources of the d the supply of suitable cases, and the time a Such a happy project is, however, extremely rare. it presents, the originator should be the object of ticularly close supervision, because, if to his pr be added diligence and adaptability, he is likely worthy of rapid advancement in investigative m

Apart from obligatory elementary training in methods which may become an essential part of training, the reasons which impel young men to time to investigation are often obscure. Some merely want to produce a thesis acceptable for a degree; others may be profoundly dissatisfied the glaring imperfections, obvious inconsisten scarcely warrantable assumptions which ch the established body of knowledge of some phy phenomenon or disease process; others may constituted as to derive substantial mental and satisfaction from the systematic approach to a A few obviously have uppermost in their minds desire to find out whether they are capable of research, and if so whether a career devoted to research work or the combination of routine practice with a research problem will provide the outlet for their ambitions and abilities. It is impo for those charged with the heavy responsibility selecting candidates for the range of activities lie between, on the one hand, a short training in principles and methods as a part of specialist and, on the other hand, a career devoted to wh research to realise that "job selection" is as yet at best approximate, and that the acid test is observation during a trial period. Some types almost from the outset, clearly unsuited for more than elementary instruction in scientific m as applied to clinical problems. Such persons unusually dependent on guidance, both in their clinical work and in the laboratory; they attach emphasis to the opinions of seniors and have an un regard for accepted hypotheses and dogma and aversion to resolving problems to first principles. T may be likened to the navigator who is seized panic when he finds himself in an unusual situ e, he might soon cease to be a useful practitioner irector of research.

this connexion it is well to meditate on the hapgs in the Museum of Alexandria some 2200 years luring the reigns of the first two Ptolemys. At ime, in that place, there occurred one of the greatest s of scientific discovery in the history of mankind. d and Apollonius placed geometry on a secure ıg, Eratosthenes calculated the size of the earth ame within fifty miles of its true diameter, Hero the first steam engine, Archimedes made several physical demonstrations, and Herophilus contril extensively to anatomy. Few of these great veries made any contribution to the welfare of for over 1500 years, because at the time there ed a complete social gulf between the scientist and artisan. This is in sharp contrast with another escence of genius which occurred in Birmingham ıe latter half of the eighteenth century. At that there existed the Lunar Society, whose members ded such masters of pure science and applied ıology as James Watt, Matthew Boulton, Joseph stley, Josiah Wedgwood, Erasmus Darwin, and iam Withering, under whose influence there was ırkably little delay in the application of inventive ıs to practical problems.

FUTURE OF RESEARCH

is very clear that it will be many years before there be adequate facilities for including research experiof the type outlined in the training of all specialists. act the position will become satisfactory only when of the senior practising specialists have themselves ived such training and are actively educating their rentices in scientific methods along with instruction e purely vocational detail of their specialty. Develop-t depends not so much on material resources in ks, mortar, and costly apparatus—though these a part—as on the multiplication of people whose practice and teaching are consciously, indeed ressively, governed by the rigorous standards of ntific thought. This is not in any way antagonistic he so-called "art of medicine"; indeed the needs humanity are best served by the methods of ight and practice, in particular the habit of rigorous criticism, which are inherent in science.

n the first instance this type of training will of essity be confined largely to teaching hospitals, e such habits of thought and practice require the nulus of preclinical departments and of broad contacts h university faculties of science. One detects a idency in certain circles to suppose in the New Order t the teaching hospitals will be exclusively engaged the instruction of undergraduates, while postgraduate ecialist training will be relegated to non-teaching regional hospitals. Though much practical clinical perience will necessitate work in these hospitals, al isolation from the universities and their hospitals uld be utterly disastrous. I suggest that the aim uld be to group regional specialist centres in the sest possible geographical, organisational, and inteltual relationship to the university. Only thus will re flourish a tradition which is so aptly expressed in quotation from Wordsworth which is the motto of journal *Nature*: "To the solid ground of nature sts the mind that builds for aye."

. . . The ordinary citizen sees little connexion between advance of science and the fact that he is healthy; it is, feels, a quality that other people may lack, but is his right of a superior heredity or habit. Ill health, on the ıer hand, while a fault in other people, is a misfortune himself and a serious reflexion on the state of medical ence."—Sir Henry Tizard. *Nature*, Sept. 11, 1948, p. 396.

STREPTOMYCIN IN NON-TUBERCULOUS INFECTIONS

SUMMARY OF A REPORT TO THE MEDICAL RESEARCH COUNCIL

Clifford Wilson
M.A., D.M. Oxfd, M.R.C.P.
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON; DIRECTOR OF THE MEDICAL UNIT, LONDON HOSPITAL

In December, 1946, the Medical Research Council appointed a committee[*] to arrange clinical trials of streptomycin in non-tuberculous infections, in parallel with the trials in certain forms of tuberculosis which have been organised by another committee of the council. The trials in non-tuberculous infections began at five centres in London and later were extended to eleven centres throughout the country. This report summarises the pooled results of the investigation; more detailed results will be published by individual observers.

Because of the small amounts of streptomycin available, the relative rarity of suitable cases, and the wide diversity of conditions treated, experience of most infections in which streptomycin therapy may be effective is still limited. Even when, as in *Hæmophilus influenzæ* meningitis, a reasonably large series has been studied, the distribution of cases over a large number of centres has led to unavoidable variations in case selection, therapeutic procedure, and bacteriological control. For these reasons present claims must be guarded. Nevertheless, some clear-cut results have been obtained and profitable lines for further inquiry have been indicated.

These trials have been restricted to infections resistant to other forms of therapy, in which bacteriological control of treatment has been possible. With few exceptions the infecting organism has been proved streptomycin-sensitive before treatment has been begun; occasionally—e.g., in infective endocarditis—when penicillin treatment has failed, subsequent attempts to isolate the organisms have been unsuccessful.

The chief value of streptomycin (apart from tuberculosis) lies in the treatment of penicillin-resistant infections due to the gram-negative bacilli, particularly *H. influenzæ*, *Proteus*, *Ps. pyocyanea*, and *Bacterium coli*. The clinical disorders in which treatment has been most effective are septicæmias, meningitis, urinary-tract infections, and local (superficial) infections.

H. INFLUENZÆ MENINGITIS

The results of preliminary trials in the United States suggested that streptomycin might be particularly valuable in this condition; a standard scheme of treatment was therefore recommended in the present investigation.

Dosage.—The intramuscular dosage was 20 mg. per lb. of body-weight daily in divided (four-hourly) doses; and the intrathecal dosage (in saline) was 50–100 mg. as the initial dose, according to age, and 25–50 mg. on subsequent days. Treatment was continued for at least seven days after the cerebrospinal fluid (C.S.F.) became sterile.

Results.—Streptomycin was given in 43 cases, of which 4 received in addition sulphonamides, penicillin, or serum; in 5 others the C.S.F. was reported sterile before streptomycin injections were started. Of the remaining 34 cases, the infection was controlled in 25 (74%) and treatment failed in 9. There was no significant difference in age, duration, or C.S.F. changes between the two groups, but clinically the unsuccessful cases appeared to be more the food and drink, and collect, measure, and analyse the urine, of our group of rabbits. It could be only by practical experience of this sort that one could solve satisfactorily the problem of total recovery of urine from the male rabbit, an animal endowed with a "stream" like a fire hose.

---

[*] Sir Alexander Fleming (chairman), Prof. Ronald V. Christie, Prof. L. P. Garrod, Mr. R. Vaughan Hudson, Prof. H. Raistrick, Dr. Robert Cruickshank, Dr. F. C. O. Valentine, Dr. F. R. Selbie, and Prof. Clifford Wilson (secretary).

In advocating the educative value of a practical training in the intimate details of research I must not be taken as minimising the value, indeed the absolute necessity, of an adequate number of research technicians in the elaborate research projects which the solution of many problems demands. It is, however, essential that members of such research teams have a background of practical experience without which supervision of the work of the technicians is impossible.

For many trainee specialists a suitable investigative exercise will consist of an analysis of some grouping of case-records with a view to evaluating some suspected ætiological factor, the significance of a symptom or sign, the result of a certain therapeutic measure, or the illumination of the natural history of a disease process. Such an essay can be particularly valuable, since the discipline acquired is such as can be applied in later life, such research being specially suitable for the busy clinician who can only snatch an hour here and there. To be of value, though, it has to be well done, for a great deal of harm has resulted from the uncritical assembly of information selected by biased methods from fundamentally inaccurate records. It is particularly in this type of investigation that testing statistically and thinking quantitatively is so essential.

A clinical department proposing to provide research of this type requires a considerable accumulation of full and accurate case-records supported by relevant radiographs, histological preparations, and tissue blocks. At present there are relatively few units, even among the teaching hospitals, in which the case-records are of any value for this purpose. It needs careful planning and constant supervision by senior members of staff to ensure an adequate standard of records. In addition a hospital or group of hospitals requires a statistical department which will, in collaboration with the clinicians, ensure uniformity of practice and the codifying of information by modern methods which will ensure speedy and semi-automatic access to any desired group of cases. At the same time such statistical departments can never compensate for faulty original observation; the quality of the records is utterly dependent on conscientious and careful work in the consulting-room, ward, and laboratory. If I had to name the aspect of clinical work which should come first in a programme of reform, I would unhesitatingly select the preparation and preservation of case-records. Whatever be the merits and demerits of the National Health Service, the prospect it holds of nation-wide individual health-records meets with universal approval.

REPORTS ON RESEARCH

Whether the trainee be destined for a career in academic medicine or in the practice of a clinical specialty, the preparation of a report on his research problem is an important item in his education. In a small minority of instances this will be of sufficiently high standard to merit submission for publication. It is futile to expect that many will reach this standard; it must be evident from a perusal of current medical literature that a considerable proportion of the material that appears in print shows little evidence of scientific method and contributes little if anything to the sum total of knowledge. It is certain that the development of systematic training in investigative methods will greatly raise the standard of medical literature and will lighten the labours of editorial boards. A substantial proportion of these reports will be suitable for submission for the higher degrees of M.D. and M.S. Universities are showing an increasing tendency to award these degrees on the of evidence of having done original research or applied the scientific method to a problem in or surgery, using these terms to embrace virtually whole field of human biology. Interpreted in this these qualifications cease to be repetitions of the bership and fellowship and become tests of different attributes.

Most people have much to learn in the of such reports. It is extraordinary how the tendency to confuse quantity with quality think that any paper or thesis must be lengthy good. Economy of words, both spoken and just as important as the economy of material the slogan "Time is money" is as true in the and the laboratory as in the factory and I urge students to write papers as if they were cabling a story at a shilling a word. The report begin with a concise enunciation of the problem, should then give the design of experiment in detail to make it possible for others to repeat the An account of the results should be followed by cussion of the conclusions in the light of relevant work. Illustrations must be clear and to the Quantitative data require tabulation, and correlation should be used whenever possible. of data, though often better relegated to an must be sufficiently full to enable others to fully or refute the deductions made by the author. must be accurately listed, and abbreviations follow those of the *World List of Scientific* Some years ago the *Journal of Physiology* issued useful pamphlet entitled "*Suggestions to* which is still in print and can be obtained editor, at the Physiology Laboratory, consulted in the journal.

An essential attribute of those charged encouragement and direction of research is enthusiasm; *a cold hypercritical destructive* with the immature efforts of students inevitably the work of any educational organisation. criticism there must be, but the student who difficulties—and good students and promising gators are always in difficulties—needs and must be made to feel that his failures are and indeed desirable steps to success. Emerson right when he said that "Nothing great was ever without enthusiasm."

FUNDAMENTAL RESEARCH

It is hard to discuss the subject of research touching on the question of fundamental as applied investigation. Some use these terms as if had a precise meaning and were a basis for classification. In so far as all good science interpret phenomena in terms of first follows that all good research is fundamental of the problem; *the question of* whether the is immediately applicable to some circumstance environment becomes a secondary consideration. I *that a common basis for the use of these terms,* mutually exclusive sense, *implies* "*fundamental*" such as to have no practical use. This is an and artificial differentiation and can be avoided closest possible coöperation between clinicians laboratory workers; such a collaboration maximum when these activities are combined in and the same person. There must be *moments* in life of all clinical investigators when the desire to with single-minded devotion a particular research ders some intolerance of the *responsibilities* of care of patients and teaching, but a brief pause reflection brings a realisation that, without the of close contact with *individual* problems of health preliminary report in 1946 from this department on use of intrathecal streptomycin in meningitis was)pointing (Cairns et al. 1946); severe toxic reactions observed, and in only 1 of the 5 cases due to gram-tive organisms did the patient recover. It was ficant, however, that the solitary survivor was the patient to receive treatment early in the infection to achromobacter). All of the 3 patients infected Ps. pyocyanea died: in 2 treatment was begun when spinal block was already established and pus present in the cerebrospinal fluid (C.S.F.); the third ent died of respiratory failure shortly after the first tion of streptomycin.

nce that date we have treated 5 further patients, the results with purer supplies of streptomycin and ier treatment are more encouraging: 3 recovered infected with *Ps. pyocyanea* and 1 with *Bact. coli*); nfected with achromobacter) died; and 1 (infected 1 *Proteus*) did not respond to streptomycin but wered spontaneously.

f these 5 patients 4 received full doses of sulphondes during the streptomycin treatment. Though e cases of meningitis due to gram-negative organisms ond to sulphonamides, the rapidity of response to ptomycin treatment in the 3 successful cases leaves doubt about the effective agent, but a synergistic on is not excluded. The possibilities of successtreatment of a meningitis due to gram-positive gram-negative organisms with penicillin and ptomycin combined is illustrated by case 4.

DOSAGE

he accompanying table gives the details of the ses treated. In 3 the infection followed the surgical oval of a cerebral tumour or abscess, and in 2 a onic ear infection. Since supplies of streptomycin e short, treatment had to be confined to the intraeal or ventricular route; but undoubtedly this should combined with systemic streptomycin, particularly en there is an extracranial primary focus. A strength 10,000 units* per ml. in normal saline was used, 1 the usual dose was 50,000 units intrathecally daily 1 continued, when supplies were adequate, until the F. had been sterile for four or five days. In 2 cases intraventricular route was used as well, and in ase, which followed excision of a cerebellar abscess 1 developed a spinal block, streptomycin was injected ough the cerebellar decompression into a C.S.F. ulus. With this dosage the concentration of the drug naining in the C.S.F. twenty-four hours after the ection, though very variable, was usually well above e bacteriostatic level required for the particular ganism and often five times or more higher.

RESULTS

In 3 cases (2 of *Ps. pyocyanea* and 1 of *Bact. coli* eningitis) the results were very satisfactory, the ganisms disappearing from the C.S.F. after the first jection; this even obtained in 1 case of *Ps. pyocyanea* eningitis, where the patient had two relapses in three d a half months, the organisms disappearing each me after the injection of streptomycin. In 2 cases ere was no improvement: 1 (*Proteus*) due to lative insensitivity to streptomycin (25 units per l.) and probably insufficient treatment; and 1 chromobacter) which proved fatal owing to rapidly veloping resistance to streptomycin while receiving parently adequate dosage.

TOXICITY

With the doses used no toxic effects of any kind were served; nor was there any increase in the cell or protein content of the C.S.F. attributable to the streptomycin. The largest single dose injected into the lumbar theca and into the ventricle was 100,000 units.

BACTERIAL RESISTANCE

In the 2 cases which did not respond to treatment organisms were finally grown from the C.S.F. which were very resistant to high concentrations of streptomycin.

Case 1 (see table).—A man of 33 had a very chronic *Proteus* meningitis secondary to an ear infection which did not respond to large doses of sulphonamides, and on two occasions a short course of intrathecal streptomycin was given (100,000 units intrathecally daily for four days) without effect on the C.S.F. or on the clinical condition. It is unfortunate that the sensitivity of the organism to streptomycin was not tested before treatment. Two months after the second course the organism was sensitive only to streptomycin 50 units per ml. At this stage the patient began to improve slowly, and now, eight months after the onset, he is doing full work and is well, apart from mild daily headache; the C.S.F. contains only 4 cells (3 lymphocytes) per c.mm. and 40 mg. of protein per 100 ml., culture being sterile.

In this case it should be noted that neither of the two courses of streptomycin lasted longer than four days. The case illustrates that, unless treatment is effective and adequate at the beginning, the infecting organism may become resistant to all chemotherapy.

In the second case resistance to the drug rapidly developed under apparently adequate treatment.

Case 2 (see table).—A boy, aged 9 years, developed a postoperative achromobacter meningitis three days after removal of a medulloblastoma of the vermis. The organism was shown to be insensitive to penicillin but sensitive to streptomycin 10 units per ml. Treatment was begun with 50,000 units into the ventricle and 50,000 units intrathecally. Twenty-four hours later a concentration of 63 units per ml. remained in the C.S.F., and a further 75,000 units was injected. Despite this large dosage the organism was again grown from the C.S.F. next day and was now insensitive to 64 units per ml. Streptomycin 50,000 units was given daily for five days, and the drug was then stopped. During these days the C.S.F. was sterile, and the cell-count, previously 1700 per c.mm., fell to below 100 per c.mm., though the amount of protein remained high and the clinical condition was unchanged. Subsequently the organism was recovered repeatedly from the C.S.F., and the child died thirty-five days after onset of the infection. Eleven days after the beginning of streptomycin treatment the organism was insensitive to streptomycin 100 units per ml.

Whether resistance to streptomycin is acquired as a result of treatment or is a natural resistance of some of the organisms, the more sensitive ones being killed early, is not yet known, but the very rapid appearance of resistance, together with the favourable cell response in the C.S.F., with sterile cultures for several days in cases such as the one described above, suggests the latter explanation, the resistant organisms later multiplying and producing a fatal result.

RELAPSES

In this series the only case to relapse after apparently successful treatment was case 4. Here the reason was obvious and one which should be borne in mind when dealing with these infections—the presence of an inadequately treated primary focus.

Case 4 (see table).—A man, aged 51, had had a discharging left ear for twenty years. In March, 1946, he became acutely ill with symptoms suggesting a cerebellar infection. A radical mastoidectomy was performed, and later a cerebellar abscess was tapped through the mastoid wound. He slowly improved despite the formation of a cerebral fungus through the wound and two attacks of meningitis. In July he relapsed suddenly, and in August was transferred to the Radcliffe Infirmary.

On admission he had a large fungus presenting through the mastoid wound which was discharging pus from which *Staph. aureus* and *Ps. pyocyanea* were cultured. He was treated with intramuscular penicillin and daily dressings to the fungus, and this finally healed.

---

* 1 unit = 1 μg. of streptomycin base.

severe. Where typing was carried out the organism was found to be Pittman type b. When treatment was successful the C.S.F. usually became sterile within twenty-four hours of the first intrathecal injection. Streptomycin was effective in 13 cases which had relapsed on other treatment, and in 9 cases in which the infection had been present for two weeks or longer; 4 patients relapsed after an initial response to streptomycin, but the organism remained sensitive and further treatment with streptomycin alone was successful. The principal cause of failure was the development of resistance by the organism; this occurred in 7 of the 9 failures, sensitivity changing from 0·5 to as high as 5000 units in 1–4 days.

From this series it appears that in *H. influenzæ* meningitis streptomycin alone is probably as effective as any other form of treatment at present available. The development of resistance is, however, a serious drawback, and it has been decided to use in future trials a combination of streptomycin, penicillin, and sulphonamides from the start.

OTHER FORMS OF MENINGITIS

Streptomycin was given in 14 cases of meningitis due to penicillin-resistant bacteria. The causal organisms included *Bact. coli*, *Ps. pyocyanea*, *Staphylococcus pyogenes*, *Proteus*, and *Streptococcus fæcalis*. In the majority of cases the meningitis developed after operation for cerebral abscess or cerebral tumour. The infection was controlled in 11 instances. Streptomycin is therefore a valuable new therapeutic agent in pyogenic meningitis due to penicillin-resistant organisms.

SEPTICÆMIAS

Streptomycin was given in 5 cases of subacute bacterial endocarditis due to *Strep. viridans* or to *H. influenzæ*, and in 1 case of uncertain nature. Except in the last-named case, the response to streptomycin has been only temporary; 2 cases of septicæmia without endocarditis, due to *Ps. pyocyanea* or to *Bact. coli*, have responded satisfactorily.

URINARY-TRACT INFECTIONS

A series of 61 patients with urinary-tract infection due to *Bact. coli*, *Ps. pyocyanea*, *Proteus*, *Staph. pyogenes*, or *Strep. fæcalis* was investigated in ten centres. In roughly half the cases the infection has been controlled by intramuscular administration of 3 g. streptomycin daily for 1–3 days. Failure was almost always due to the development of resistance. Like other antibacterial agents, streptomycin has a limited value where there is some underlying condition which is liable to lead to recrudescence of the infection.

LOCAL SEPSIS

Streptomycin was given to 55 patients with local infections, including a wide variety of lesions such as infected burns, operation wounds, superficial ulcers, sinuses, abscess cavities, and septic skin conditions. The bacterial causes were similar to those detailed in the preceding paragraph. Daily applications of a saline solution of streptomycin (2 mg. per ml.) have been used either alone or combined with intramuscular therapy. The results are favourable, particularly in superficial lesions, provided that all necrotic tissue is removed. A standard technique is essential. Streptomycin has been used effectively as a cover for skin-grafting. In a proportion of cases failure has been attributable to the development of resistance.

RESPIRATORY INFECTIONS

Chronic lung infections due to bronchiectasis and lung abscess (14 cases) have been treated by inhalation and intramuscular injection. Though a temporary reduction in the bacterial content of the sputum has been noted the cases showed little if any clinical improvement. The results of a preliminary trial in cough were inconclusive. More experience is of *acute* lung infections due to penicillin-organisms.

INTESTINAL-TRACT INFECTIONS

Streptomycin 2–4 g. spread over seven days has given by mouth in 42 cases of infantile
Sensitive organisms rapidly disappear from the
As the infecting agent in this condition is not
the same, it was to be expected that the results
in different centres would vary. Some centres
clinical benefit, but so far treatment has not
sufficiently controlled to warrant any definite
Further trials, in which streptomycin will be
alternate cases, are being undertaken. A small n
of cases of ulcerative colitis and of typhoid fever
been treated by oral and intramuscular adm
with negative results.

SUMMARY

In this series of cases streptomycin has often
successful in controlling:

(1) Meningitis: *H. influenzæ*, *Bact. coli*, *Ps.* *Proteus*, and *Staph. pyogenes*.
(2) Septicæmia: *Bact. coli* and *Ps. pyocyanea*.
(3) Urinary infection: *Bact. coli*, *Proteus*, *Ps. pyo* *Strep. fæcalis* and *Staph. pyogenes*.
(4) Local sepsis: *Bact. coli*, *Proteus*, *Ps. pyocyanea*, *pyogenes*, and *Strep. hæmolyticus*.

There have, however, been examples of almost
type of infection in which the micro-organisms
became resistant. Courses of treatment should th
be planned to exert the greatest possible influenc
the beginning. The effect of combining strep
with other agents, such as the sulphonamides, is
investigation.

Owing to the short periods of administration
symptoms have been unusual and of slight imp
Urticarial rashes and skin irritation at the site of
application have occasionally been noted.

STREPTOMYCIN TREATMENT OF MENINGITIS DUE TO GRAM-NEGA SAPROPHYTES

WALPOLE LEWIN
M.S. Lond., F.R.C.S.

R. L. VOLLUM
M.A., D.Phil. Oxfd

From the Department of Surgery, Radcliffe Infirmary,

MENINGITIS due to saprophytic gram-negative
isms such as *Ps. pyocyanea*, *Proteus*, and co
bacteria is uncommon but carries a high mortal
These organisms are relatively or absolutely insensiti
to penicillin; and the response to sulphonamide thera
is often unsatisfactory.

Infection usually arises as a complication of spi
analgesia (Evans 1945, Kremer 1945, Vuylsteke 19
Davidson 1947), neurosurgical operations, or the int
thecal injection of penicillin (Botterell and Magner 194
In wounds of the head and of the spine penicillin h
been so effective in combating infections due to gra
positive organisms that the pathogenicity of th
gram-negative organisms, when introduced into t
subarachnoid space, has become more apparent. The
Lewin (1948) showed that nearly a quarter of the ca
of meningitis following penetrating head wounds in t
latter phases of the late war, when penicillin was fre
available, were due to these organisms. Besides pe
trating wounds of the head and spine and operation
a chronic infection of the ear may cause a meningit
in which these gram-negative organisms are wholly
partly responsible. Coliform meningitis occurs in infant
sometimes with a recognisable focus elsewhere in th
body, but it is very rare in adults.

since collections of purulent exudate and debris
revent free diffusion of antibiotics. These were
bly the main factors in the failure of streptomycin
'e the 2 cases of *Ps. pyocyanea* meningitis reported
usly (Cairns et al. 1946). For these reasons
early treatment before pus forms is a vital factor
cessful treatment.

point was emphasised recently in the treatment of
operative infection beneath the scalp flap of a patient
n old gunshot wound of the head. A small abscess
beneath the scalp contained about 10 ml. of pus,
grew a penicillin-sensitive hæmolytic streptococcus
resistant *Staph. aureus.* The streptococcus quickly
eared with local instillation of penicillin, but the
aureus remained and was resistant to penicillin 65 units
l. but sensitive to streptomycin 1·25 units per ml.
the next five days a total of 260,000 units of strepto-
was injected into the cavity. At the end of this time
uld still be aspirated which was very acid in reaction,
aureus was still present, and the sensitivity to strepto-
was unchanged. The local concentration of strepto-
must have been many times the bacteriostatic level,
here was absolutely no response. The pus was
uently drained with rapid subsidence of the infection.

e appearance of resistant strains of the organism is
er important factor in deciding the success or
e of streptomycin therapy, and it is most important
sure that the initial doses are sufficiently large.
ver, though the doses used here give an adequate
ntration in the C.S.F. over twenty-four hours for
very sensitive organisms, there are often well-
ed differences in streptomycin levels in the C.S.F.
y-four hours after injection in the same patient.
one patient after 100,000 units given intrathecally
ed a concentration of 25 units per ml. remaining
e C.S.F. twenty-four hours later; yet a similar
next day gave only 8 units per ml. after twenty-
hours. It is therefore essential not only to
the sensitivity of the organism before beginning
ment, so as to ensure an adequate initial dosage,
also to check C.S.F.-streptomycin levels during
ment.

tunately these infections, though severe, are usually
lminating, and in the present state of our knowledge
wise, where possible, to begin treatment with
adiazine and defer streptomycin treatment until
ensitivity of the organism has been tested in vitro.
adiazine is effective in some cases. With an
ism sensitive to concentrations up to 10 units
nl., streptomycin should be injected intrathecally
in doses of 50,000–100,000 units and continued
the C.S.F. has been sterile for at least five days.
n the causal organism is relatively insensitive,
er C.S.F.-streptomycin levels can be obtained by
thecal injections twice or thrice daily. When
lies are available, systemic streptomycin should also
iven not only to deal with other foci of infection
also because streptomycin passes the blood-C.S.F.
ier in appreciable quantities, particularly in acute
ngitis.

ck of response to streptomycin treatment in a
ngitis due to a sensitive gram-negative organism
be due to (1) inadequate dosage, (2) developing
tance (or resistant strains) of the organism, (3) an
eated primary focus, or (4) pus formation.

wish to thank Sir Hugh Cairns for his advice in
reparation of this paper.

STREPTOMYCIN IN PULMONARY TUBERCULOSIS

REPORT ON TEN CASES

R. Y. KEERS
M.D. Edin., M.R.C.P.E., F.R.F.P.S.
MEDICAL DIRECTOR, RED CROSS SANATORIA OF SCOTLAND

THE value of streptomycin in the treatment of meningeal and miliary tuberculosis having been established, its properties in other forms of tuberculosis are now being explored. Such reports as have appeared, mainly in America, suggest that streptomycin may have an almost specific effect on tracheobronchial tuberculosis (Brewer and Bogen 1947, Canada 1947, Parnal et al. 1947), and a beneficial effect on laryngeal tuberculosis (Black and Bogen 1947, Shamaskin et al. 1947) and intestinal tuberculosis (Sweany 1947), while Hinshaw et al. (1946) reported encouraging results in the treatment of draining sinuses of tuberculous origin. The results in purely pulmonary lesions are much less definite, but at least temporary improvement has apparently followed its use in some cases of predominantly exudative disease (Shamaskin et al. 1947, Cassidy and Dunner 1947, Allison and Nilsson 1947).

Opportunities for the clinical study of streptomycin in Britain have so far been limited, but as supplies are likely to increase in the near future an account of a very small series of cases treated during the first half of 1948 may be of interest.

Through the generosity of the American Red Cross a consignment of 600 g. of streptomycin was presented to the Scottish Red Cross Sanatorium at Tor-na-Dee early this year. The selection of suitable cases for treatment required much thought, for this generous gift had to be utilised to the greatest advantage. The cases selected were (1) a severe tracheobronchial tuberculosis, (2) a tuberculous chest-wall sinus persisting after a thoracoplasty for tuberculous empyema, (3) two cases of acute exudative pulmonary tuberculosis, and (4) a small contralateral spread of disease following thoracoplasty. The remaining streptomycin was used as a cover during the stages of thoracoplasty operations in cases in which there seemed to be an appreciable risk of extension of the disease.

Dosage.—All cases received 1 g. of streptomycin in the twenty-four hours, given in two doses of 0·5 g. at 8 A.M. and 8 P.M. Administration was by intramuscular injection and no local application of the drug was tried.

CASE-RECORDS

Case 1.—A man, aged 43, was admitted in November, 1946, with a year's history of cough, sputum, and loss of weight. His sputum was T.B.-positive and a radiogram of his chest showed infiltration in the upper and mid zones of the left lung, with tomographic evidence of cavitation. "Roof-tiling" of the ribs over the affected area, with deviation of the trachea to the left, suggested a widely adherent apex and was accepted as a contra-indication to artificial pneumothorax. Left upper thoracoplasty was considered to be the treatment of choice. Four weeks after admission, however, there was radiological evidence of extension of the disease in the left lung, with the formation of a new cavity in the mid zone, this being rapidly followed by a further spread of the disease to the lower zone. This was accompanied by increased cough and sputum and a deterioration in the patient's general condition. Brief febrile bouts occurred, associated with a complete cessation of sputum. Major surgery was contra-indicated meantime, and a left phrenic crush, supplemented by pneumoperitoneum, was carried out. Some benefit ensued and the X-ray appearance improved, with gradual clearing of the fresh infiltration in the lower lung field. This benefit was only temporary; the cough increased in severity, developing a harsh brassy note, febrile episodes with sputum retention

In October the cerebellar abscess was excised. After this excision the patient had a recurrence of the meningitis. *Staph. aureus* and *Ps. pyocyanea* were grown from the C.S.F. He improved on intrathecal and systemic penicillin and, later, sulphadiazine by mouth; but after eleven days he relapsed, both organisms were grown from the C.S.F., and a spinal block developed. Local penicillin was now given into the C.S.F. loculus which had formed beneath the cerebellar decompression, and from this site also both organisms were obtained. With this treatment the *Staph. aureus* disappeared but *Ps. pyocyanea* remained in pure culture. Streptomycin 20,000 units was now injected daily for two days, at the end of which the loculus had completely subsided.

A fortnight later the patient's temperature rose sharply to 102°F, the loculus reappeared, and once more turbid C.S.F. containing both organisms was withdrawn. After two injections of penicillin 10,000 units the *Staph. aureus* disappeared, and at this stage streptomycin 40,000 units was injected as well. All subsequent cultures were sterile, and for the next seven days penicillin 60,000 units and streptomycin 80,000 units were given daily through the loculus, which steadily diminished in size. After four days of this treatment the patient's temperature settled to normal for the first time since his operation, and he began to improve. He made a steady convalescence over the next three months and was finally discharged from hospital afebrile; the cerebellar decompression was soft, but the spinal block was still present.

He relapsed, for the third time after the excision of his abscess, a fortnight after discharge from hospital, and this time *Ps. pyocyanea* and *Strep. viridans* were grown from the loculus, which had reappeared. Once more combined therapy was successful. *Ps. pyocyanea* disappeared after the first injection of streptomycin 50,000 units, and *Strep. viridans* after the fourth instillation of penicillin. Systemic and sulphadiazine were also given. In view of this Mr. G. Livingstone was consulted, who advised ro of the mastoid. This was done while the patient was on combined therapy daily. At operation a petrositis present, and the cochlea was found to be filled with Infection had been reaching the C.S.F. via the This operation did not cause the meningeal infection to up, and the patient made a steady convalescence, streptomycin being continued this time for twenty-one and penicillin for six days. The spinal block

The patient was seen again nine months later, w ear was dry and there had been no recurrence of the

The *Ps. pyocyanea* in this instance remained sensitive to streptomycin despite the use of strep on two previous occasions. This supports the streptomycin resistance is more likely to be than acquired.

COMMENT

The results in these few cases suggest that st will be of value in treating meningitis due to gram-negative organisms. Undoubtedly the dif between these results and those of two years ago is to purer streptomycin and earlier institution of tre before frank pus or spinal block has developed. activity of streptomycin is seriously impaired in presence of pus. As Abraham and Duthie (1946) shown, this is primarily due to the associated of the pH of the medium. In addition, if the has reached the stage of pus formation, it impossible to obtain an adequate concentratio streptomycin throughout the cerebrospinal fluid

DETAILS OF TREATMENT WITH STREPTOMYCIN IN 5 CASES

Case no.	Age (yr.)	Source of infection	Bacteriology	Duration of meningitis before streptomycin treatment (days)	White cells per c.mm. in C.S.F. at height of infection	Streptomycin details: Route	Largest single dose (units)	Total dosage (units)	Sterile C.S.F. obtained	Initial sensitivity of organism (units per ml.) 1 unit = 1 µg. of streptomycin base. L = lumbar theca. V = ventricle.

ais time a total of 66 g of streptomycin had been given. pneumoperitoneum had been maintained gently through-put no attempt had been made to achieve maximum tion, owing to the severity of the patient's illness and ifficulty of fluoroscopic control.

he time of writing his progress has been well maintained; nperature is now normal and it seems possible that he t become a candidate for further collapse therapy, with ospect of securing eventual control over the disease.

e 6.—A man, aged 24, had a left upper thoracoplasty d out in the sanatorium in March, 1948, to deal with a extensive area of infiltration involving the upper third left lung, where there was tomographic evidence of tion. Artificial pneumothorax was not possible because previous left pleural effusion of some severity. After cond stage of the operation a small area of infiltration red in the upper zone of the right lung, which had usly been clear. The appearance of this infiltration ded with a rise in the E.S.R. to 20 mm. in one hour.

ourse of streptomycin was begun immediately, and a later, when a total of 30 g. had been given, the lesion right lung had cleared completely and the E.S R. had ved to 1 mm.

patient has since gone ahead steadily; he is now up bout for several hours daily and should be ready for rge in about 2 months' time.

ses 7, 8, 9, and 10.—The balance of our supply of omycin was used to provide cover during the stages of coplasty in four cases in which there was thought to be usual risk of complications. In two of these there was ge to the lung base as a result of previous pleural effu-while the remaining two had impaired diaphragmatic ion owing to a delayed recovery of movement following ic-crush operations. Streptomycin was given in a e of 1 g. daily for 96 hours before and after each stage e operation. All four cases pursued a smooth and nplicated course throughout.

complications or *side-effects* which could be attri- to the streptomycin were noted in any of the cases.

DISCUSSION

report on a small series of diverse cases such as these be regarded as of interest rather than of value, but ay help in suggesting the type of case which is to derive most benefit from this antibiotic.

e response of the bronchial disease, the chest-wall , and the laryngeal lesion was prompt and unmis-ble, as one would have anticipated from the rican reports already cited, and this suggests that tomycin will find its greatest sphere of usefulness in management of the extrapulmonary sequelæ of rculosis.

se 4, an active pulmonary lesion of exudative type, very disappointing. American experience had sug-ed that some benefit might have been expected in a case, and one had hoped that, by using strepto-cin to control the exudative phase, the patient might e been fit for thoracoplasty fairly soon. As it is, course of the illness has not been shortened in way.

he case of tuberculous pneumonia (case 5), on the r hand, did appear to benefit appreciably and con-ned to the experience of Allison (1947) in that the r and constitutional symptoms subsided early, while ological improvement was delayed for some weeks.

he part played by the streptomycin in case 6 and the four thoracoplasty cases in which it was used phylactically is impossible to assess. The small ralateral lesion in case 6 might well have resolved ntaneously.

CONCLUSIONS

he decision to use streptomycin in any case of monary tuberculosis should be taken only after most eful consideration. The benefit to the patient is by means certain, and this possible benefit must be ghed against the danger of producing a streptomycin-stant strain of bacilli in a particular case and thus creating a future public-health problem. On the available evidence there appear to be very few purely pulmonary cases in which the use of streptomycin could be advised.

This very limited experience with streptomycin suggests that it may have a definite value in the treatment of the extrapulmonary complications of pulmonary tuberculosis.

Its use in tuberculous pneumonia, to prepare the way for effective collapse therapy, is probably justified in view of the high mortality associated with this form of the disease.

My thanks are due to the American Red Cross, whose generous gift of streptomycin made the treatment of these cases possible, and to Mr. F. J. S. Gowar, F.R.C.S., and Mr. E. G. Collins, F.R.C.S., for carrying out the bronchoscopic and laryngeal examinations.

THE EOSINOPHIL CELL

STUDIES IN HORSE AND CAMEL

FREDERIC DURAN-JORDA
M.D. Barcelona
DIRECTOR, PATHOLOGY DEPARTMENT, ANCOATS HOSPITAL, MANCHESTER

WHILE investigating the secretion of red blood-cells by eosinophils I was interested to learn that the eosinophils of the horse contained granules resembling small red blood-cells (Dr. Leandre Cervera, personal communication). Arrangements were therefore made for a thorough study of the blood and other tissues of the horse, and from this it was found that the granules of the eosinophils in the peripheral blood were far larger than those found in various other mammals, including man. The granules varied in size from cell to cell, some of them being as large as a small red blood-cell (fig. 1). On micro-incineration the granules left ashes behind, as happens with the granules in man. A study of the gastric and intestinal mucosa of the horse showed that, as in the other herbivora, the eosinophils arose from those organs where the red blood-cells appeared to be secreted in situ (fig. 2), a phenomenon similar to that described for the abomasum of different hervibora (Duran-Jorda 1945). In the spleen of the horse were very many eosinophils, in some of which the granules were as large as small red blood-cells.

In spite of my being able to show objectively the secretion of the red blood-cells by the eosinophils in

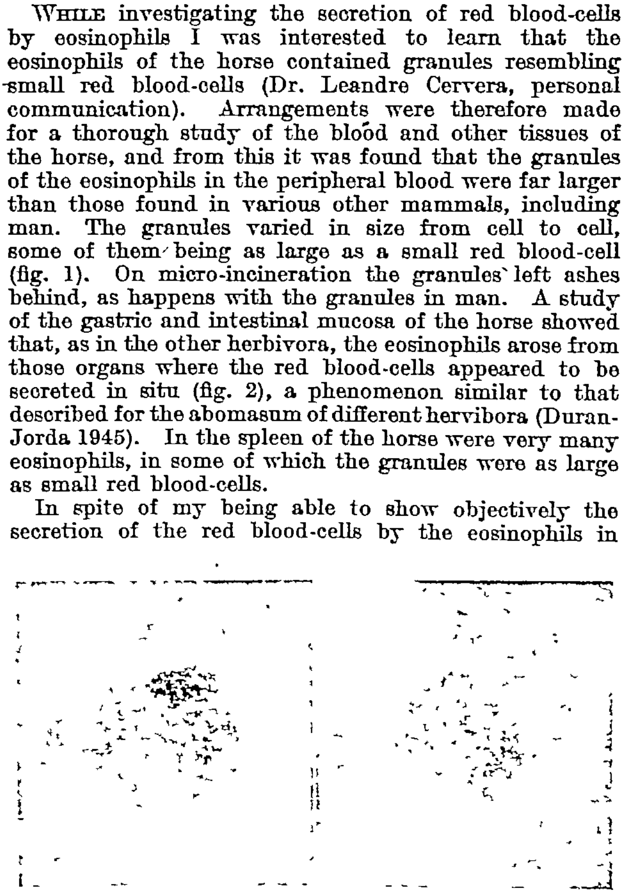

Fig. 1—Horse's blood showing granules of different sizes, some like small red blood-cells, in eosinophils.

recurred, and the cavitation in the left upper and mid zones became increasingly obvious. The whole clinical picture now suggested tracheobronchial tuberculosis, which was confirmed by bronchoscopic examination in June, 1947, when extensive ulceration of the left main bronchus was seen.

It was now a question of marking time until streptomycin became available, and the status quo was maintained with some difficulty until April, 1948, when the American supply was received. On April 13 a further bronchoscopy was carried out, when œdema of the carina was noted, with ulceration on the left side. Granulations were present in the left main bronchus almost to the level of the carina.

A course of streptomycin was begun on April 16. Within a fortnight there was a well-marked improvement in symptoms, the severity of the cough had diminished, sputum was decreasing, and the patient's general condition was improving rapidly. Bronchoscopy on May 14 showed a remarkable clearing of the bronchial lesions, with healing of the ulcerated areas. The improvement was so dramatic that it was decided to proceed with the thoracoplasty operation, and the first stage was carried out on May 25, the second and third following on June 8 and 29. There were no postoperative complications. Bronchoscopy on July 8 showed some hyperæmia of the left main bronchus, with few granulations. Streptomycin was stopped on July 24, when 100 g. had been given.

The patient has continued to improve in all respects; sputum is diminishing steadily in amount and is now T.B.-negative on direct examination, and X-ray examination shows a satisfactory collapse of the left lung following the thoracoplasty.

Case 2.—A man, aged 25, was admitted in February, 1947, with a limited lesion in the right upper zone, where a small cavity was visible behind the clavicle. A right artificial pneumothorax was begun shortly after admission and adhesion section was carried out some 5 weeks later. Immediately after the adhesion section the patient developed a very acute pleural effusion, with high fever and much constitutional disturbance. Attempts to secure pulmonary re-expansion were defeated by very rapid pleural thickening: the fluid became turbid, contained many lymphocytes, and was T.B.-positive on guineapig inoculation. Intensive aspiration was continued until November, 1947, by which time the patient's general condition had sufficiently improved to permit obliteration of the pleural space by thoracoplasty, and the operation was accordingly done in December, 1947. There was a stormy convalescence which caused considerable anxiety and subsequent progress was slow, but X-ray examination indicated that the desired obliteration of the infected pleural cavity had been secured. A sinus, however, formed at the lower end of the operation scar and continued to discharge over a period of weeks. Bacteriological examination of this discharge showed tubercle bacilli, and typical tuberculous tissue was demonstrated in a biopsy specimen from the sinus wall. The sinus itself was about 5 in. long and showed no tendency to heal.

A course of streptomycin was begun on April 20, 1948, and 14 days later a definite improvement was noted in the sinus, which appeared to be closing. This was confirmed by injection of iodised oil. Subsequent progress was steady and uninterrupted, final healing being recorded on June 2. The streptomycin was continued until June 18, when a total of 60 g. had been given.

The patient was discharged from the sanatorium on July 20 in excellent general condition, free from all chest symptoms, and with the tuberculous sinus firmly healed.

Case 3.—A man, aged 27, arrived at the sanatorium in October, 1946. His general condition was extremely poor, he was grossly anæmic, and X-ray examination showed extensive infiltration involving the upper halves of both lungs but without any notable degree of cavitation. The larynx was severely involved, with gross œdema and infiltration of the epiglottis and arytenoids. He complained also of severe diarrhœa, and barium examination showed an advanced colitis which was accepted as tuberculous. The prognosis was regarded as very bad and the patient was kept on strict bed-rest and voice rest for many months. The anæmia proved so intractable as to raise the question of a tuberculous infection of the bone-marrow, but this could not be confirmed by sternal puncture, and eventually a response was obtained to a series of small blood-transfusions. The intestinal lesion responded also to intensive treatment with intravenous calcium gluconate and a high-vitamin diet, and by May, 1947, the alimentary function was completely normal and the patient was gaining weight. Meantime the pulmonary was showing evidence of healing, but the situatio larynx was thoroughly unsatisfactory, there being now tion of the epiglottis with involvement of both vocal A course of calciferol was given, which for a time p some improvement but which had to be terminated ev owing to symptoms of intolerance. The laryngeal then remained static for some months but began to de again in February, 1948. Meantime the pulmonary had steadily improved, the sputum was T.B.-negati the patient's general condition was reasonably good.

The retrogression of the laryngeal condition promp use of streptomycin, which was begun on April 20, From that time onwards there was steady improv Swelling and œdema subsided, the lesions of the vocal cleared rapidly, and by the beginning of July he practically complete, apart from two small ulcerated the epiglottis which were dealt with by the electr By July 23 a total of 90 g. of streptomycin had been and the course was terminated.

The patient was discharged from the sanatorium in final X-ray examination having shown complete hard the infiltration in both lungs, while what little remained was T.B.-negative both on concentration culture.

Case 4.—A man, aged 26, was admitted on Jan. 14 with a history of an acute febrile illness 8 weeks pre An X-ray film of his chest at that time had shown of exudative disease in the right upper and mid zo admission his general condition was rather poor, mildly febrile, and his sputum, although very lim amount, was T.B.-positive. An X-ray film of his suggested that there had been some clearing of the infil on comparison with the film taken at the outset of the i After a month's bed-rest, however, there was evid extension of the disease, accompanied by a sharp rise erythrocyte-sedimentation rate (E.S.R.) from 5 mm. to in one hour. A right phrenic crush and pneumope were carried out, but only a very moderate elevation diaphragm resulted, because of adherence between the diaphragm in the posterior half. Four weeks later t been no improvement, the patient was still febrile tending to lose weight, and the exudative lesion in lung was gradually extending.

A course of streptomycin was begun on April 20 continued until July 28, a total of 100 g. being given. was no evidence of any benefit from the treatmen patient remained mildly febrile throughout, he lost weight, and comparison of radiograms at the begin end of the course showed that, if anything, there h some extension of the infiltration during the period.

Case 5.—A man, aged 22, was admitted on May 17 His admission was regarded as an emergency and was at the special request of a Service hospital where the had arrived gravely ill with acute pneumonic tube His transfer to the sanatorium was effected by air amb and he was so seriously ill on arrival that only the of investigation was possible. He was taken straight the ambulance to the X-ray department, where a film chest was obtained as he lay on the stretcher. He a desperately ill, with high fever up to 105°F each ev heavy sweating, and a severe and racking cough acco by abundant purulent sputum which contained very n tubercle bacilli. His X-ray film showed extensive ex disease in the upper half of the right lung, with ragged of cavitation. The lower three-fifths of the left lun consolidated throughout.

Treatment with streptomycin was begun immediatel a few days later a left phrenic paralysis and pneumoperit were added, because the situation seemed so desperat every possible aid must be utilised. During the succ fortnight there was little change. The temperature re high and the racking cough continued, but there further deterioration in his condition, in contrast to the before admission. Then slowly the tide began to turn. temperature came down gradually to 101° and then to He began to gain weight, the cough improved, and the sp diminished. The radiological appearances, however, rem unaltered, despite the notable improvement in sympton general condition, until July 22, when for the first tin radiogram showed a moderate degree of clearing of the in tion in the right lung and of the consolidation in the

NINGO-ENCEPHALITIS IN MAN DUE TO THE LOUPING-ILL VIRUS

IMPERIAL CHEMICAL (PHARMACEUTICALS) LTD.

UPING-ILL occurs naturally in sheep on hill farms rtain areas of Scotland and the border counties of and, where it is responsible for a considerable ality. Well known to farmers for over a century, it because of its economic importance, been the ect of much discussion and investigation, culminating 30–32 in a series of reports in which its nature and e of transmission were finally established. Pool L (1930), in successful experimental transmission, ed that louping-ill is due to a filter-passing virus, MacLeod and Gordon (1932) established that the p tick (*Ixodes ricinus*) is the natural vector. Further ies on its histopathology and transmission to other als were made by Hurst (1931), Brownlee and on (1932), Gordon et al. (1932), and Findlay and n (1933), from whose communications the following mation on louping-ill in animals is taken.

LOUPING-ILL IN SHEEP

rect infection from sheep to sheep does not occur; ction is conveyed by the tick, *Ixodes ricinus*, which its larval stage becomes infected by sucking the d of an infected sheep, and is itself infective in its phal and adult stages.

hen a sheep is bitten by an infected tick, there is lly an incubation period of one or two days followed a simple febrile reaction lasting three or four days. re is then a short afebrile period, after which the perature again rises and typical symptoms develop. sheep becomes dull and incoördinate, and there are cular tremors, especially of the head, with salivation champing of the jaws. Often the sheep makes leaping ements (hence the name "louping-ill"), and there may ataxia of cerebellar type. Within a period varying n a few hours to one or two days the sheep becomes ble to stand, and it lies, usually on one side, kicking orously. Paresis of one or more limbs may ensue, this stage is succeeded, usually in a few hours, by na and death.

Occasionally the sheep dies in the initial febrile period a septicæmic type of illness and without nervous ns. Other sheep develop only the initial febrile upset then recover completely, being thereafter immune inst further attacks. In examinations of sheep from ms where the disease was prevalent 20% were found be immune, presumably having survived an infection.

There is a second tick-borne infection of sheep, ick-borne fever," which is immunologically distinct m louping-ill, and it is stated that only when the ep already has tick-borne fever does infection with the ping-ill virus lead to the characteristic cerebral illness.

heep may be infected experimentally by inoculation the virus intracerebrally and by other routes. When erimental inoculation is successful, the disease as cribed above follows after an incubation period of or two days. Repeated passage of the virus from ep to sheep by intracerebral inoculation appears to ghten its virulence and shorten the incubation period.

At necropsy of sheep dying of either natural or experimental louping-ill there are no gross changes, but histological examination shows a general meningo-encephalo-myelitis, with varying degrees of damage to the Purkinje cells in the cerebellum and often severe damage to the nerve-cells in the medulla and spinal cord. No inclusion bodies can be seen. The virus can be recovered from the blood of experimentally infected sheep between the third and seventh days after inoculation; after death it can be recovered constantly from the brain, and often from other tissues.

LOUPING-ILL IN OTHER ANIMALS

Though the disease does not appear to occur naturally in other animals, many, including the pig, mouse, field vole and monkey, can be infected experimentally by intracerebral inoculation, and the mouse can be infected also by intranasal instillation. Full accounts of the clinical and pathological findings in the pig, mouse, and monkey are given in the communications already mentioned. Briefly, in all these animals infection leads to a meningo-encephalo-myelitis; the symptoms and the intensity and distribution of the histological changes vary from species to species. Inclusion bodies have been described in the mouse and the monkey.

LOUPING-ILL IN MAN

Rivers and Schwentker (1934) reported in detail illnesses suffered by 4 persons working with the louping-ill virus in the laboratory. Their sera were examined, after recovery, for virus neutralisation by a technique fully described by Rivers and Schwentker. All 4 sera neutralised the virus of louping-ill. Similar tests were made on 46 people with, or recovered from, various illnesses; in only 1 was there any virus neutralisation, and this was incomplete. In 10 other people who had possibly had contact with louping-ill virus these serological tests were negative. Finally, of the sera of 3 persons who had handled the virus but gave no history of illness, 1 neutralised the virus and 2 did not. From these results it was concluded that the test gave reliable evidence as to whether or not a person had been infected with the virus. Consideration of the circumstances under which the 4 people fell ill, and of the features common to their illnesses, led to the conclusion that these illnesses were due to infection with the virus of louping-ill.

Wiebel (1937) and Wesemeier (1938) each reported a further case in a laboratory worker, with serological confirmation of diagnosis, and in Wesemeier's case the result of the serological test was rendered more significant by the observation that a year previously a virus-neutralisation test on the patient's serum had been negative.

In one of the 6 patients the illness would have passed for influenza; in the remaining 5 it took the form of a meningo-encephalitis, and in 3 of these was biphasic, the meningo-encephalitic phase following an "influenzal" phase after several days' comparatively good health. The symptoms and findings included headache, prostration, fever, vomiting, drowsiness, insomnia, photophobia, diplopia, slow speech, vertigo, tremors, ataxia, neck stiffness, bradycardia, and papillœdema. All patients recovered completely in one to three months. The cerebrospinal fluid (C.S.F.) was examined in 4 of the 6 patients; in 1 it was normal, whereas in 3 the protein-level was raised and there was lymphocytosis. The 4 persons reported by Rivers and Schwentker were all engaged in performing intranasal instillations of the virus into mice, and in 1 the onset of symptoms was within eight days of beginning work with the virus.

All 6 reported cases of human louping-ill have been in laboratory workers, and the present cases are the first in which infection is assumed to have been acquired naturally and outside of the laboratory.

hervibora and in man, it has been objected that the cells were really undergoing phagocytosis, and that the huge cells containing about 200 red blood-cells found in the thyroid gland in man (Duran-Jorda 1947) were the result of an unknown mechanism of cellular degeneration (*Lancet* 1947).

It was decided that the point could be proved more conclusively if it was demonstrated with red blood-cells of a characteristic shape, and for this reason the camel was chosen, because it has elliptical red cells. The idea was to demonstrate that the granules contained in the eosinophils of this animal had the same characteristic appearance as the free red cells. The scientific director of the local zoo provided us with the camel blood; and, since the peripheral blood contained a large quantity of eosinophils, the observations were simple. Smears stained with May-Grünwald-Giemsa showed that all the granules contained in the eosinophils were elliptical. They were smaller than those of the horse but larger than those of man, and it was most satisfactory to be able to find this elliptocytosis in the granules both while they were contained in the cell and after they had broken out of the cytoplasm by the action of smearing. The granules in the eosinophils of the peripheral blood (fig. 3) showed a definite range of sizes, but even at their largest they were never so big as those found in the horse. If the granules can grow larger in the cells, one can imagine their expulsion into the circulating blood as perfectly developed red cells.

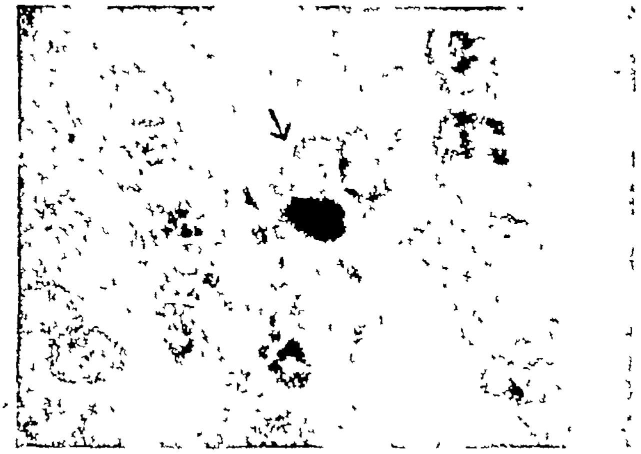

Fig. 2—Gastric mucosa of horse showing eosinophils in situ secreting red blood-cells.

In contrast to the elliptical granules of the eosinophils were the normoblasts, which were round (fig. 4). According to the accepted ideas of blood formation these normoblasts should be denucleated by some unknown process or should undergo either karyorrhexis or expulsion and, in the case of the camel, should afterwards form themselves into elliptocytes, the process laborious that it is difficult to accept. The ell granules of the eosinophils in camel's blood striking contrast to the granules of the basophils, are perfectly circular (fig. 5).

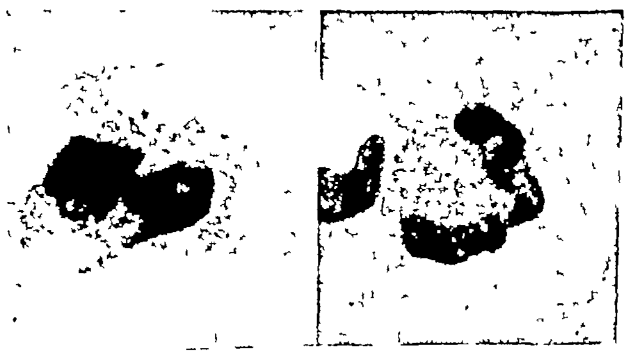

Fig. 3—Camel's blood showing different sizes and elliptical shape of intracellular and extracellular granules.

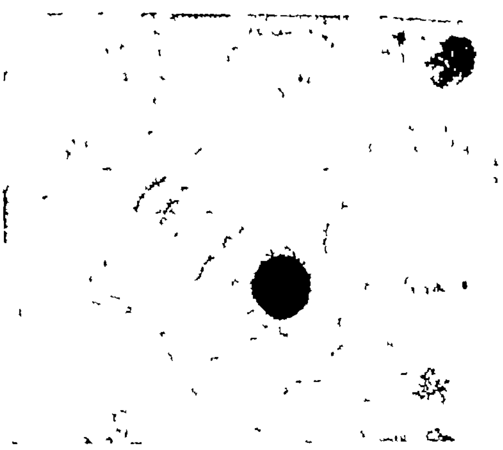

Fig. 4—Normoblast in camel's blood. Note surrounding el red blood-cells.

Owing to the difficulty of obtaining camel t I have not yet had the opportunity of studyi gastric and intestinal mucosa and spleen to find missing link in the complete cycle of blood fo in this animal; but, if such tissues are fortheo should be simple enough to show that the e is the mother cell of the "*mere hæmoglobin* f drops of protein" (Thompson 1942). For hæmat

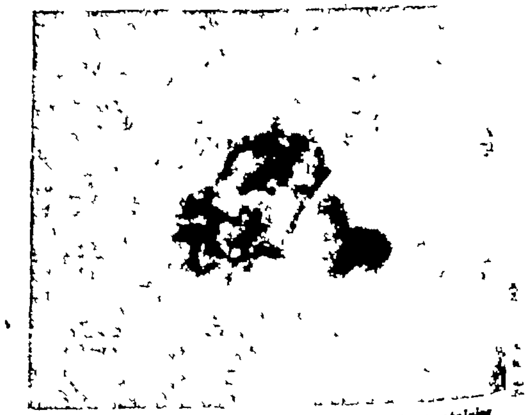

Fig. 5—Camel's blood showing basophil leucocyte containing granules.

who prefer a different interpretation there is the al tive one that the eosinophil is a product of a mo phagocytosis of about 200 red blood-cells whic carefully shrunk until they become eosinophil gr (von Kölliker 1853).

My thanks are due to Dr Leandro Cervera for his siastic interest and helpful suggestions on these pro Inspector Wilfred Taylor, O B S I, for his coöperati supplying veterinary specimens; and Mr. Gerald Ile, logical superintendent of Belle Vue, Manchester, w whose assistance the investigations on camel's blood have been impossible.

ı to affect the central nervous system. The serum atient who had recovered in 1933 from louping-ill positive complement-fixation and neutralisation with the viruses of both louping-ill and Russian -summer encephalitis, as did the serum of a t who had an encephalitic illness while working he two viruses in the laboratory. There is therefore, ling to Casels and Webster, a striking similarity en the two viruses in their clinical effects, modes nsmission, and immunological responses.

SUMMARY

) cases of louping-ill in man are reported, with ıce suggesting that the infection was acquired ılly and not in the laboratory as in previous cases.

: clinical picture of louping-ill in man is that of go-encephalitis, usually following a prodromal ıza-like illness and followed by complete recovery st cases.

s suggested that the illness would be more often osed if it were suspected whenever a meningo-halitis appears in a person exposed to louping-ill

e evidence linking louping-ill with Russian spring-ıer encephalitis is given.

credit for diagnosis in case 1 lies essentially with the ıt, Mr. William Lyle Stewart, of the Department of ılture, King's College, Newcastle-on-Tyne. To him we ıdebted also for a clear history of his symptoms, for e on how the diagnosis could be established, and for s of further information.

nks are also due to Dr. W. S. Walton, medical officer of ı for Newcastle-upon-Tyne, and to Dr. George Hurrell Dr. E. G. Brewis, medical superintendents of the astle General Hospital and the City Hospital for Infec- Diseases respectively, for facilities provided; Dr. R. n and Dr. Emslie Smith for bacteriology; Mr. G. F. otham for neurosurgical advice; Dr. S. Whately dson for radiological reports; Dr. W. H. H. Merivale ochemistry; Dr. Paul Szekely for helping one of us) with translation of the literature; and Dr. T. H. Dr. L. Richmond, and Dr. G. W. L. Kirk for reference patients and information given.

LEONTIASIS OSSIUM

C. BERKELEY WAY

M.C., M.B. Lond.

EDICAL OFFICER, HENDON COTTAGE HOSPITAL, LONDON

ITH the improvements that have taken place in istry and in the surgery of the nasal accessory sinuses, s of leontiasis ossium should become rare. The skull ı the case reported here has been accepted by the eum of the Royal College of Surgeons.

e patient was a spinster, who died in 1944 at the age of Her appearance and health were normal until the age), when she had a bicuspid tooth stopped. She had no , but a few months afterwards a hard swelling developed e gum above the tooth, followed later by similar changes he cheek. Much dental treatment followed, but the ling steadily increased, spreading to the other cheek and the frontal region. Beyond occasional headaches the ition caused her no physical or social inconvenience. was a charming, witty, and well-beloved lady who inued her work as a book-keeper until four months before death, with only one short period of ill health.

In 1939 she had a transient hemiplegia: blood-pressure 220/95 mm. Hg; left knee-jerk exaggerated and left plantar reflex extensor; otherwise no physical signs. She was working again in six weeks, the left knee-jerk remaining slightly greater than the right and the left plantar reflex indefinite until her death. The B.P. continued high, and there was some cardiac enlargement. Four months before her death she left her office well, but later was found crawling up the stairs to her flat. From then onwards muscular control slowly left her; deafness, which had not been present before, became intense; and her mental faculties were much slowed. However, if one could wait, she would eventually provide a witty and appropriate answer to a question. Swallowing became difficult, hypostatic congestion supervened, and she died in coma.

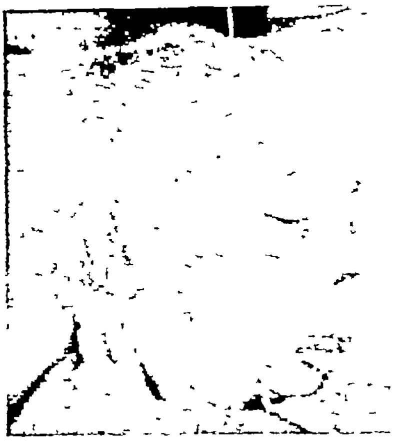

Fig. 1—"Lion-like" head of patient with leontiasis ossium.

Her nares and intranasal spaces were wide, but there was no crusting. She never had a cold. Her ear drums were normal. Bone conduction was lost. Her mandible was not unduly small in comparison with her sister's. Radiogram of the pelvis was normal. For the condition of the skull see figs. 1 and 2.

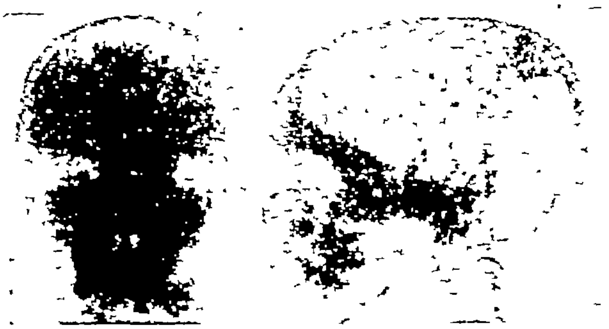

Fig. 2—Anteroposterior and lateral radiograms of skull.

COMMENTS

In view of the hyperpiesia, it can be fairly said that the condition caused little inconvenience to her health and was only slightly contributory to her death.

The history appears to follow the usual lines in that a chronic septic osteoperiostitis follows a sinus infection and one by one the accessory air chambers are filled with masses of inflammatory cancellous bone protruding outwards and causing great disfigurement. Bony changes spread to the skull (cancellous hyperostosis of Virchow); the mandible sometimes is involved, but the base of the skull usually escapes. In the present case, however, the base is involved and the mandible is normal. The lion-like head is well depicted in the photograph. The absence of colds and the dryness of the nose suggest that the mucosa lining the sinuses is the major source of nasal secretion.

". . . Can there be values greater than the mere attainment of health? One reason why we have not been more successful in directing people toward healthful living is that subconsciously many have decided, and quite correctly, that there are more important things than merely being healthy." —W. W. BAUER, M.D., director, bureau of health education, American Medical Association, in Motivation in Health Education. London, 1948; p. 20.

virus of louping-ill. In case 1 the presumption is that the recent severe nervous illness represented this infection. In case 2 evidence for connecting the recent nervous symptoms with infection by the virus is rather stronger, inasmuch as the neutralising properties of the serum had apparently increased in the interval between the first and second bleedings.

"The serum of case 2 did not neutralise the virus of lymphocytic choriomeningitis. It did, however, possess neutralising power against the virus of herpes febrilis, a not uncommon property of human sera."

COMMENTS ON CASES

Dr. Hurst's findings show that case 1 had passed through an infection with the louping-ill virus before October, 1945. The symptoms described conform closely to those previously reported for cases of louping-ill in man. Moreover, case 1 had previously had no illness, however slight, which could have been attributed to louping-ill infection. There are therefore good grounds for assuming that the present illness was the result of infection with the louping-ill virus.

The descriptions of the other human cases are compatible with an incubation period of a few days, comparable with the incubation period in animals, naturally or experimentally infected. Case 1 had had no laboratory contact with the virus for several months, but, within a few days of the onset of his illness, he had been infested with *Ixodes ricinus* from sheep in an area where louping-ill occurs. It seems reasonable to conclude that his present illness was the result of infection transmitted by the tick bite.

In case 2 the evidence that the present illness was louping-ill naturally acquired is even more conclusive. Again there was no history of any previous illness which could have been attributed to the louping-ill virus, and an apparent rise of the protective power of the serum during the illness suggests that the tests were made during the period of infection. Laboratory infection can be excluded. The illness differs from that in any previously reported case in its severity and in the probability that the patient will be left with permanent sequelæ. This may be linked with the observation that the C.S.F. showed a continued pleocytosis and increase in globulin for at least two months and a paretic Lange curve after eleven weeks. Case 2 did not contract the illness until he was 59, though he must have been exposed to the risk of infection for many years. Perhaps poor health, as shown by the loss of energy, appetite, and weight for some months previously, had increased his susceptibility to infection.

DISCUSSION

Louping-ill in man bears comparison with other virus infections of the central nervous system, such as poliomyelitis, and with the illness in animals. The illness in man and in the sheep show many points of resemblance such as the biphasic character, meningeal reaction, and cerebellar signs. The fact that cases of louping-ill in man other than those infected in the laboratory have not previously been recorded is probably due to failure of diagnosis rather than lack of cases. The diagnosis might well be made more often were the clinical picture more widely known.

The clinical picture of louping-ill in man is probably as variable as that of poliomyelitis. It is now known that the classical picture of paralytic poliomyelitis is one of the less common manifestations of the infection, which is often followed by only a mild non-specific illness with rapid recovery; the same may be true of louping-ill. Nevertheless, recognition of louping-ill will depend primarily on recognition of the cerebral type of illness. It is therefore justifiable to try to paint this picture in the light of the limited number of cases so far recognised.

A few days after laboratory exposure to the virus, or after tick bite in an endemic area, the illness begins with malaise, headache, and fever, which continue for a week. There is then an afebrile interval of one or weeks, during which the patient gradually recovers may return to work. The symptoms now return increased intensity—severe headache with fever, bradycardia, drowsiness, insomnia, confusion, and sibly tremors and ataxia. Physical signs are r few but may include neck stiffness, papillœdema, cranial-nerve palsies. The fever abates in a few and the symptoms have largely cleared in a a few weeks elapse before the patient feels fully re During the second phase the blood shows a mild cytosis of 10,000–12,000 per c.mm., with 7 neutrophils. Lumbar puncture yields a clear or blood-stained fluid, with a normal or slightly protein content and a pleocytosis of 50–500 cells c.mm., predominantly lymphocytes.

Variations of this picture so far known are t illness may be mild, ending with the first phase without development of meningo-encephalitis; or first phase may be wanting and the second phase severe, with widespread cerebral involvement tremors, ataxia, and pyramidal signs, and lead permanent sequelæ. The cells in the C.S.F. may be polymorphs.

The disease should be suspected whenever encephalitis develops in a person exposed to the ill virus either in the laboratory or by contact sheep ticks in one of the endemic areas, espec the summer. The diagnosis may be confirmed by neutralisation tests properly carried out and int by an expert. A diagnosis might be made by inoculation of blood removed at the onset of the but it is extremely unlikely that the diagnosis be considered at that stage.

In case 1, when papillœdema was found, espec view of the bradycardia and increasing symp cerebral tumour or abscess was suspected, th primary focus for an abscess was found. The were searched to find if the tumour excised from a seven years previously might have been of a type could metastasise later to the brain, but it pro have been benign. Finally, as recovery ensued, encephalitis of unknown origin was diagnosed, was the patient who offered the diagnosis which ultimately accepted. In case 2 the clinical and findings led to the diagnosis of a virus infection central nervous system, and consideration of his tion and of the area from which he came promoted investigation of his serum.

The relationship of louping-ill to Russian spring-su encephalitis remains to be considered. The work on this disease in Russia in 1937–39 has summarised by Somorodintsev (1944). The illness describes shows striking resemblances to louping-ill is a virus disease transmitted by *Ixodes persulcatus* is transmissible to monkeys, goats, sheep, and and other rodents. It is believed that birds and ro act as a natural reservoir. In man infection prod a severe meningo-encephalitis, with a mortality 20–30%, and with frequent residual paralyses. Whe louping-ill is seen commonly in sheep and uncomm in man, Russian spring-summer encephalitis is com in man; in each case the mortality is high in the commonly affected. Russian spring-summer enceph differs from louping-ill in the incidence of resid paralyses. Casals and Webster (1943, 1944) have stu the viruses of louping-ill and Russian spring-sum encephalitis in relation to other viruses which affect t central nervous system. They have found, by comp ment-fixation, neutralisation, and cross-resistance t on susceptible animals, a very close relationship the viruses of louping-ill and of Russian spring- encephalitis, but no relationship with any other

Dietary Fat

E vociferous demand for a larger fat ration, h has been heard in Germany since the capitula- has lately been echoed in this country. As WALKER points out on page 476, BICKNELL ves that our present intake—which is about daily—is hopelessly deficient. and Lord WOOLTON rds the deficiency as dangerous. What is the nce for deficiency? The German claim, which been voiced insistently by Professor REIN in the ngen *Universitätszeitung*, evoked a request for nce that the very low intake is causing or has ed ill health. None has been forthcoming. year German doctors received a printed post- purporting to give *minimum* dietary fat require- s as laid down by experts. The figures were: (Paris, 1941); 100 g. (London, 1945); 20–35% tal calories (U.S.A., 1944); and 80–125 g. (League ations, 1938). The Paris reference is to a lecture Mme RANDOIN,[1] who suggested that animal fat ut 10 g. daily) was required to provide vitamins A D and part of the vitamin E, and vegetable about 30 g. daily) for the rest of the vitamin E for unsaturated fatty acids. The reference London, 1945, was to Starling's *Principles of an Physiology*, which quotes the British Medical ciation report of 1933. This report merely says "One hundred grams of fat per day is usually pted as an adequate quantity"—hardly scientific ence. In 1944 a committee of the United States onal Research Council, in defining a "tentative toward which to aim in planning practical ries," remarked that "There is available little mation concerning the human requirement of Fat allowances must be based at present more food habits than on physiological requirements. . It is desirable that fat be included in the diet he extent of at least 20–25% of the total calories" statement of the Technical Commission on ition of the League of Nations (1938) reads as ws:

> "The minimum quantity of fat or fatty substances hich should be present in the diet is not known. . . . he minimum quantity of fat cannot . . . be established absolute terms. . . . In countries with a temperate imate . . . the fat intake cannot . . . be very low ithout leading to under-nutrition since the result is kely to be an inadequate energy intake. . . . Feasible etary limits might be defined as approximately –125 grams of fat for a varied diet of 3000 calories."

ill be seen therefore that the authorities quoted stating not minimum dietary requirements based on scientific evidence but preferences based largely on guesses.

The craving for fat probably arises for four reasons. First, since fat is absorbed slowly from the gut and slows emptying of the stomach, it has a "satiety value" in delaying hunger between meals. Secondly, food containing fat is easier to eat because of its "lubricating" effect. Thirdly, since fat has more than double the calorie value of other aliments, and since most non-fat foods contain a much higher proportion of water, diets can be less bulky if their fat content is high. (In Germany this may be important for heavy workers but not for normal consumers.) Fourthly, fats are less subject than carbohydrates to fermentation in the gut. At the same time the craving may have an unrecognised physiological origin. Fat can be made from carbohydrate in the body, as many obese people know to their cost. It is not necessary in the diet as a source of the known fat-soluble vitamins, for there is no sound evidence that adult man must have vitamin D for full health, and he gets carotenoids in vegetables, calcium and phosphorus in bread and water, and vitamin E —which he may not need at all—in bread. In young rats, deficiency of essential fatty acids causes cessation of growth, eczema, scaliness of feet and tail, hæmaturia, and death; in dogs eczema develops. There is no proof that unsaturated fatty acids (linoleic, linolenic, and arachidonic) are necessary for health in man, though they probably are. Two different workers have produced eczema in infants kept on diets extremely low in fat; but, on the other hand, BROWN[2] lived for six months on a daily diet containing less than 0·03 g. of fat per kg. of body-weight and observed no ill effects. There is some evidence that a high-fat, low-carbohydrate diet reduces susceptibility to acute respiratory infections, but BROWN showed no increase in susceptibility. Six months in the life of man corresponds to about a week in the rat's life, and rats on the same diet showed signs of deficiency only after a proportionately much longer time: so it is quite possible that if BROWN had continued his diet for longer ill-effects would have been observed.

If we concede that man needs small amounts of certain fatty acids, we still cannot conclude that 60 g. of fat daily is "hopelessly deficient"; bread of high extraction, such as we consume today, probably contains sufficient unsaturated fatty acids to fulfil our physiological requirements. However, if the amount of fat in the diet falls very low, calorie deficiency may result, because the intestine of man is not well adapted to a bulky carbohydrate diet, and this lack of calories may cause famine œdema—which partly explains why fat deficiency is often regarded as an important cause of famine œdema. Cases of famine œdema have lately been divided into two classes[3]: those with low plasma protein so that the diminished colloidal osmotic pressure causes water to pass into the tissues; and those in which the plasma protein is within the normal range and there is probably increased reabsorption of water in the kidney tubules. The great majority of cases seen on the

Reviews of Books

Acute Intestinal Obstruction

RODNEY SMITH, M.S., F.R.C.S., assistant surgeon, St. George's Hospital, London. London: E. Arnold. 1948. Pp. 259. 18*s.*

GREATER knowledge of the pathology of acute intestinal obstruction has led to much improvement in the results of treatment. This monograph is a timely exposition of the subject. Mr. Smith discusses the pathology, diagnosis, and treatment of acute obstruction and gives an account of the technique of treatment by intubation, and of the nature of the changes in body fluids caused by stoppage of the bowels. A well-illustrated description of the use of radiology in diagnosis is contributed by Dr. Eric Samuel. Every known cause of obstruction, from the level of the pylorus to the anus, is covered, and the book is a reference work which can be well recommended to all surgeons.

Eat and be Healthy

Diets and Nutrition in Ceylon. LUCIUS NICHOLLS, C.M.G., M.D. Camb., sometime director of the Ceylon Bacteriological Institute. Colombo: Associated Newspapers of Ceylon. 1947. Pp. 69. 5*s.* 8*d.*

ALL those who have come across Dr. Nicholls's work on nutrition in Ceylon will be keen to see his synthesis of the subject of diet and will look forward to reading this book. They will not be disappointed. Though, or perhaps because, he has adopted a simple style, his words often have dramatic power. For example: "Some classes of Mohammedan women in Egypt and India practise strict purdah, whereby they spend their lives in closely guarded dwellings; many of these women cannot afford milk, butter, or ghee. Ignorant of the values of fish-liver oil, they become afflicted with osteomalacia, and may become so deformed that they are unable to give birth to a child—pregnancy means death to them." It must not be thought that this book is useful only to the Sinhalese, or to governors and governed in tropical countries. It is also important to those who live in more temperate climates. The diets of native races which are strange to us often throw light on our own dietary problems, as witness the works of Stefánsson on the Eskimos and of Orr and Gilks on the Kikuyu and the Masai, not to mention more recent work by Professor Platt. The problem of nutrition is the same all over the world, though the local solutions may be different.

Principles of Occupational Therapy

Editors HELEN S. WILLARD, B.A., O.T.R., director of the Philadelphia School of Occupational Therapy; CLARE S. SPACKMAN, B.S., M.S. in ED., O.T.R., director of the occupational therapy department, University of Pennsylvania Graduate School of Medicine Hospital. Philadelphia and London: J. B. Lippincott. 1947. Pp. 416. 25*s.*

THE technique of occupational therapy has a growing literature, but far too little attention has been directed towards the underlying principles. How often one hears occupational therapy described as being either diversionary or remedial in purpose, as if that were all. Actually, it has many more important functions: it can be employed as a valuable aid to diagnosis, in the investigation of neuroses and psychoses; it can help to determine activity tolerance, in the treatment of chronic medical disorders; it can help in the restoration of physical and nervous function, imperilled by severe illness or injury; it can provide a useful stimulus to the creative faculty, for patients confined to long periods of inactivity, and help to counter the obsessional anxiety and antisocial tendency of the psychologically disturbed; and it can actually form part of the prevocational testing and vocational training of those who need to change their employment because of serious and permanent disability. The methods by which these uses can be served in different medical and surgical disorders, in the treatment of mental disease, and in the reablement and education of crippled children, of the blind, the tuberculous, and the arthritic, are well described in this volume, though it is more strictly a handbook of occupational therapy than a treatise on principles. Valuable hints are given on the right way to approach a ("try to untanglo his fears and provide him with tives"), on the best methods of instruction, and on types of occupational therapy suited to various diso

The book is almost confined to occupational th as taught and practised in the United States, where appears, there are now 21 schools, almost all conn with university medical centres, and an average 1750 new students each year, each of whom t university course or is already a graduate. Pro because of their preoccupation with American me the authors do not refer to the incorporation of oc tional therapy in industry itself, as carried out so su fully in Birmingham and Luton; to the use o therapy, as in the British Red Cross Picture L scheme; or to Mr. John Colson's valuable book occupational-therapy technique.

Juvenile Delinquency in an English Middletown

HERMANN MANNHEIM, reader in criminology, Uni of London. London: Routledge and Kegan Paul Pp. 120. 12*s.* 6*d.*

Dr. Mannheim has turned to advantage the w evacuation of his university department to Camb though his choice of title may seem a little damp those who consider Cambridge atypical. The follows on the important "Cambridge Evac Survey," and is an ecological study of the records pre-war and 123 war-time delinquent boys pl probation or under supervision. True to modern tical tradition, the author is a severe critic of his material: the records are incomplete, compiled by agencies and with no thought of a possible value; numbers are few and there is no control and anyway, statistics based on court cases are intimately related to the quality of the local activity than that of the delinquent child. Such backs have deterred less determined investigato the work is painstakingly done and (except that of 10 or less are reduced to percentages) is a sound lesson in method for the research student.

The principal findings, as might be expected from material, are cautious and modest, useful for com with other studies and as confirmation rather original. The recommendations are wise and fars but derive more from the author's vast experience from the present study. Dr. Mannheim does not tively answer by this study critics of *Young O* who held that, in this field, there is little fut the method of statistical investigation and th urgent need is still for individual inquiry into psychodynamics of delinquency.

The Report of the ROYAL SOCIETY EMPIRE SCIE CONFERENCE, held in June-July, 1946, has now been pub Besides the papers given at the conference the two vol contain reports of the discussions, the recommend made, and accounts of the origin and conduct of the conf and of the opening ceremony. (Edinburgh: Printed fo Royal Society by Morrison & Gibb. 1948. Pp. 828 and Two vols. 42*s.*)

Taylor's Principles and Practice of Medical Ju prudence (10th ed. Vol. I. London: J. & A. Chu 1948. Pp. 723. 45*s.*).—Few reference books can claim reputation that "Taylor" has maintained in both and Scottish courts since the first edition appeared in this first volume of the 10th edition has been revised broad scale. Prof. Sydney Smith has moulded these volumes for some 20 years, wisely retaining much of Ta original discursive style and shrewd observation, while re scientific method and the ever-changing statutory la conformity with the march of time. The authority of the is beyond question and no review profits by a fine co for gaps in the setting of such a vast field. Much new mat —including innumerable case-reports—has been added care and judgment. The only major mishap in productio an example of the adage that textbooks are always out of da the Workmen's Compensation Acts were superseded on Jul by the National Insurance (Industrial Injuries) Act of 1 and the Law Reform (Personal Injuries) Act, 1948. The b is sound, comprehensive, couched in a fine literary style forthright English, and displays unassailable judgment.

Dietary Fat

E vociferous demand for a larger fat ration, has been heard in Germany since the capitula- has lately been echoed in this country. As Walker points out on page 476, Bicknell res that our present intake—which is about daily—is hopelessly deficient, and Lord Woolton ds the deficiency as dangerous. What is the nce for deficiency? The German claim, which een voiced insistently by Professor Rein in the ngen *Universitätszeitung*, evoked a request for nce that the very low intake is causing or has d ill health. None has been forthcoming. year German doctors received a printed post- purporting to give *minimum* dietary fat require- s as laid down by experts. The figures were: (Paris, 1941); 100 g. (London, 1945); 20–35% tal calories (U.S.A., 1944); and 80–125 g. (League ations, 1938). The Paris reference is to a lecture Mme Randoin,[1] who suggested that animal fat ut 10 g. daily) was required to provide vitamins A D and part of the vitamin E, and vegetable (about 30 g. daily) for the rest of the vitamin E for unsaturated fatty acids. The reference London, 1945, was to Starling's *Principles of an Physiology*, which quotes the British Medical ciation report of 1933. This report merely says "One hundred grams of fat per day is usually pted as an adequate quantity"—hardly scientific ence. In 1944 a committee of the United States ional Research Council, in defining a "tentative toward which to aim in planning practical aries," remarked that "There is available little mation concerning the human requirement of Fat allowances must be based at present more food habits than on physiological requirements. . It is desirable that fat be included in the diet he extent of at least 20–25% of the total calories" statement of the Technical Commission on trition of the League of Nations (1938) reads as ows:

> "The minimum quantity of fat or fatty substances hich should be present in the diet is not known. . . . he minimum quantity of fat cannot . . . be established absolute terms. . . . In countries with a temperate limate . . . the fat intake cannot . . . be very low ithout leading to under-nutrition since the result is kely to be an inadequate energy intake. . . . Feasible ietary limits might be defined as approximately 0–125 grams of fat for a varied diet of 3000 calories."

will be seen therefore that the authorities quoted stating not minimum dietary requirements based on scientific evidence but preferences based largely on guesses.

The craving for fat probably arises for four reasons. First, since fat is absorbed slowly from the gut and slows emptying of the stomach, it has a "satiety value" in delaying hunger between meals. Secondly, food containing fat is easier to eat because of its "lubricating" effect. Thirdly, since fat has more than double the calorie value of other aliments, and since most non-fat foods contain a much higher proportion of water, diets can be less bulky if their fat content is high. (In Germany this may be important for heavy workers but not for normal consumers.) Fourthly, fats are less subject than carbohydrates to fermentation in the gut. At the same time the craving may have an unrecognised physiological origin. Fat can be made from carbohydrate in the body, as many obese people know to their cost. It is not necessary in the diet as a source of the known fat-soluble vitamins, for there is no sound evidence that adult man must have vitamin D for full health, and he gets carotenoids in vegetables, calcium and phosphorus in bread and water, and vitamin E —which he may not need at all—in bread. In young rats, deficiency of essential fatty acids causes cessation of growth, eczema, scaliness of feet and tail, hæmaturia, and death; in dogs eczema develops. There is no proof that unsaturated fatty acids (linoleic, linolenic, and arachidonic) are necessary for health in man, though they probably are. Two different workers have produced eczema in infants kept on diets extremely low in fat; but, on the other hand, Brown[2] lived for six months on a daily diet containing less than 0·03 g. of fat per kg. of body-weight and observed no ill effects. There is some evidence that a high-fat, low-carbohydrate diet reduces susceptibility to acute respiratory infections, but Brown showed no increase in susceptibility. Six months in the life of man corresponds to about a week in the rat's life, and rats on the same diet showed signs of deficiency only after a proportionately much longer time; so it is quite possible that if Brown had continued his diet for longer ill-effects would have been observed.

If we concede that man needs small amounts of certain fatty acids, we still cannot conclude that 60 g. of fat daily is "hopelessly deficient"; bread of high extraction, such as we consume today, probably contains sufficient unsaturated fatty acids to fulfil our physiological requirements. However, if the amount of fat in the diet falls very low, calorie deficiency may result, because the intestine of man is not well adapted to a bulky carbohydrate diet, and this lack of calories may cause famine œdema— which partly explains why fat deficiency is often regarded as an important cause of famine œdema. Cases of famine œdema have lately been divided into two classes[3]: those with low plasma protein so that the diminished colloidal osmotic pressure causes water to pass into the tissues; and those in which the plasma protein is within the normal range and there is probably increased reabsorption of water in the kidney tubules. The great majority of cases seen on the

Continent in the last three years have been of the latter type; and there is no evidence that in these the œdema is caused by fat deficiency.

Provided sufficient calories can be made up from other sources, then, fat in the diet is desirable but probably not essential. Unfortunately, throughout the world foods rich in fats are even scarcer than most other nutritional commodities. This shortage will partly be overcome by the African groundnuts scheme, which might be supplemented by the use of synthetic fats. Research on these was conducted in Germany during the war, and a plant for their commercial production was established at Witten, where fuel was made by the Fischer-Tropsch process from carbon monoxide and steam; a byproduct from this process was "gatsch," which consisted of soft paraffins from which edible synthetic fats could be made. These were tested by some distinguished physiologists in Germany, including **Karl Thomas**, and were used in feeding the armed forces: the Witten plant could produce some 18,000 tons of synthetic fats annually, from which about 7200 tons of margarine could be produced. Further research should be done on this subject. For the present we must consider ourselves lucky in this country to have a relatively luxurious amount of fat in our diet, and it is not surprising that no scientific evidence has been forthcoming of any harm from shortage. It remains possible that the increased palatability and variety afforded by additional fat would improve the nutrition of our workers and promote production. Of this we know very little and need to know more.

Supplies of Radioactive Isotopes

Few medical research-workers in this country have yet been able to use radioactive isotopes for tracer studies and there have been no supplies for treatment. Almost all our knowledge of their therapeutic actions and of the application of tracers to medical and physiological problems has so far come from America. But in a statement published on page 469 the Medical Research Council announce that they can now obtain limited quantities of isotopes for approved tracer and therapeutic projects in this country, and regular supplies are expected soon from Canada and later from the British atomic plants, when completed.

The emphasis on tracer research rather than on treatment reflects the American experience, which has on the whole been disappointing in the clinical field. Radiophosphorus (P^{32}), for example, has been extensively tried for the treatment of leukæmias, polycythæmia vera, and Hodgkin's disease; its use is now limited to chronic myeloid leukæmia and polycythæmia. **Lawrence** and his associates,[1] reviewing the results in 129 cases of chronic myeloid leukæmia treated with radiophosphorus, note that only 33 survived five or more years after the onset of symptoms and the average length of life was 3·7 years. These figures are of the same order as those obtained with X-ray treatment, and radiophosphorus therapy is much more difficult to control owing to the ever-present danger of inducing aplastic anæmia and the need for wide variation in dosage in different patients. Polycythæmia patients have vived much longer and had longer remissions, this accords with the natural history of the and equally good results have been seen with body irradiation or even with periodic A new hazard that has appeared with radio is that it may induce malignancy or even leukæmia, though **Lawrence** did not think that dosage in any of his patients had approached level at which such lesions were induced in mice, none of his patients who had survived five showed any of these changes. The Medical R Council's suggestion that radiophosphorus should be given to patients whose expectation of life is five years seems hardly workable, since at the diagnosis there is no way of distinguishing minority of chronic myeloid leukæmia patients will survive so long, or of finding out which polycythæmia are of the very slowly pro type. Opinion on the value of radioactive hyperthyroidism has not yet crystallised, but again long survival is surely the aim. It is in malignant diseases that radioactive isotopes prove most useful; the council mention cobalt, and there is an important field for trial in use of colloidal gold (Au^{198}) for the loc infiltration of tumours.[2]

Radiophosphorus will cost about 10*s*. and iodine about £1 per millicurie. This means will cost £1–2 for the initial course of tre chronic myeloid leukæmia, and then from 5*s* a week for maintenance. The radio-iodine for of hyperthyroidism will cost £40–50 with p ideas of dosage. Under the National Health the cost will be a Government concern, but it is theless interesting as one of the factors that compared with other treatments giving comp results. For the treatment of leukæmia, therapy costs at least as much and nitrogen somewhat less. For hyperthyroidism, thiouracil much less; the cost of surgical treatment is to estimate, but when the time in hospital is sidered it is probably of the same order as radio treatment.

No-one should imagine that because a rad tracer will help to solve his own particular puzzle can go straight ahead and count on supplies from the necessity of obtaining proper apparatus detecting and handling these materials, two of council's conditions should be specially noted—th physicist must collaborate in the research; and th proper safety measures must be taken. The need a physicist is easy to understand, for the calculati and the apparatus used in this type of work are q outside the medical field. But how many would users of radioactive isotopes realise what is invol in the provision of effective safety measures? avoid over-exposure of workers, the simplest acti like opening a bottle and filling a pipette have all be thought out afresh and carried out by rem control so that the worker is protected by suita screens at every stage. An open beaker contain 5 millicuries of P^{32}, in the form of Na_2HPO_4, radiat 4r per hour 5 inches over the top, 1·2r per hour contact through the bottom, and 0·06r per ho

---

[1] Lawrence, J. H., Dobson, R. L., Low-Beer, B. V. A., Brown, B. R. *J. Amer. med. Ass.* 1948, 136, 672.

hes from the sides. A tenth of a millilitre of a
ion of radiostrontium (Sr^{89}) of 125 microcurie
ity radiated a tolerance dose (0·1r) in 3 minutes
inches. the normal working distance with a micro-
tte. Tompkins,[3] who gives these figures, shows in
ll-illustrated article the minimum requirements
voiding accidents. As he rightly says, " practice
patience will be required to develop the new
ual dexterity and the new ways for conducting
ratory work that are needed." In addition to
e complications, special measures have to be
n to avoid contamination of clothing, to control
osal of wastes, and to "monitor" by special
ces workers and their instruments for excessive
oactivity. When all this is realised, tracer
arch is likely to be restricted to the larger insti-
ons which can afford the space and financial
ay for special laboratories in which this work,
this work alone, will be done, with the help of
ialists trained to handle these potentially dan-
us materials.[4] It is to be hoped that the necessary
lities for using the new supplies will be provided,
that British workers will have their chance to
lore the tremendous field of experiment now
ned to them.

Health Care

k their new-found preoccupation with social
licine doctors know well enough that they
ng to the social-welfare team; but some are
haps not so sure of their place on the field or the
ction of the goal. The principal cause of this
ertainty is the artificial isolation of one member
m another. The evils of this isolation are under-
ed in a report by Dr. John B. Grant,[5] who lately
dertook for the Rockefeller Foundation a tour of
elve countries in North America, Europe, and
stralasia, to assess and compare progress in
ealth care"—a term to which he gives a wider
aning than medical care. The same pattern is
olving in each country, though in some it is more
nplete than in others. Grant divides the evolution
social welfare into three stages. First comes the
ge of paternalistic legislation, developed in Britain
century and a half ago, with the aim, based on
manitarian motives, of relieving outstanding ills;
countries have emerged from this stage. The
cond is the stage of social insurance, intended to
ovide security for labour by pooling risks;
rmany initiated this some sixty years ago and most
untries are now in it. The third stage is based
uarely on a population policy which aims to
prove the quality of human capital by removing
cial ills.

The funds set aside for social security vary widely
om one nation to another. Thus the British social-
surance costs for this year will be at least 10% of
e national income; and the South African estimate
r 1955 is 15%. On the other hand, in the U.S.A.
1946 federal expenditure on social welfare con-
ituted only 1·3% of the national income. There is
ss discrepancy between the nations in their policies
r housing and nutrition, which reflect growing concern with population needs. Formerly housing policy was based on rental returns, but, except in North America and Holland, this basis has been superseded by various types of State subsidy to ensure that rentals do not exceed 20% of the wage-earner's income—a limitation which, without outside help, would render the construction of houses for letting uneconomic. Similarly, in the matter of food almost every European country is establishing a policy akin to that in Great Britain, including free or subsidised protective foods, enrichment of certain foods, free school lunches, price control backed by subsidies, and increased production of essential foods.

If medical care is to take its proper place in the changing order, three conditions must be met: removal of economic barriers; provision of sufficient personnel and resources, properly distributed; and technical excellence in medical personnel and equipment. Economic barriers are almost everywhere being brought down; the only two countries where voluntary insurance still receives consideration are the U.S.A and, to some extent, Denmark. In organisation other countries, including the U.S.A., seem likely to follow the regional plan introduced in Britain; and usually such plans are formulated with an eye to achieving eventually 15 hospital beds per 1000 population. The Hospital Council of Greater New York[6] sets the figure at 16·1, which would be divided as follows: general care 4·2 (residents 4·0, non-residents 0·2), convalescent care 1·0, long-term illnesses 2·0, acute infectious diseases 0·1, tuberculosis 0·8, and psychiatric disorders 8·0. Grant calls for greater initiative outside the hospital; nowhere, he says, is there a health centre fulfilling all the functions envisaged for this institution. The generous provision of hospital beds and of practitioners (1 to 1500 population) which he mentions may not be immediately attainable here. We can, however, take to heart his criticisms of planning in the countries he visited. The most serious is the complete failure, except in Australia, to consider the number, and the training of personnel required to work the organisation evoked by legislation. Secondly, except in South Africa, planning and legislation are for sickness rather than health. Thirdly, not enough regard is paid to chronic, mental, and rehabilitative services. Planning, he contends, has gone ahead in watertight compartments; and there is complete disregard of the need for auxiliary personnel. From his survey Grant concludes that "effective measures for health promotion, disease prevention, and rehabilitation require government action and cannot be attained through voluntary agencies." It is becoming increasingly clear that this is also true of curative medicine.

Annotations

THE INDUSTRIAL CONGRESS OPENS

In the early days of the Industrial Revolution machines were more valued than the men who drove them; and it has taken us some time, as Mr. T. E. A. Stowell remarked at the opening session of the International Congress on Industrial Medicine, to realise the importance of conserving the industrial worker. Mr. G. A. Isaacs, Minister of Labour and National Service, mentioned that it is the Government's policy to set up a national industrial health service, coordinated with the National Health Service, as soon as there are enough trained doctors and auxiliary staff to work it. Reviewing some stages in the growth of our industrial medical service, he recalled that Dr. Thomas Legge, the first medical inspector of factories, was appointed just 50 years ago, and was knighted for his success in proposing measures to counteract risks in industry, especially lead poisoning. Other countries have contributed important studies: South Africa, for example, has led in the study of silicosis. For thirty years the Industrial Health Research Board has been issuing important statistics which are ultimately translated into legal requirements and regulations benefiting health. Progress often seems slow; Mr. Isaacs has found it so, he said; but the ground is well prepared, and in the end we get good regulations and enforce them. That the rut of habitual thought may lock the wheel of progress for an unconscionable time, however, was nicely exemplified by Lord Moran's story of a former Minister. Long before the late war the I.H.R.B. had collected figures relating production to hours of work—which were ignored when the pinch came. Yet when Lord Moran handed the harrassed Minister the proof that a man can produce more in 6 days than 7, he only provoked the indignant response: "Don't you know there's a war on?"

But there are more reasons for a falling off in output than unduly long hours of work; and Lord Moran was glad, he said, to see the changing conception of industrial medicine. Nowadays it is concerned not merely with the physical hazards of industry but with the mental and emotional hazards as well—with the proper study of mankind, in short. What makes a man stick to his job? "Work or want" has fortunately gone, in this country and for this time, as an incentive. What takes its place? What industrial medical officer, he asked, is going to write an *Anatomy of Contentment*? If a man is contented his production is high, and efficient production means social security. As Dr. Lloyd Davies urges on p. 465, we must no longer think of work in terms of whether it is harmful but whether it is beneficial to free men with unfettered minds. The secret of a contented mind may be to do a job well.

A PIPERAZINE ANTHELMINTIC

To the growing list of anthelmintics has now been added a piperazine derivative. Formerly the piperazines were administered as urate solvents, and their reintroduction follows the observation that some derivatives were effective against the filarial parasite of the cotton-rat. Of more than 1000 compounds tested by the Lederle Laboratories the one which was most effective and least toxic was 1-diethylcarbamyl-4-methylpiperazine, known more briefly as 'Hetrazan' diethylcarbamazine.

Extensive trials of hetrazan have confirmed that, with a few hundred milligrammes by mouth in divided doses over a period of 3–7 days, *Wuchereria bancrofti* quickly disappears from the blood-stream. It usually reappears a few days after the drug is discontinued; but in patients receiving similar courses lasting altogether 3–4 weeks the parasite has sometimes remained a for about a year. From the U.S.A. have come suggesting that the drug may cure bancrofti inf by killing the adult worm. In any event, the admi tion of hetrazan for short periods is so effective in the peripheral blood of microfilariæ as to suggest possibility of breaking the filarial cycle at the between man and mosquito, for man is the only known Against other filarial infections of man this prep seems to be less effective; but trials are not yet com As often happens with new drugs, there has been trouble with toxicity. Patients receiving hetrazan not confined to bed; and their chief complaints been of headache, lassitude, and vague malaise. symptoms come on within a few hours of the treat being started, but usually disappear within 48 h even where administration is continued. The com seems to be stable under a variety of climatic condi

STREPTOMYCIN IN NON-TUBERCULOUS INFECTIONS

The serious toxic effects common in the meningeal or other forms of tuberculosis treated with courses of streptomycin need not deter the clinician using the drug for short periods in other infections. at this stage, when information concerning dosage indications is badly needed and supplies are relati short, it is in everyone's best interest that suitable c should be treated in hospitals which are fully equi with laboratory facilities, so that both diagnosis treatment can be bacteriologically controlled. another page Prof. Clifford Wilson summarises the findings of the Streptomycin Clinical Trials (tuberculous Conditions) Committee. The treatm many of the conditions mentioned is still in the e mental stage, and it seems advisable to confine the streptomycin to the treatment of meningitis and cæmia due to gram-negative bacilli and other pe resistant organisms which have been found to streptomycin-sensitive. We understand that a amount of streptomycin may be available for distri in the regions for the treatment of these conditio

POSTURE IN ANÆSTHESIA

Man's complex respiratory and circulatory m nisms are adapted to the erect posture. They de on a series of reflexes involving the voluntary mu often affecting muscle tone. In the operating-th the patient is placed in one or other of several unnat postures. Some of the effects of these postures unavoidable. Others, equally distressing, follow impr supervision of placement on the operating-table. anæsthetists have lately underlined the effects of unnatural postures. From observation on experim animals and on man Gordh[1] confirms that deep thesia abolishes most, if not all, of the compensa mechanisms involving vasomotor tone which are nor brought into play by change of posture. He empha the value, as a resuscitative measure, of a head-d tilt—to us the familiar Trendelenburg position. increased venous return in this position ensures filling of the right heart, which results, in accord with Starling's law, in slowing of the pulse-rate and in the blood-pressure. In animals the head-do position acts as an effective cardiac stimulant e after a few minutes of cardiac arrest.

Hasler[2] draws attention to the reduction in the v capacity so common in the anæsthetised patient. T is remedied by a moderate head-down tilt; but w the tilt is excessive the effects are far from good. T extreme Trendelenburg position, so beloved of t

ologist, draws the abdominal contents away from elvis but deposits them on the diaphragm, so ation may be seriously hampered. With a tilt of ıe vital capacity is reduced by some 15% and basal pulmonary atelectasis seems to be the rule. ead-down tilt is not alone in producing this evil ; the gall-bladder bridge, the lithotomy position, ven the lateral kidney position all reduce the vital ty by similar amounts. None of these can be rated as causes of postoperative "chests."

ong the more preventable ill effects are those due lposition of the patient.[3] Here the harm is done essure on certain structures, notably vessels and ı. Even the junior student knows that the arm ıg over the edge of the table is likely to cause a ırday-night palsy." Less familiar are the brachial- palsy due to malplaced shoulder-rests, pulmonary ism due to pressure on the calves, and damage to yes due to trauma during operations on the head ıce. These complications are avoidable by constant nce on the part of all in the operating-theatre. s have long been taught that an anæsthetised ıt gives no warning that his water-bottle is too in the same way students should learn that a ıt who makes no response to the deliberate trauma e operation also does not respond to any other ıa.

HOSPITAL BUILDING

CH of the hospital accommodation in Great Britain solete or obsolescent, and the need for extensive ıl expenditure was one of the most obvious lessons e surveys undertaken by the Ministry of Health g the war. It was therefore one of the underlying rs which tilted the scales in favour of nationalisation e hospitals. The principles now being laid down by Minister for the guidance of regional boards and rnors of teaching hospitals in their building projects herefore important. In general, the Minister is willing ave projects costing less than £10,000 to their etion, but he retains, of course, the responsibility ettling priorities as between the various schemes ıitted, since the total cost of labour and materials not exceed the total allocated to the Ministry for ital purposes and the whole cost will have to be e on the Ministry's estimates. In present circum-ces, moreover, all schemes costing more than £100 first be authorised by the Minister under regu-ns which apply to any kind of building in this ıtry.

ıe allocation of priorities thus vested in the Minister be no enviable task. There are a great many small mes of adaptation and improvements which must go ard. Clearly such objects as nurses' accommodation improvement of catering facilities must receive ı priority. Even if no new wave of hospital struction can take place for some time, the central artment in Whitehall will need to become thoroughly ert on many subjects affecting hospital accommoda-. In the United States the Public Health Service in the last few years built up an extensive section he approval of plans submitted under the Hill Burton and is sponsoring expenditure running to some million dollars a year. Their relations with the pitals are most cordial and it is much to be hoped our own Ministry will send its officials out far and e into the hospital world, so as to obviate the danger lecisions being taken solely on rules and regulations. he past, the necessity to raise the funds for proposed rations has been some safeguard against unessential emes—not always a very satisfactory test, since it excluded many much-needed improvements in the poorer localities. The new system with Government money behind it will work better than the old only if flexibility and continuous personal contact are assured. It would be no bad thing if every officer in Whitehall concerned with hospital administration spent a month each year in travelling round the hospitals with no particular agenda, to learn at first hand how the current rules and regulations tend to hamper the individual hospital.

STUDENT NURSES' SALARIES

THE arguments in favour of raising the training allowance of student nurses were strong when stated in these columns by a correspondent eighteen months ago,[1] and they have since grown stronger.[2] When so much depends on finding and keeping enough new entrants to nursing, it is important to be able to assure the possible recruit that during training she will need no financial support from home—support which many parents of suitable girls are not in a position to provide. Much has of course already been done to improve the lot of the student nurse, and in outlining its many advantages Dr. MacWilliam [3] rightly points out that there is a limit to what an impoverished country can offer for the services of a novice of 18. Nevertheless we are glad to learn that the Nurses and Midwives Whitley Council, meeting on Sept. 13, has in effect agreed to our correspondent's recommendation of a cash allowance of £100 a year. Under the new arrangements students entering training after Jan. 1 will receive £200 a year, out of which those resident in hospital will have to pay £100 for board and lodging—as well as income-tax and National Insurance and superannuation contributions. Existing first-year students, and those recruited before the end of the year, will, if resident, receive £100 a year, and free residential emoluments. Those who live out will receive free meals on duty, uniform, and laundry, besides their training allowances, and in future there will be dependants' allowances of 10*s*. a week for an adult and 5*s*. for the first child. Slightly higher training allowances will be paid to second-year and third-year students, who carry more responsibility, and to students in the special fields of tuberculosis nursing and midwifery. The basic £200 for the first-year student in general training may be compared with the present salary of £145 (for a woman) of which £70 is paid in cash and £75 represents the value of residential emoluments. (Before July 5 the three figures were £130, £55, and £75.) In future the training allowances will be the same for men and women.

The remuneration of student mental nurses and of student nursery nurses is still under consideration.

LEGITIMACY AND ARTIFICIAL INSEMINATION

ITEMS of news about artificial insemination always attract keen popular interest. The *News of the World*, in its issue of Sept. 5, published a report from its New York correspondent concerning the legitimacy of what we are learning to call a "test-tube baby." A wife, it is said, asserted that her husband "on her wedding night in New York informed her that he was unable to become a father and suggested that she consent to artificial insemination." She did so and a child was born. Apparently husband and wife afterwards parted company, for there were legal proceedings in a New York State court over the custody of the child. The judge awarded "principal custody" to the mother but allowed her husband the right of occasionally visiting the child. The wife asked for a declaration that the child was illegitimate, presumably in order to exclude the husband's right of making visits. The New York judge refused. Such a decision, he observed, would be "inhuman, inhumane, and contrary to the highest

concepts of sociology." He declared the child to be legitimate and the husband to be the legal father. Apparently he laid stress on the fact that the artificial insemination took place with the husband's knowledge and consent. The wife then moved into another State's jurisdiction and obtained from a court in Oklahoma City a ruling that she was entitled to the complete custody of the child.

Into the consequences of a conflict of laws as between different State jurisdictions in the U.S.A. we need not enter. The Oklahoma decision was perhaps a question of custody rather than of legitimacy. The action of a wife in seeking to bastardise her own child is unusual and not such as courts would normally encourage; the material evidence would be of a nature which in some jurisdictions is excluded. Be that as it may, the vital distinction, not clearly drawn in the necessarily abbreviated report to which we have referred, is whether the donor of semen is the husband or someone else. The two eminent legal authorities who contributed to the report of the Archbishop of Canterbury's Commission on Artificial Human Insemination [1] held that, if the donor is not the husband, the child is illegitimate; the fact that the husband has consented to the operation does not affect the position.

THE HEALTH CENTRE

IN the spring of last year the British Medical Association set up a committee, with Dr. Talbot Rogers as chairman, "to investigate and report on existing forms of group practice, including partnerships and other forms of collaboration between general practitioners and to relate this and other experience to health centre development." As part of its task the committee arranged a field survey of present-day practice, and the first part of the B.M.A. council's interim report [2] on the subject is devoted to an analysis of this survey. The conditions under which the general practitioner works are described and an analysis is attempted of the advantages and disadvantages offered to patient and doctor by differing methods of practice. Singlehanded practice is contrasted with various forms of partnership, or group practice, and while agreeing that "there are many highly efficient and successful practitioners working singlehanded, and some who could not work satisfactorily in any other way . . . the council considers the advantages of partnership practice outweigh its disadvantages; it is difficult to conceive a type of general practice more suited to the needs of the present day than a partnership of doctors combining the fine traditions of the family doctor with a variety of interests and experience."

The council emphasises the need for retaining in any future general-practitioner service those features of past methods of practice which have been "largely responsible for the high standard of medical work in Great Britain." Among these it counts the personal doctor-patient relationship, the intellectual stimulus of working in contact with colleagues from a common place of work, the variability and flexibility of practice to suit different conditions, the voluntary nature of partnerships, and the freedom of doctors to organise their work as they think best.

Equal care is taken to detect present defects needing to be remedied in future practice. Chief among these is placed the divorce of preventive and therapeutic medicine, which has ensued with the development and multiplication of local-authority clinics. Throughout the report the necessity is urged for the re-association of these unwisely separated compartments of medical practice so that the practitioner and the public-health officer may coöperate, and sharing each others' tasks be better able to give a continuous and coördinated to the families under their care. Unnecessary i of doctors should be ended; better and more l saving professional premises should be available; ancillary, secretarial, nursing, and dispensing help be put to the greatest possible profitable use. H beds should be provided in which general p could continue to care for patients who need help but not necessarily specialist investigation treatment. Special emphasis is placed upon the for easy access by general practitioners to di facilities, particularly in the fields of radiology pathology. From these considerations the council inevitably to the conception of the health cen well-equipped building housing a group of doctors carry out in a coördinated way all the work at done by general practitioners and clinic medical The range of service to be provided in such a is suggested, and methods of staffing and adminis are discussed. The council has not given its final on all arguable points—some it has reserved for discussion. Perhaps the one upon which we shall urgently await the council's opinion in its final report is that of the need for the p health centres of specialist services (including p radiological and pathological facilities). Me enough agreement has been reached for the be able to suggest that in urban areas a health should be the headquarters of up to eight prac serving a population of about 25,000, and to the type and extent of the accommodation that be needed to provide services adequate to such a tion. This detail of accommodation should be just the architect needs as the foundation for his and it is to be expected and hoped that the p of the council's report will be a stimulus to the tion of a variety of plans suitable for hea construction.

But this alone would not satisfy the council, rightly stress the urgent need for actual exp in health centres. Regretting the conditions necessitated the issue of circular 3/48, which d local authorities from submitting immediate p for health centre provision, the report goes on to s "there are new towns and large housing estates constructed in which some kind of accommodat the health services will have to be built; in would seem an actual economy to build health in the most convenient sites, instead of separate p for the doctor's surgeries and the local services." The council in conclusion reports "is satisfied that the most satisfactory form of at present and in the immediate future is practice from a common surgery. It believes logical future development will be the pro specially designed health centres from which general practitioners and the present local services can be provided. . . . Early experiment is able and a central committee should be without delay to offer guidance during this ex period and to collect information of the results ach

This report last week had a favourable rec in the national press. It was described as a d of great value, and we may well concur, for the c has done a great constructive service, first by its field survey, and secondly by its clarification of problems involved and its suggestions for their solution. The report should become a landmark in story of health-centre development, and we hope th may prove of great assistance to the members of authorities, of executive councils, and of local me committees, in whose hands the future of health ce now lies, and upon whose enthusiasm their development will depend.

THE MORALS OF EMPLOYMENT*

T. A. Lloyd Davies
M.D. Lond., M.R.C.P.
F MEDICAL OFFICER, BOOTS PURE DRUG CO. LTD., NOTTINGHAM

AN'T do it, doctor. Every time I goes on the job ne stomach, doctor." This is the problem which ntly faces industrial medical officers. An appar- nealthy and normal person, working in healthy, r even the best possible working conditions, finds rk repulsive. Is such a patient to be forced to ake work under those conditions because the ajority of his fellow workers find those conditions ctory or even to their liking? Or is he, because kes complaints which, though genuine, cannot be ntiated by any subjective or objective test, to be l to change the conditions of his work? This is medical problem; it is a moral problem and one however hard we may try, we cannot avoid.

these times, which politicians and more reliable of mankind have foreseen will be known as the f the Common Man, it is paradoxical that the al relationships of the Common Man have been the masses. A workman is engaged by an employer so much work, under certain conditions, for so hours, for a certain amount of money. Perhaps, trade unions meet employers, these items are the natters which can be clearly defined, but the essence ontract of employment is not the quantity of work rate of payment but trust and mutual welfare.

pose my patient is a bus-conductor. He is engaged bus company to issue tickets to passengers for so hours a day, with so many hours stand-over and any hours turn-round time. He is provided with ens at terminals, and he is paid wages which have agreed between his employer and his union. A few onductors may be promoted to inspectors, but for vast majority there is no relation between their est in their work, their enthusiasm, the amount of they do, or their politeness to passengers, and their rds, whether these be in working conditions, hours rk, or wages. To me it would be dreadful to know I was committed for the rest of my life to earn wages h are predetermined, prejudged, and unalterable, her I did my best to further my employer's interest, hether I merely took care not to get the sack.

wards of work are many: first, wages; secondly, ower that wages bring; and thirdly, the opportunity malice, hatred, and all uncharitableness." But the true reward of work is that it provides satisfaction he body, mind, and soul. Alas, work has become nymous with employment, divorced from the zest pride of a good job well done. Individuality has me lost in agreements between unions and employers, hat the clock, with inexorable precision, signals when unceasing burden of employment shall subordinate thought, fancy, and action of my patient to those of neighbours. Let anyone who doubts this look at the lling disgorgement from the mills and factories, at end of the day, of hurrying discordant human beings the modern jargon, personnel). Lest one moment ld be their own, they anxiously run to amusements time-wasting sports where the gregarious instinct es an appreciation of the real purpose of living.

Economic necessity" is said to be the reason for ng married women to return to the mills and factories time when the hours of men are being shortened. self-deception ever more blatant? For "economic ssity" is only a term which enables our own laziness to be blamed on a vague impersonal theory. Women must work for mammon instead of for their children.

The break-up of homes and families will extract a high price from the future. Benevolent authority, efficient school-teachers, balanced school meals, national milk, and orange-juice are poor substitutes for the worst parents. Both at home and at work the art of living is sacrificed to the spurious efficiency of material comfort. The idea of religion is even more unfashionable than the word. Instead of feeding boys and girls on algebraic equations and free milk, schools would do better to teach the inadequacy of man.

In the past we have discussed how many accidents take place at work, whether there is a toxic risk, or whether there is risk of harm to the workman, but this is not enough. If we are to build a country worthy of mankind we must think of work in terms of a job, freely entered, freely done, giving physical well-being, mental exercise, and spiritual hope.

* * *

Such a revolution in the conduct of human affairs is not a vague expression of humanistic hopes but a practical aim capable of immediate realisation. Craftsmanship is neither possible for, nor within the abilities of, all, but pride of achievement is still within the reach of those who seek fulfilment in living. The attitude of mind to work is as important as the job; to make certain that work gives the opportunity of interest and joy is the function of management; to seize that opportunity is the chance of the individual. The revolution of human beings, or the demechanisation (from within and from without) of the human body and soul, would achieve more for human well-being and happiness than all the material advances of the Industrial Revolution.

We must no longer think of work in terms of whether it is harmful but whether it is beneficial to free men with unfettered minds. When next, as employers, doctors, and workmen, we interview my patient who finds his work distasteful, let us remember that perhaps, unlike his fellow men who have become conditioned to disharmony, he has kept alive the spark of divine grace, so that before he can attain fulfilment he must have satisfaction in his work. He, not they, more nearly approaches the normality intended for mankind.

PROPRIETARY MEDICINES UNDER THE NATIONAL HEALTH SERVICE ACT

E. W. Godding
CHAIRMAN, STANDARDS COMMITTEE, CHEMISTS FEDERATION

It is clearly essential that the best medicines should be freely obtainable in a comprehensive National Health Service. But under National Health Insurance economy in prescribing was fostered by the substitution of drugs and by other questionable methods which often discouraged the conscientious doctor, and were responsible, at least in part, for "the panel" being regarded by the public as a second-rate service.

Hitherto, many new remedies have been produced as the result of research carried out by private firms, and if the N.H.I. policy of discouraging the use of proprietary medicines is adopted in the National Health Service the stimulus for research work by the pharmaceutical industry will be destroyed. Further, if the industry is discouraged from a vigorous policy of development the way may eventually be opened for an influx of foreign proprietary medicines. Active discouragement of proprietary medicines may therefore have long-term adverse effects on our national economy.

PRESCRIPTION OF PROPRIETARY MEDICINES

To determine how far the N.H.I. machinery discouraged conscientious prescribing, some retail pharmacists were invited to carry out surveys of about equal numbers of N.H.I. and private prescriptions covering the same districts and the same period. The results, showing the ratios of proprietary medicines appearing in each group of prescriptions were as follows:

---

*ed on a paper read at Roffey Park Rehabilitation Centre training course in April, 1948.

	N.H.I.	*Private*
LONDON S.W. AREA (MAY, 1947)		
No. of prescriptions	1422 ..	825
Proprietary medicines prescribed	82 (*5·8* %) ..	165 (*20* %)
LEICESTER CITY AREA (MAY, 1947)		
No. of prescriptions	755 ..	1000
Proprietary medicines prescribed	70 (*9·3* %) ..	398 (*39·8* %)
GLASGOW CITY AREAS (JUNE, 1947)		
No. of prescriptions	653 ..	1003
Proprietary medicines prescribed	23 (*3·5* %) ..	347 (*34·7* %)

To obtain further information on this question, with the coöperation of certain pharmaceutical houses, 118 doctors were sent an explanatory statement and an invitation to sign the following letter:

> Dear Sirs,—In reply to your letter I would confirm that, in my opinion, the machinery for the control of excessive prescribing, under the present National Health Insurance Act, also operates to discourage and dissuade the practitioner from prescribing many proprietary medicines which he considers useful for the treatment of his private patients.

Of the 118 doctors approached, 64 signed this letter; one signatory was the chairman of a panel committee. Since no steps were taken to ensure that the doctors concerned were a representative sample of the medical population, and since the reasons for not signing the letters (many doctors were on holiday) are not known, no statistical significance can be attached to the results. From the readiness with which the letters were signed, however, there is little doubt that a very large number of signatures could have been obtained.

Taken together the results of these two inquiries suggest that, where doctors are free to prescribe what they consider best for their patients, a much higher proportion of proprietary medicines is used, and it seems reasonable to infer that practitioners have not felt free to follow their judgment in prescribing for their N.H.I. patients.

On the other hand, though documentary evidence is not easily obtained, verbal reports of excessive prescribing under N.H.I. have often been received from pharmacists. As an example, when a N.H.I. patient left a district his landlady approached a pharmacist to dispose of 37 bottles of liniment, all unopened, prescribed for him by a local doctor. It does not require many such instances to show that the elimination of wasteful prescribing would pay for many useful proprietary medicines.

The following principle is offered as a basis for the prescribing of proprietary medicines in the National Health Service:

> *Any proprietary medicine showing a significant therapeutic advantage over existing B.P. preparations can be prescribed under its proprietary designation.*

The interpretation of "significant therapeutic advantage" obviously requires expert opinion. It should be noted that the term applies not only to new compounds but also to improved methods of presentation, providing these have a therapeutic significance. For example, though two preparations contain the same active ingredient, in one the drug may be presented in such a way as to act more quickly than in the other. Again, the potency of a drug may be maintained through the use of stabilising agents; and where particularly nauseating drugs are concerned special flavourings may also offer therapeutic advantages.

The practitioner should be given the duty of applying the criterion "significant therapeutic advantage," thus placing the initial responsibility where it rightly belongs. Any alternative system of central or local control must undermine the basis of professional practice. At same time, routine checks of unnecessary should be made locally and centrally along the force under the N.H.I.

It is suggested that scientific, medical, and ceutical representatives, with scientific members of pharmaceutical industry, should serve on a advisory technical committee whose main function be to provide the Minister of Health, when with an expert interpretation of the criterion "si therapeutic advantage." Reference to such a would be preferable to the too rigid control which be imposed by adhering to an approved list of pro medicines, and it should avoid the anomalies would almost certainly appear if local committees to act independently. A further advantage would the avoidance of the delay which would inevitably in admitting new products to an approved list proprietary medicines.

The function of local medical committees as the prescribing of proprietary medicines would recommend, as was the duty of the local panel what surcharges, if any, should be made in cases to them by the central authority.

COMMENTS

The effect of the suggested system, so far as pharmaceutical industry is concerned, would ensure financial rewards for research and deve work until the resulting new preparations were into the *B.P.* Doubt has, however, been to whether such uncertain rewards would continued application of the industry's resources development and presentation of the new the substances. More definite incentives might there considered. It is true that patent rights occasion, considerable financial rewards, but this cannot be universally applied. Some manufacturers' trade names might be considered, in this connexion it is worth noting that in many and Government departments scant respect is at paid to the registered names of manufacturers' prop preparations.

It is only fair to add that a recent Ministry of leaflet [1] states that "there will be no restriction drugs which may be ordered for free supply proper treatment of any patient so long as they medically necessary." Further, the Minister of said in the House on June 24 that patients are under the new health service, without restriction, every kind of drug and appliance necessary for treatment. He added that any doctor who fai prescribe these drugs would be breaking his term service.

The provisions [2] under the new Act for the surc of any doctor who is judged guilty of excessive scribing, which are very similar to those which ap under N.H.I., have not yet been used for the enforce of restrictions.

The prescribing of proprietary medicines in National Health Service will clearly require official consideration, but given a sense of resp by all concerned it should not be difficult to satisfactory answer to this question. As in all Go ment organisations, it is essential to avoid the s of creative ability and enterprise and to preserve a level of conscientious service.

CONCLUSION

The Ministry of Health has a new responsibil towards the pharmaceutical industry. Until now substantial part of the population outside the scope nal Health Insurance has made it possible for the try to follow a vigorous programme of research development, but this position may be sharply sed if the policy under N.H.I. is continued and ded in the new service.

accept the benefits of the industry's research while ing it the material encouragement for continuation have a disastrous effect on its future ; on the other , the stimulation of further research and development he industry would contribute much to a vital and ressive health service.

have received invaluable help from Mr. L. Boon of tosan Ltd., and Mr. W. W. Knott of Parke Davis & Co. in obtaining the data quoted in this article.

ERNATIONAL ORTHOPÆDIC CONGRESS IN QUEBEC

COMBINED meeting of the American, British, and dian Orthopædic Associations was held in Quebec June 3 to 6, under the joint chairmanship of the dents of the three associations : Dr. R. I. HARRIS oronto (A.O.A.), Mr. S. ALAN S. MALKIN (B.O.A.), Dr. EDOUARD SAMSON (C.O.A.)

SLIPPING OF THE UPPER FEMORAL EPIPHYSIS

r. S. KLEINBERG (U.S.A.) maintained that incipient ing of the upper femoral epiphysis called for elimina- of the epiphyseal plate by drilling and the postpone- t of weight-bearing till there was clear evidence of hyseal fusion.

r. BECKETT HOWORTH (U.S.A.) reviewed 254 cases, hich 224 had been treated surgically. Operations included attempted manipulative reduction (37), reduction (35), transcervical osteotomy (7), subtro- teric osteotomy (10), and insertion of a bone peg e front of the head (134). In 131 of the last group, ing occurred without further trouble. The condition ld be treated at the earliest stage, when pegging the procedure of choice ; drilling without pegging ineffective. He advocated early movement. Closed tion was only possible if slipping had been recent.

r. CLARENCE H. HEYMAN (U.S.A.) had followed 42 s for 2 years and found a good result in 30. Manipu- n had given a good radiological and excellent clinical lt in 17, and a good radiological result in a further The results in the 8 cases of surgical osteotomy were with aseptic necrosis in 7. Cheilotomy of the osuperior part of the femoral head in 3 cases gave h-improved function without degenerative changes. 3 patients submitted to 10 operations for surgical on of the epiphysis clinical and radiological results good.

r. PHILIP WILSON (U.S.A.) dismissed the possibility n endocrine cause, preferring to think it mechanical, as the treatment. Early diagnosis, with nail fixation. important. He believed that cases thought to have e well with manipulation would have done equally without it.

DEVELOPMENTAL COXA VARA

r. A. B. LEMESURIER (Canada) reviewed develop- tal coxa vara, which, he said, usually first became ent with a limp or waddle at the age of 3–4 years. ilial cases occurred. The most characteristic feature a gap in the bony femoral neck, which usually filled tually. Intertrochanteric osteotomy had been per- ed in 12 cases, and in all but 1 the gap had been edily closed. A case seen before important coxa vara developed might be treated by a central bone-graft.

r. WILLIAM T. GREEN (U.S.A.) regarded the condition failure of ossification of a part of the femoral anlage. rder to secure sufficient abduction, intertrochanteric otomy was preceded by adductor myotomy.

r. ALBERT KEY (U.S.A.) considered that disappear- e of the gap, which did not always happen spon- eously, might be accelerated by drilling. In adult s he had chiselled away the great trochanter without ch further weakening of the abductors. A Whitman's onstruction had been followed by osteo-arthritis of new joint 15 years later.

ARTHROPLASTY OF THE HIP

Dr. ALEXANDER GIBSON (Canada) reviewed 104 cases of vitallium-cup arthroplasty of the hip with the Kocher posterior approach. The results were : good, 55 ; satisfactory, 21 : poor, 14 ; unclassified, 14.

Dr. PAUL C. COLONNA (U.S.A.) thought that it would be difficult to deal adequately with contracted soft tissues, particularly the ligament of Bigelow, through a posterior approach, and that weight-bearing at 4 weeks, as practised by Dr. Gibson, was unusually early.

Dr. M. N. SMITH-PETERSEN (U.S.A.) had always aimed at producing congruous surfaces, and it was to secure adequate exposure of the acetabulum that his approach had been developed.

CONGENITAL DISLOCATION OF THE HIP

Dr. JUAN A. FARILL (Mexico) spoke of operation on cases of irreducible congenital dislocation of the hip without gross deformity of the femoral head or acetabulum. A wide exposure of the hip was supplemented by subtrochanteric femoral shortening and by the formation of an extra-articular shelf if the acetabulum was shallow. Reduction had been secured in all of 12 cases and had been maintained in 11. No necrosis of the femoral head had been observed.

ARTHRODESIS OF THE ANKLE

Dr. W. E. GALLIE (Canada) described arthrodesis of the ankle-joint by a method which he had used in 25 cases without failure. Near each margin of the joint an anteroposterior mortice was cut, half in tibia and half in talus, each channel being about $1\frac{1}{4}$–$1\frac{1}{2}$ in. high and about $\frac{1}{2}$ in. broad. A tibial graft was then driven into each of the mortices. The articular cartilage was not removed.

COMPRESSION ARTHRODESIS OF KNEE

Mr. JOHN CHARNLEY had followed Dr. Albert Key in arthrodesis of the knee by pin fixation of each fragment and bracing the pins together in such a way that they could be forcibly approximated so as to impact the cut bony surfaces with a force of the order of 50 pounds. In 17 consecutive cases of osteo-arthritis (degenerative arthritis) or healed tuberculous arthritis, the junction had been solid by the 21st, 14th, and even 12th day after operation.

ARTHROPLASTY OF THE KNEE

Dr. HAROLD B. BOYD (U.S.A.) for Dr. J. S. SPEED and Dr. PHILIP C. TROUT had followed up 64 cases of fascial arthroplasty of the knee for 5–25 years or longer. It took 5 years to achieve full improvement, and thereafter function remained surprisingly constant. Only cases following acute infective arthritis or trauma were selected. The operative technique was that of Campbell. The results were as follows : good, 28 ; fair, 17 ; poor, 8 ; failures, 11. The poor results were due to inadequate movement (4), instability (1), both inadequate movement and instability (2), pain in addition (1). The authors concluded that : (*a*) careful selection was imperative ; (*b*) granted this, 70% of patients should have good or fair results, and another 12% would prefer their final state to that of ankylosis : (*c*) major functional adaptations might occupy 5 years ; (*d*) if instability appeared, it usually did so during this period : (*e*) thereafter the condition was usually maintained over many years : (*f*) recent advances, notably the development of penicillin, had greatly diminished the number of suitable cases requiring arthroplasty.

Dr. J. EDOUARD SAMSON (Canada) reviewed the results of 50 operations for arthroplasty of the knee in 43 patients, all over 20 years of age. He adopted a simple technique embodying sufficiently wide resection ; the preservation of an intercondylar tongue of tibia, the lateral ligaments, and the patella ; and the interposition of a free flap of fascia lata. 'Cellophane' had been used in 2 or 3 cases, but had caused a reaction and needed removal. Except in a few of the earlier cases, no physiotherapy was given, beyond active exercises, but nearly all received 1–4 conservative manipulations. The functional results were always better than the radiological, and were classified as follows : excellent (painless, stable, with flexion to 90°) 15 ; good (similar, but with flexion to 40–60°) 14 ; fair (similar, but with flexion to 20–40°) 9 ; bad 15, including re-ankylosis 12 (with infection 4), instability 1, and pain 2. Dr. Samson concluded that (*a*) arthroplasty of the knee had a place in major surgery, (*b*) it carried no inordinate risk, (*c*) gonorrhœa had, till now, provided the most frequent and most favourable cases, (*d*) cases of rheumatoid polyarthritis should not be operated upon unless arrested; (*e*) cases due to osteomyelitis or tuberculosis were unsuitable; (*f*) good musculature was imperative, and (*g*) the patient's coöperation was indispensable.

DENERVATION OF THE ELBOW-JOINT

Dr. **James E. Bateman** (Canada) had performed neurectomy for the relief of pain in the elbow-joint on 150 cases. The operation was carried out through three incisions—at the medial border of biceps tendon, at the lateral border of biceps tendon, and posteriorly for the nerve to anconeus. Of 8 patients followed up after neurectomy for pain from osteo-arthritis or traumatic arthritis, all had less pain and showed a slight increase in the range of movement.

SUBTROCHANTERIC LIMB SHORTENING

Dr. **Lawson Thornton** (U.S.A.) described a method making use of the nail-plate designed for the treatment of intratrochanteric fractures. The nail was driven into the neck of the femur, and then the appropriate length of femoral shaft was excised immediately below the great trochanter; a spur was left attached to the inner part of the upper fragment, to control rotation. The fragments were brought together and fixed by means of screws and the nail-plate.

MENISCI OF THE KNEE

Mr. **I. S. Smillie** reported that 1300 menisci removed in 7 years included 28 which he considered discoid. He classified them as "primitive" (15), approximating to complete discs; "intermediate" (7), less clearly discoid; and "infantile" (6), being broad menisci with a very thin central zone and somewhat resembling the meniscus of the full-time fœtus. Of the menisci, 8 showed cystic degeneration—a change found in 22% of 468 lateral menisci excised. The other lesions found in the discoid menisci varied with the anatomical type. Only 4 of the primitive discs caused snapping; the others were found in the course of meniscectomy for other symptoms. Besides producing a depression in the upper surface of the meniscus, the femoral condyle exerted a grinding force upon the meniscus and so produced horizontal cleavage. The consequent rift tended to open secondarily on to the lower surface and later the upper, but the horizontal character of the main defect could still be demonstrated. Lesions of the "intermediate" type did not differ from those found in the more typical lateral meniscus; the thin portion interposed between the femoral and tibial condyles was never injured. The "infantile" type often showed an incomplete transverse tear.

Mr. **T. J. Fairbank**, in a study of the knee-joint changes after meniscectomy, had compared the pre-operative and postoperative radiographs in 107 cases of meniscectomy, excluding all cases revealing pre-existing osteo-arthritis. Three groups of changes were found: a distally directed ridge at the margin of the femoral articular surface; flattening of the femoral condyle; and narrowing of the joint space. When this followed lateral meniscectomy, there was often some widening of the medial compartment. A study of elasticity curves of articular cartilage showed that a sustained load produced depression. Morning or evening radiographs of the weight-bearing knee showed its "space" to diminish by 1 mm. during the day. This joint compression must cause a transfer of load to the menisci in a centrifugal manner.

PERONEAL SPASTIC FLAT-FOOT

Dr. **Robert I. Harris** (Canada) and Dr. **T. Beath** (U.S.A.) recalled that the deformity and stiffness in peroneal spastic flat-foot had long been ascribed to reflex muscle spasm from stimuli arising in the tarsal joints because of severe weak flat-foot. Electromyography revealed no spasm of the peronei; they were merely shortened, and deformity often persisted under anæsthesia. Sloman in 1921, and Badgley in 1927, had demonstrated calcaneonavicular coalition in some cases, and now a further anatomical anomaly had been found—namely, a talocalcaneal bridge comprising a p the medial part of the talus meeting the posterior of the sustentaculum. This anomaly, which co revealed by posterosuperior radiography of the cal was found in 12 out of 17 cases of peroneal 3 of the remainder showed calcaneonavicular coali and the other 2 complicated rheumatoid arthritis. bridge might be a synostosis or a coalescentia calcanea, and, if the latter, either a syndesmosis synchondrosis. It had been observed by Pfitzner, related it to the os sustentaculi. The authors cons that the cases with developmental bony anomalies sh no spasm, and that those with arthritis of the joints showed real spasm. In their opinion the follo three types could be distinguished: rigid flat-foot to talocalcaneal bridge; rigid flat-foot due to cal navicular bridge; and arthritic flat-foot with spasm.

Mr. **S. A. S. Malkin** thought that a fourth should be added: the adolescent spasmodic flat- following strain of the subtalar and midtarsal joints.

ASEPTIC NECROSIS OF BONE AFTER INJURY

Dr. **Edward L. Compere** (U.S.A.) spoke of the necrosis which may involve large intermediary fr in fractures of the long bones. Regeneration rese that of a bone-graft, and serial radiographs show temporarily increased density. Union normally occ but was delayed.

Dr. **Dallas B. Phemister** (U.S.A.), in dealing the management of the aseptic necrotic head of femur, recalled that in the adult such necrosis im death of the overlying articular cartilage. At a 6–18 months, when it reached the part of the opposite the upper acetabular margin, the fragile gro edge of tissue was apt to yield, so that the upper of the head broke off and collapsed under the of weight-bearing. With fracture of the femoral this happened only if the fracture united. To p this collapse, Dr. Phemister treated 4 cases of un fracture of the femoral neck showing aseptic n of the head by threaded wires and the inserti a tibial graft or grafts through the neck into the part of the head. In each case the fracture and extensive transformation of the femoral head place without collapse, but the time was still too for full assessment. With non-union of 3 years or a reconstruction operation or an arthrodesis was p able. Tibial grafting had similarly been carried out, seeming success, in a case of united femoral neck early collapse of the necrotic head.

Mr. **H. Jackson Burrows** made a plea for preven Once cortical bone had been deprived of its blood-su delay in union was inevitable; worse still, once cancellous end of a bone in an adult had died its art cartilage was destroyed, and little or nothing could done. Apart from proper handling of an injured l it was imperative to avoid unnecessary open operat or, conversely, closed manipulations when open ope would be less damaging.

CERVICAL FRACTURE

Dr. **William A. Rogers** (U.S.A.) observed that tr ment of cervical fracture or fracture-dislocation sh aim at protection of the spinal cord and nerve-r and fixation of the fracture. An emergency collar used till skull traction could be applied. If the verte canal remained seemingly narrow, operation was formed—in the later cases under local anæsthesia. 4 cases the vertebra above the lesion was lifted by gripping its spinous process. Fixation with no stainless-steel wire was supplemented with bone ch and the position was checked radiographically. Trac was continued for 3–5 weeks, and then walking usually begun with a cervical brace. Of 32 patients underwent operation, bony fusion occurring in 20 an average of 4 months. Those not operated up received 10–12 weeks' traction followed by 6–8 mont cervical support. All patients walked finally with support, and 26 resumed full work.

Mr. **E. A. Nicoll** indicated that function depend not upon a good anatomical result but upon stabil Factors favouring instability were intervertebral- damage, rupture of the posterior spinal ligaments ution of the vertebral body. Instability might operation. Simple compression-fracture of a al body was stable, and its treatment was conre. *Fracture-subluxation* with *ruptured inter*al disc and interspinous ligament was reduced ension by gravity and could be treated conely, but it was important to avoid hyperextenFracture-dislocation with locked facets demanded eration and grafting.

FRACTURE-DISLOCATION OF THE PELVIS

F. W. HOLDSWORTH had treated his 50 cases of e-dislocation of the pelvis, due to direct violence. he manner of Astley Cooper, with a partially ng towel held tight with weights and pulleys and trapping traction on the lower limbs, or pin n if one side were dislocated. Reduction was complete. The cases were followed over an e of 5 years. Of 27 with dislocation of a sacro-iliac 2 returned to heavy work, but 15 continued to ain, which was referable to the joint: of 15 t sacro-iliac dislocation, 13 returned to work. ly 2 complained of persistent pain. This tended rove with time, but its persistence for 2 years demand consideration of sacro-iliac arthrodesis.

FRACTURES OF FEMUR

E. HARLAN WILSON (U.S.A.) had come to regard al fixation with screws, and if necessary vitallium as the treatment of choice for fractures of the of the femur. After operation early movements carried out, with sling suspension for 3–5 weeks. z, or use of crutches by the younger patients, was d when the patient could extend the knee fully, to a right-angle, and raise the limb against gravity. mal range of movement was restored within six hs.

LUMBAR DISC DEGENERATION

f. STEN FRIBERG (Sweden) had been able to confirm logically that the lumbar vertebral body above a red intervertebral disc, especially the 4th, slid rds on flexion and backwards on extension. In ts examined soon after death degenerative changes found to be most pronounced in the anterior parts e discs, except the 4th and 5th where they were ly in the posterior parts.

SCOLIOSIS COMPLICATED BY PARAPLEGIA

K. G. MCKENZIE and Dr. F. P. DEWAR (Canada) found that scoliosis with paraplegia was usually enital, sometimes idiopathic, and less often due to myelitis, rickets, or neurofibromatosis. The defor- was severe; and myelograms might show a block e apex of the deformity. Failing an early response nservative treatment, operation should not be unduly yed. The dura was found to be tightly stretched at site of an angular deformity, compressing the spinal which was not itself stretched. It was released by ion of the dura.

PRESIDENTIAL ADDRESS

Harris recalled that the American Orthopædic ciation was but eight years old at the time of tgen's great discovery. In 1912 Macewen had pubd his work on the growth of bone. Then had come wars, and great advances with them. During all time the general surgeon was gradually becoming visceral specialist. There was a common meetingund for all branches of surgery in the basic sciences, arch, and teaching. The claim of orthopædics to ecial field of surgery carried responsibilities. Advance possible over a much broader front than that of e technical improvements. For instance, in histology re was the newer knowledge of intercellular subnces; in biochemistry there was much to learn about ogenesis, and endocrinology had something to tribute to this; the physiology of muscle-fibres ded further study; while in anatomy the relationship ween structure and function could be investigated by dern methods.

RADIOACTIVE ISOTOPES FOR CLINICAL RESEARCH

MEDICAL RESEARCH COUNCIL STATEMENT

THE Medical Research Council have made arrangements to obtain from the United States Atomic Energy Commission limited quantities of certain radioactive isotopes for medical research, including therapeutic investigations. Further, it is expected that regular supplies will soon become available from Canadian and later from British sources.

The Council now invite institutions to submit for consideration detailed programmes of research in the clinical field. The application should include adequate information on the following matters:

(*a*) Specification of the radioactive isotope required.

(*b*) Quantity desired. (Radioactive isotopes with half-lives of less than 30 days may be allocated in fulfilment of one request, in amounts sufficient for six months' needs, with arrangements for shipments at intervals of not less than a week.)

(*c*) Date and rate of deliveries desired.

(*d*) Name of institution at which the materials will be used.

(*e*) Names and research experience of investigators who will use the materials. This list should include the names of the radiotherapist and physicist who will collaborate in the research.

(*f*) Purposes for which the materials will be used, with methods of administration and the dosage proposed.

(*g*) Protection and safety measures to be employed to safeguard the health of the workers. (Useful guidance will be found in the *Introductory Manual on the Control of Health Hazards from Radioactive Materials*, which may be obtained from the Council on application.)

(*h*) Proposed financial arrangements, including the sources from which the applicant will defray the cost of the materials.

Information under these headings, except (*h*), is required by the United States Atomic Energy Commission, as a condition for their supply of the isotopes. The Commission supply isotopes only for accepted lines of research the results of which are fully published, and which are conducted in institutions open to visits from investigators in this field of all nationalities. The Medical Research Council should be notified of any such visits by workers from other countries to any institution receiving the isotopes through their agency.

Progress reports must be made to the Council every six months. In the case of therapeutic investigations, the institution supplied with radioactive isotopes must undertake to register the patients treated, according to the cards and system of the Statistical Department of the General Register Office.

In its application to the Council for radioactive isotopes the institution is required to give the following undertakings:

1. That the materials supplied will not be used in any manner other than that disclosed in the application.
2. That the institution will maintain all necessary protection and safety measures to avoid the special hazards to health arising out of the possession, handling, and use of radioactive isotopes, and will allow inspection of all such protection and safety measures by representatives of the Medical Research Council.

The supplies of radioactive isotopes are at present limited and the materials are costly, especially on account of charges for transport.

It is expected that the isotopes in greatest demand will be radiophosphorus, P^{32}, and the radio-iodine, I^{131}. The following information about the preparations of these two isotopes available is given by the Commission:

Phosphorus 32

Half-life 14·3 days. Beta radiation 1·71 MeV. Supplied as phosphate ion, probably in the form of Na_2HPO_4, in a solution containing 0·5–3·0 millicuries per millilitre. Chemical analysis is furnished with each shipment. *Material will meet the following specifications:*

Concentration.. ..	Greater than 0·5 mC./ml.
pH	7–9
Total solids	Less than 10 mg./ml.
Non-volatile matter ..	Less than 5 mg./ml.
P (inert)	Approximately 0·025 mg./mC. added. (Carrier-free material is available if desired.)
Cl	Less than 5 mg./ml.
Fe Ni Al	*Content so low that no precipitate is formed at pH 7–9*

Iodine 131

Half-life 8·0 days. Beta radiation 0·6 MeV. Gamma radiation 0·367, 0·080, and probably also 0·65 MeV. (10–15%). Carrier-free, in neutral or weakly basic solution containing 0·3–2·0 millicuries per millilitre. Chemical analysis is furnished with each shipment. *Material will meet the following specifications:*

Concentration.. ..	*Greater than 0·3 mC./ml.*
pH	7–9
Total solids	Less than 1 mg./ml.
Te inactive	0·1 mg./ml.
Te active	Less than 1×10^{-4} mC./ml.

The Council will not accept responsibility for the accuracy of the statement as to radioactive content which will accompany each sample, or for the freedom of the sample from toxicity.

The cost of the materials will depend on various factors, including the demand, but is unlikely in the first instance to be less than £1 per millicurie for I^{131} or 10*s.* per millicurie for P^{32}.

While every effort must be made to utilise these therapeutic developments and possibilities to the full, there can be little doubt that, from the long-term point of view, the treatment of cancer and allied diseases is most likely to be advanced by the encouragement of tracer investigations, using both radioactive and non-radioactive isotopes. *Materials for this purpose are also obtainable from the Council, and at present, in view of the small quantities involved, no charge is being made.*

The need for extreme caution in the clinical use of radioactive isotopic tracers cannot be over-emphasised. The safety of non-radioactive tracers should recommend their use in clinical investigations.

DANGERS AND LIMITATIONS OF RADIOACTIVE ISOTOPE THERAPY

Certain dangers inherent in radioactive isotope therapy are becoming recognised, especially in the case of radiophosphorus administered internally as inorganic phosphate. The most serious of these are possible injury to the reproductive organs, genetic damage, the induction of leukæmias and the hastening of the appearance of leukæmic conditions, and the production of malignant tumours. The leukæmogenesis and carcinogenesis, including induction of sarcoma of bone, are likely to be delayed effects, *with a long latent period of possibly five years and probably often longer.* Accordingly, in the present state of knowledge, it is usually unwise to employ radiophosphorus in the treatment of patients of either sex in the reproductive period of life or in patients where the expectation of life exceeds five years.

In general, it must be concluded that therapeutic trials of radioactive isotopes should be limited to cancer and allied diseases, and polycythæmia vera. With rare exceptions, radioactive isotope therapy should not be used in non-malignant conditions. Further, the opinion has been expressed that, in the present state of knowledge, radioactive isotopes should in no case be used in the treatment of children suffering from non- diseases.

Despite these limitations, there is an important for investigation in the therapeutic applications of active isotopes. At first, it will be necessary to techniques and to confirm and extend the results of American workers, while profiting from their c Subsequently, it seems likely that the devel selectively concentrated organic compounds radioactive isotopes may be a promising line of in tion. Probably there will be an immediate though limited field for the use of external applicators sources of beta rays. Experience with artificial ray sources, such as radiocobalt (cobalt 60), in therapy is at present very restricted but this is a for experimental development when adequate supplies become available.

All correspondence should be addressed to the Advisory Panel on the Allocation of Radioactive I Clinical Research, Medical Research Council, 38, Old Street, London, S.W.1.

Public Health

HYGIENE IN PALESTINE

ERIC HARDY
F.Z.S.

UNDER the British mandate, Palestine's public health improved considerably from what had been during the Turkish occupation. control of the mosquito-breeding places greatly the amount of malaria-infested land, and the d of the packs of pariah dogs which had haunted the *of the cities at sundown since Biblical times* remo dangerous source of rabies. In more recent Jewish settlements, with their technical advisers University of Jerusalem and elsewhere, developed of Lake Huleh, Jebel Usdum, and the plain of which had previously been undeveloped swamps. All this useful work is threatened by turbance of the civil war and the lack of scientific *vision of many of the native parts of the* count

The malaria position at the end of the roughly that the malaria risk was high in the Valley from the Syrian border to the south of the Sea, chiefly on the Transjordan side. It was also in marshy parts of the coastal plain near the Sukreir, the Wadi Rubin, and the Tantura area, Wadi Faria near Nablus, and south of Faluja. Jericho, Tiberias, and Safad it was high from Se to December but otherwise moderate; but there little risk around Jerusalem, Hebron, and Lydda.

In 1940, Krikorian and Bedrechi listed 9 sp their *Atlas of the Anopheles Mosquitoes of* published by the department of public health in salem, and a strict and wide control of m the villages was supervised in the later years of mandate by Dr. J. MacQueen, the director of services, and Dr. W. K. Bigger, the A.D.M.S., with Jewish and Arab personnel, and also assistance officers of the R.A.M.C. Together with Jewish sci a malaria research hut was maintained in the no Huleh region where the intensity of malaria in the *villages was very high, the splenic index being* 80– with an extremely high death-rate among children 10 years, so that the natural increase of the pop there was negligible. Lieut.-Colonel R. St. John L. R.A.M.C., describes[1] *an experiment in the mass* of the Huleh villages, made with Dr. Bigger's in January, 1946, primarily to control malaria and borne dysentery, another widespread insect-borne of Palestine which is likely to increase, since the nati practises little personal sanitation.

The three commonest rural malaria-carrying mos in Palestine are the palæarctic *Anopheles sergent superpictus*, and *A. saccharovi* (*elutus*), the last-na

ırgest anopheline in the country. breeding in swamps
stagnant water like Huleh. Many adult mosquitoes
found resting in the dark interiors of cattle byres
papyrus living-huts in the villages. The water is too
for them to breed at Huleh (in the north) at that
of year, but the mosquitoes emerge to lay their
in the warmer weather of April. The malaria season
from then to December, when the mosquitoes
ne torpid again and are then more easily accessible
raying.

ing to the war-time development of the Palestine
h Company's plant at the Dead Sea outbreaks of
ia were traced to the fresh-water swamps on the
-western shores of the Dead Sea at Ein Fashka.
these were controlled by cutting down the vast
ets of phragmites and arundo reeds and admitting
to the cleared channels of fast water from this well-
n spring. Towards the end of the mandate D.D.T.
largely replaced the Paris Green hitherto used in
ing waters.

October, 1942, a malaria survey of the Wadi el
ah—the Arabah of the Bible. an arid desert over
iles long between the Dead Sea and the Red Sea—
nade by Major Lumsden, during the active breeding
n of the mosquitoes. He found both in the Ghor and
adi Arabah *A. superpictus*, the Ethiopian *A. d'thali*,
rgenti, and *A. multicolor*. In February, 1946, an
lition of the Jerusalem Naturalists' Club to the
el Arabah remained a fortnight there. when the
uitoes were studied by Major F. Jacousiel, R.A.M.C.
s found [2] that even in this warm subtropical area
uito breeding is at a very low ebb in February. A
canty specimens of *A. sergenti* and *A. multicolor*
found, adult specimens of the first-named sheltering
ave near the spring of Ein Arus in the Ghor. Larvæ
th species were collected in swamps in that neigh-
ood, which is close to the south shore of the Dead
and at Ein Weba, a small oasis in the heart of the
ah desert. Of the culicine mosquitoes, the expedition
l the large larvæ of *Theobaldia longiareolata* in
t water at almost every spring and marsh visited in
Ghor and the Arabah, and a few larvæ of *Culex*
ns were collected in the springs near Ein Beida.
latter species, with *C. laticinctus*, are the common
n culicine mosquitoes of Palestine, tolerating the
dirty water of ancient stone cisterns, Roman caves,
ete tanks and native wells, and they are abundant
ative village houses. *Uranotænia unguiculata*,
iorhynchus buxtoni, *Ochlerotatus caspius*, and *O.*
us breed in the marshy parts of the country, and
ariæ in saline water in holes by the sea. *Culex*
guus and *C. tritæniorhynchus* prefer cleaner water,
are common.

her insect-pests, like small sand-flies (*Phlebotomus*)
house-flies (*Musca*), are probably as numerous as
naturally can be, and are less likely than the
uitoes to be affected by the lack of scientific
rvision.

Two Outbreaks of Typhoid Fever

Clydeside

sharp outbreak has occurred in the Greenock,
Glasgow, and Gourock areas of Clydeside. By
5 the diagnosed cases totalled 29. The first 3 cases
in holiday-makers in Gourock who had crossed the
h of Clyde to Kilcreggan, a favourite place for
c parties, and there had drunk water (unboiled)
a stream. The next batch of cases came from
bers of a Church organisation, about 700 of whom
on an excursion to the same resort. Large numbers
nown to have drank unboiled water from the stream
24 cases have so far been notified. The remaining
ses are Greenock youths who were camping at
reggan. All cases are due to *Salmonella typhi*. So
he organism has not been discovered in the stream;
e samples taken have revealed 24 types of bowel
nism but no typhoid organisms. It is known that
nage from a few dwellings reaches the stream above
point from which the water was taken, and samples of fæces have been sent for examination from 20 residents of these dwellings. The one food factor common to all cases is the consumption of water from this stream and it is almost certain that this is the source of the outbreak. A vigorous press campaign locally has been prosecuted to ensure that all possible cases are brought to light. It is anticipated that a few more cases will be detected, but the main outbreak seems to have passed.

In Shropshire

On Sept. 5 a night-sister at the Robert Jones and Agnes Hunt Orthopædic Hospital, Oswestry, complained of severe headache and was feverish; she had felt unwell the previous day. On Sept. 6 another night-sister and the assistant matron reported with the same symptoms. Next day there were 5 more cases, in a third night-sister, 2 day-sisters, and 2 maids. On the 8th and 9th positive Widal reactions were reported in 9 further members of the nursing and domestic staff, and in 2 children in separate wards who had been feverish since Sept. 5 and 6. Six nurses who went on leave on Sept. 3 and 4 have been reported as cases. Up to the night of Sept. 11 there were 24 cases among the nursing and domestic staff and 4 patients, and a further 3 cases have been confirmed among the outside domestic staff who had been sent home ill.

The signs and symptoms in all cases have been severe headache, temperature generally from 103 to 105°F at night and 100–101°F in the morning, injected conjunctivæ in most cases, and constipation. There have been no preliminary gastro-intestinal symptoms. The original diagnosis was influenza, but on Sept. 7, owing to the continued fever, Dr. Aylmer Lewis took a sample of blood for Widal reaction from a patient who had not had T.A.B. inoculations at any time and on the 9th this was reported as showing a titre of 1/125 for *S. paratyphi-A* and of 1/25 for *S. typhi*. Later samples showed a titre of 1/1000 for *S. typhi*; cultures of blood and fæces have so far been negative. The milk-supply has been investigated, samples of blood and urine and rectal swabs having been taken from all milk handlers at the farms supplying the hospital and from all the kitchen staff; samples of water are also being examined, and so far the distribution of cases and other factors suggest that the water-supply is the most likely source of infection. The population at risk in the hospital is about 400 patients, 170 nurses, 50 indoor domestic staff, 80 outdoor domestic staff, and 12 medical and clerical staff.

Paratyphoid at a Girls' Camp

A party of 42 members of the Oldbury (Worcestershire) branch of the Girls Life Brigade were camping in a small church hall in Pevensey Bay, Sussex, from Aug. 16 to 30, and since returning home many of them have developed paratyphoid fever. By Sept. 10 there were 19 suspected or confirmed cases in hospital. The church hall had main water and drainage, but with 6 adults and 36 girls in it the conditions must have been rather cramped and the lavatory accommodation and cooking facilities were in close proximity. Information was obtained from the local food office as to the main sources from which this party obtained their foodstuffs, and these were investigated, but nothing suspicious has been revealed.

One of the party, who had been doing the cooking, was taken ill with diarrhœa and vomiting about Aug. 22 and had to be suspended from cooking duties. She was removed to hospital for investigation, but by Sept. 11 it had not been proved that this was a case of paratyphoid fever. However, a small boy, aged 8, who had also been in the camp ill with diarrhœa, vomiting, and pyrexia on Aug. 22 was proved to have a paratyphoid B infection. It is understood that this boy had been isolated in the church hall, but under the existing conditions the isolation could not have been fully effective.

It seems probable, therefore, that this boy was the source of infection in the other cases. As to the origin of his infection it is unlikely that he contracted it in Pevensey Bay, since there have been no other cases there, and it seems probable that he was infected before his arrival on Aug. 16.

No secondary cases have arisen in Pevensey Bay up to Sept. 13.

In England Now

A Running Commentary by Peripatetic Correspondents

THIS new impulse towards brightening our homes and persons is disquieting to sober conservatives like me. I suppose the urge started with women; after seeing the New Look (which gives them an old one) I can believe almost anything of the other sex. Not that men are altogether guiltless. There's that little matter of the patterned American ties, already mentioned in these columns.

I've always thought that men's clothes should be so quiet that nobody notices them. With these ties that's impossible: they yell at you. I own that I sometimes regret that I haven't a personality that could stand up to such a tie; I confess, too, that I have sourly envied the owners of these ties their American dollars or their American friends. But despite this emotional tinge I stand four-square by my principles—or did until the other night.

I was invited to a private party in honour of a much-loved American orthopædist. After our meal he made a little presentation to five British colleagues as a memento of their visit to him last year. The box was undone; and there, in vivid argument, were the five loudest ties in creation. The ties were donned. Do you know, they were actually very smart; and I felt dim and shabby. Anyone wanting a nice Paisley pattern in exchange for a quarrelsome multihued tie should get in touch with me. Only one thing worries me: surgeons, with their robust extroversion, can wear them all right; but can the physician with his more subtle and refined nature? We shall see. Meanwhile, I attract all eyes with the yellow waistcoat I bought next morning.

* * *

I was interested in what the Empire Conference on Scientific Information Services had to say about abstract journals; as was to be expected they emphasised the need for prompt publication and comprehensive coverage of the scientific journals. They even suggested that abstracts might be prepared from proofs of papers without awaiting their actual publication in the journals; if this arrangement could be applied to journals which publish preliminary reports, then abstracts would be as eagerly awaited as the 9 o'clock news. Better still, the research-worker could ring up abstracts every week or two and report verbally on his latest discovery. Promptness of publication of abstracts seems to be a soluble problem, but complete coverage is a more troublesome matter. It is not always easy to get a copy of the *Proceedings* (in Persian) *of the Society of Industrial Medical Officers of Abadan*, or of the *Compt. rend.* (in Polish) *of the Academy of Sciences of Pinsk.* But even when all the known medical and scientific journals are covered important gaps will still be left.

My wife is a careful reader of the *Daily Rapide*, and we often have the following sort of conversation. She looks up from the paper and asks, "Do you know that extract of dried bear's skin cures rheumatism?" I blush and admit ignorance. "Well, here it is: Prof. Stefan Ivanovitch of Irkutsk has cured hundreds of cases in this way and has increased Soviet productivity by 18%." Or it's Dr. Myron C. Jeggerts of Alabama who has cured peptic ulcers by making the patient stand on his head for 5 minutes daily. After these blows to my professional pride I look out for the further report in the usual journals and abstracts and of course find nothing there. I know the excuses the editors will offer: "How do I know the reports are true?" Surely we all know that our press is the finest and most reliable in the world; and when a newspaper has to print in four pages all the world's news, pictures, and advertisements it need not bother to publish lies. "Then why did not Professor Ivanovitch publish in the usual journals?" Why should he? He is a man of genius; he is not looking for academic promotion and does not need to have a minimum number and weight of reprints. He told the *Daily Rapide*'s correspondent and so reached the whole world and not merely a small coterie of unimportant biased and jealous "scientists."

Sir Isaac Newton discovered the differential calculus and never bothered to publish it at all; many orthodox scientists have sealed up the report of their
in an envelope which was not to be opened for 20
knowing the world was not yet ready to receive
message. Suppose a press correspondent had
Newton, seen a MS. on his table full of hierogl
inquired about it and been told "Oh, that is my
ential calculus"; or if the correspondent was
with the scientist and he happened to drop a hint
the contents of his sealed envelope. Surely it
the bounden duty of the press in such
make known to the world the treasures that
might have remained hidden. I am sorry that the
Society Conference did not arrange with the N
Proprietors Association to keep abstracts informed
scientific discoveries that receive their first
in the lay press.

But even when the press is fully covered there
remains the "occasional" publication which must
not be neglected. A striking example has just
my notice. From time to time I order a cask of
the Much Binding Cider Co. I read the
literature with interest as it is pleasant to know
qualities of what you are going to drink. The
I got an exciting special leaflet. One of the
the company had visited France and had come
a cider of most remarkable qualities; it was of
type, of very high alcohol content, and would
indefinitely; and then in large capital letters I
informed that it was a very potent *aphrodisiac* and
be drunk in the strictest moderation. This was
discovery that the world—if not the scientific
has been waiting for, and if I had not
leaflet the world might never have known. Now
have the laugh of all my pharmacological friends.
they go on frittering away their time on bits of
uterus or intestine or the hundredth anti-hist
local anæsthetic I will be doing some critical
on this most beneficial and potent (that word
not be misunderstood) of therapeutic agents. It
that I am not the actual discoverer; but it is
discoverer but the man who makes the world
a discovery who receives the gratitude and p
mankind.

One of the curious and inexplicable o
our surgical life is the tendency of diagnoses
consecutively. Perhaps for months we will not
fracture of the femur, and then—presto!—one
in of the shaft, a few hours later another of the n
perhaps the next day a compound one. Not an ep
I may presume, for they come from wholly
parts of the country; but whether the moon was
or whether the accident incidence was filled up
to overflow at that particular moment I am never
to make up my mind.

Or perhaps we will not see a patient who
cæsarean for a considerable period. But then, if we
one, there are sure to be more close on its heels.
it is the same with other diagnoses. Lately the
has been the organ affected. We have seen
litis, fatal and non-fatal, severe and mild, and
noma of the sigmoid in old and young (the last
age 35) and in male and female. They have re
simple excision, end-to-end anastomosis,
perineal resection, and all the variations of the
techniques mentioned in the books. When
over, we may expect to see no more for months in
modest-size hospital.

I had never seen anything like it before, but for
a memory from long-past classical studies gave me
answer. "That is a vomitorium," I said firmly (ch
with one of the local boys, by the way, proved this
right). I had to explain its purposes. My friend
at it with awe. "I always heard the Germans
thorough," he said, "but I had to see this to
just how thorough they are."

Letters to the Editor

THE AGRICULTURAL WORKER

r.—By their article on Aug. 21 Dr. Keatinge and Littlewood have performed a service which has been required. It is time that attention was focused he social conditions of the workers who provide th much of our daily food. I find it difficult, however, lieve that bigger farming units and a special medical e will provide the answer to the man-power prob-

The authors say that the farm worker has little ect of rising in the world. They mention the e of the Government agricultural training scheme x-Servicemen, but not the fact that the Scottish rtment of Agriculture has a waiting-list of over 0 for smallholdings, while Holland, Lincs, has over ex-Service applicants.[1] The personal factor in rship and responsibility therefrom is of considerable rtance. Surely the provision of more smallholdings mall farms would attract greater numbers to the and offer the chance of rising in the world to those the necessary ability. The authors' aggregation rms into bigger units would presumably displace piers of smaller farms and might well displace people from the land, as did the enclosures of the eenth century.

th the statement that small farms are uneconomic not qualified to disagree, but I would be chary of ting the economist's yardstick for a way of life h is the vocation of the small farmer, and in connexion a biological process which is so far removed from the anistic processes of industry. It appears to me that any of the advantages of aggregation of units given he authors, such as easier marketing and bulk ng, can be obtained equally well by coöperative ods, as among the smallholders in the Vale of ham.[2]

e writers state that the change from horse to tractor he farm has made 200–300 acres of arable land the mum for the efficient utilisation of implements and "the present trend of scientific and mechanical ation, too, will increasingly favour larger units of uction." Would it perhaps not be wise to adapt machine to the man and develop the tractor or other implement according to the land and farm on which ll be used? The coöperative ownership by a group rmers of the larger, more expensive, and less used s of machinery is a rather different matter from aggregation of farm units, and is one which could y be encouraged by the Government today. I find fficult to see how such aggregation of farms would ilitate the provision of scientific and technical ce." Is that not a question of availability of experts, s it implied that "compulsion" would be more y enforced with such aggregation? Education and ople are methods more acceptable to the British erament.

many of the advantages claimed by the writers d be obtained by less revolutionary methods through medium of education and existing village organisa- s. The Government are already tackling the housing blem, and much more could be done in this direction. ision of water, sanitation, and power are other urgent irements. Assurance of a just reward would probably more than any other single measure to repopulate countryside.

he authors propose a special medical service. Could the existing country doctor carry out all the necessary minations on entrants into agriculture and other ervision required, backed if necessary by a regional sultant service of specialists in agricultural medicine, lternatively by a regional specialist with an interest he agricultural aspects of medicine? Let us hope it is not necessary to turn the whole structure of our ntryside upside down in order to congregate our cate farm workers into a large conglomeration of and machines under the ever-watchful eye of industrial doctor, perhaps also an industrial chologist, and without doubt a foreman mechanic.

Let us remember that the "efficient," "economic," "large-scale," inorganic, monocultural system of agriculture, developed in the U.S.A. during the last and present centuries, has created one of the largest man-made deserts in the world. Perhaps the "dust bowl" of America cannot happen in this country, but let us not be complacent in our "can't-happen-here" attitude. Let us think much and experiment a lot before we throw overboard the traditional methods of agriculture which have maintained the soil of this island in an unequalled state of fertility and productivity over hundreds of years. Before we grub up our hedges, cut down our hedgerow timber, and grub out our yeoman farming stock let us be quite certain that we know what we are doing.

That is not to say that there is no place in English farming for large units. There have long been larger and smaller units, but the standardisation and industrialisation of agriculture is a conception fraught with danger. I should like to recall Sir George Stapledon's words in *The Land: Today and Tomorrow*: ". . . there is a grave risk of the family farmer being slowly and steadily swallowed up by large and fully equipped farming companies, and this to my mind would be the greatest ill that could befall the countryside."

Hitchin, Hertfordshire. ROBERT WIGGLESWORTH.

SALARIES IN GOVERNMENT SERVICE

SIR,—May I supplement the letter in your issue of Sept. 4? Since temporary M.O.s in the Ministry of Pensions do exactly the same work as the established officers, they are surely entitled to the same remuneration. No allowance is made to them, however, for the absence of pension rights, so they are underpaid vis-à-vis established officers to the extent of £150–200 per annum. Furthermore, should a temporary officer qualify for extra-duty allowance, he is given a bonus of 3% on his salary while his established colleague gets 8%.

Other injustices which should be ended are the recruitment and promotion of established officers while there still exist temporary officers with years of satisfactory service in the Ministry. Such officers should be taken on to the establishment and their pension rights back-dated. Moreover, this sensible method of recruitment would enable the Government to dispense with the services of some of the Civil Service Commission.

Now that the new Act is in operation, surely all Government medical services should be reorganised. At the moment many Ministry of Pensions officers are doing work which rightly is the Ministry of Health's, and on a salary scale below that of Ministry of Health officers.

TEMPORARY M.O. (PENSIONS).

STUDENT SELECTION

SIR,—As the number of methods of selection increases there is a growing tendency to forget certain fundamentals. Nobody overlooks the dilemma produced by an excess of candidates, but fewer and fewer people seem to realise that to deny an individual entry into a field of human endeavour which he is eager to join strikes at the very roots of human dignity. Since all short-time methods of selection are admittedly fallacious in a significant proportion of cases, I submit that equitable selection can be achieved only by raising the standards of training and by suffering a considerable degree of wastage.

If the supply of potential medical students far outstrips the demand is not this a splendid opportunity for obtaining an even better type of doctor by stepping up the intellectual and practical achievements demanded in the medical courses? Admittedly, at least in the beginning, this would involve a great wastage of those who fall by the wayside. But is it not foolish to think that a high level can be achieved without such wastage? A Minister who tried to ordain that all musical composition except that of masterpieces must stop would be regarded as insane. Yet this is exactly what we are doing in trying to cut out wastage of medical students. In a complex activity such as the practice of medicine nothing but an actual attempt can reveal the master and the inept.

[2] bid, p. 134.

Biology has shown us the only foolproof method of selection—that of trial and error and of survival of the fittest. This must remain the method of selecting future doctors if the standard of the profession is to go up and not down. Present difficulties may prevent us from giving full rein to this natural method, but at least we should not be blind to the viciousness of present-day restrictions. By making a virtue of necessity we are in danger of perpetuating an undesirable state of affairs. Any society which desires to have a sufficient number of people possessing the highest skills must be prepared to suffer wastage in training.

University of Edinburgh.

EXSANGUINO-TRANSFUSION IN ACUTE LEUKÆMIA

SIR,—In his preliminary communication of Sept. 4 Dr. Piney says, "it is impossible to obtain very large quantities of blood at any one time in England." I do not understand on what grounds he makes this statement since he apparently did not apply to any of the regional transfusion centres. Had he done so, and if his patient belonged to one of the commoner blood-groups, his request could probably have been met without difficulty.

Experience so far acquired of exsanguination-transfusion in acute leukæmia suggests that this treatment has probably only a temporary effect. The decision to use it will, therefore, always be a difficult one, but should it ever become a recognised form of treatment it would be well to realise that the provision of the needed amounts of directly matched homologous-group blood will present great difficulty in certain cases. For example, group B and especially group AB, Rh-negative blood will be most difficult to provide in the quantities used in Dr. Piney's case, and group A and group O Rh-negative blood will not be much easier. Group O Rh-negative blood is always in great demand because part of the available supply (only about 7 out of every hundred donors belong to this group) is given to patients whose ABO and Rh groups have not for one reason or another been determined. Many of these patients are, in fact, Rh-positive, and some of them, though Rh-negative, belong to group A. If only the ABO group of these patients were determined, group A Rh-negative blood could be used instead of group O Rh-negative blood, thus lessening the constant drain on the latter. Considerable quantities of Rh-negative blood are, of course, used for the exsanguination-transfusion of infants with hæmolytic disease of the newborn.

It is improbable that any blood-bank could supply on demand sufficient Rh-negative blood for the type of transfusion described by Dr. Piney. In other words, such exsanguination-transfusions should always be deliberately planned in consultation with the regional blood-transfusion officer.

Ministry of Health, London, S.W.1. W. D'A. MAYCOCK.

SHORTAGE OF BLOOD FOR TRANSFUSION

SIR,—Since the war ended, the blood-banks have become progressively less well stocked with blood, presumably because, the fervour of patriotism having died down, donors are far fewer. I understand that the Ministry of Health makes itself responsible for rationing blood to hospitals and doctors, while the Medical Research Council looks after the needs of the research-worker. But practically no attempt is made to increase the number of donors, and so add to the stocks in the blood-banks. Of course, I must admit that some postal-cancellation stamps do inform us that blood donors are urgently needed, but it is doubtful whether many (or any) donors are obtained in this way.

My attention was forcibly called to the matter by Bessis and Bernard's[1] advocacy of exsanguino-transfusion in the treatment of acute leukæmia—a procedure which in the adult requires many pints of blood. The effects are so dramatic (although admittedly cure does not result[2]) that, having seen some of the cases in Paris during the meeting of the European Hæmatological Society, I wished to try it here; but there was not enough blood. One moribund patient was Paris, and was given two exsanguino-transfusions, the expected result—a remission.

Why, then, have the French so much blood, so little? The answer is to be found in the Gallic that is prepared to make use of the strength and nesses of men and women. Thus, every donor is "chits" which entitle him to purchase extra Now, as many members of the public imagine t weakening to give a pint of blood, they feel hap being given the chance of making good the loss those who realise how totally harmless is the are, nevertheless, delighted to get something m eat. Then again, playing on the vainglory of eve each donor is given a card, signed by hand, thank for generously parting with his blood. And, on the of the card, there is an appeal to the emotions: have given of your blood as a gesture of our co humanity, and it may save the life of a woman in of a child (perhaps your own), of an injured wor and so forth.

There are many other useful hints to be gained study of the methods of the Centre National de fusion Sanguine, so admirably organised and Tzanck. For instance, the donors put their arm t a hole in a wooden partition, and so see neit needle nor the blood; and everybody knows how less it hurts if you do not see it. Propaganda, es by posters, has worked wonders in France; why it not do so here? The story is told of a man who to go to the head of a queue in Paris because, he "I have a blood donor's card." "Get to the tail," everybody, "so have we."

CAUSE OF PRIMARY HEPATIC CARCINO

SIR,—The high incidence of primary hepatic c among Bantus[1] has not yet been explained. Ke has shown that it is not due solely to racial factors, the incidence in American negroes is not unduly Berman[3] has pointed out that in races having a incidence of hepatic cirrhosis there is a high in of primary liver carcinoma and vice versa . communities primary hepatic carcinoma predom affects males,[4] and this is especially true of Africa.[1] Where the incidence is high the disease on an average at least 20 years younger than i where the incidence is low. Berman also noted the hepatic cirrhosis on which the cancer superv not multiple nodular hyperplasia due to acute n but, as Stewart[6] had pointed out earlier, a more progressive fibrosis, and that the cirrhosis ant the cancer.

Of the suggested ætiological factors a number c eliminated as not worthy of credence as direct ca e.g., malaria, syphilis, alcohol, heredity, and tra Many parasites have been blamed from time to ti few merit serious consideration. The trouble with of them is that they are either too ubiquitous ubiquitous enough. Thus hepatic distomiasis explain the high incidence in China but hardly in U and schistosomiasis is a scourge both where the inci is high and where it is low. The same can be of other parasites—coccidia, echinococcus, la *Cysticercus fasciolaris*—though the last-named experimentally produced liver sarcoma.[7]

Chemical factors have aroused considerable in since the discovery of the carcinogenic action of the matic azo compounds, *o*-aminoazotoluene and dim aminoazobenzene, and some other pure chem Yet there are difficulties about applying these e mental results directly to liver carcinoma in Thus these carcinogens will cause malignant tu in other organs besides the liver—e.g., vesical papi

3. Berman, C. *S. Afr. J. med. Sci.* 1941, 6, 145.
4. Willis, R. A. Pathology of Tumours. London, 194
5. Berman, C. *S. Afr. J. med. Sci.* 1941, 6, 11.
6. Stewart, M. J. *Lancet*, 1931, ii, 565.
7. Bullock, F. D., Curtis, M. R. *J. Cancer Res.* 1925, 9, 42

ugh the liver is always directly damaged.[8] The pro- tive changes after azo compounds are regenerative here may or may not be a complicating or simul- us cirrhosis. Indeed it is unlikely that an irreversible sis could be induced by dimethylaminoazobenzene, se of the rapid development of hepatomas. These vations do not concord with the observed cirrhosis- oma relationships in man.

ere is direct evidence that carcinogenic substances ccur in the human liver, but their nature importance are uncertain. The investigations of enberg et al.,[9] des Ligneris,[10] Hieger,[11] and Steiner [12] e summed up as follows :

Source of liver extracts	*Carcinogenic content*
cerous Bantu liver	Considerable amount
n-cancerous Bantu liver ..	Moderate amount
n-cancerous non-Bantu liver ..	Little or none
n-cancerous American negro iver	Little or none

e evidence suggests that these carcinogens are ls and are not related to the aromatic azo compounds. origin is uncertain, but it is suspected that they n some way connected with the diet. In my view is a precise link between malnutrition and primary carcinoma in Africans, and a specific group of ical carcinogens may be involved.

tention has been drawn [13] to the frequency and rtance of malnutrition in Uganda, where nearly African child passes through a clinically recognis- phase of malnutrition, which may recur in adult In this condition there is fat infiltration in the liver,[14] h may progress to a cirrhotic condition, thus explain- n part the very high necropsy incidence of cirrhosis e liver in East Africans.[15] Some other features of an pathology appear to be due indirectly to this mal- tional disease. In Uganda gynæcomastia is rela- y common, and there is a high proportion of noma of the male breast in East Africans.[16] With this ecomastia and tendency to carcinoma in the male a feminisation of the whole body; it is often cult to sex the bones of Uganda Africans, and testes are small and atrophic. There thus may connexion in Africans between liver derangements feminisation of the male. In hæmochromatosis, inisation, loss of hair, and impotence, with the s often atrophic, are far commoner than is generally sed and in frequency come next to the classical d of symptoms.[17]

he mechanism of this connexion appears to have elucidated by Glass et al.[18] who showed that the otic liver could not inactivate œstrogens. Nor is osis necessary, for Hibbs [19] and Klatskin et al.[20] described gynæcomastia in malnutrition. This come about in two ways: the liver may be unable to tivate œstrogens either because of vitamin-B iency [21] or because of a lack of lipotropic factors.[22] nutrition in East Africa is known to be associated pathological changes characteristic of lipotropic- r deficiency.[14, 23] Thus from an early age the liver alnourished Africans cannot metabolise œstrogens. ch are retained in the body and produce feminisation. œstrogens can induce malignant changes—sarcomata he sites of injection, interstitial cell tumours of the es, and carcinoma of the breast in both male and female mice [24]—and they can also cause hepatomas in male mice.[25]

It therefore seems reasonable to postulate that œstrogens might be the cause of the high incidence of hepatic carcinoma in Africans and in any other community where malnutrition and other causes lead to liver damage in young males. The effects would be less notable where liver damage occurs late in life. The accumulation of œstrogens in the African liver and their absence or comparative absence in the undamaged livers of American negroes and of white races would explain the known occurrence of carcinogens in some livers and not in others. On this hypothesis it is unnecessary to invoke other causes, such as parasites and such chemicals as the aromatic azo compounds which the primitive African would be unlikely to meet.

This hypothesis could easily be subjected to experimental proof, though I am not in a position to do this. The administration of œstrogens to male mice with dietetic liver damage or fibrosis should lead to a high incidence of liver carcinomata. If it is correct, the association between cirrhosis and carcinoma depends on the fact that it is only cirrhosis which will cause liver damage over a long enough period to allow carcinoma to develop.

This hypothesis arises out of work done at Mulago Hospital, Kampala, in conjunction with Dr. H. C. Trowell and Dr. E. G. Holmes. They are not responsible for the opinion expressed.

Bristol. J. N. P. DAVIES.

M.R.C.P. EXAMINATION

SIR,—The membership is a test of ready general medical judgment. Since a consultant is one who is suddenly called to give a firm opinion on an unfamiliar case which has baffled those who are familiar with it, this is surely the right kind of test. There may be a place for another examination which demands a high standard in one department of medicine, but that is an inferior principle. "The era of the general physician is passing," according to your correspondents on Sept. 4. Have they never been at a loss to assign a case to its proper specialty? In the all-specialist era, who will be able to do this?

There is no logic or fairness in insisting on a three-year delay after qualification. In all examinations held on this imperfect earth, the undeserving will sometimes fluke his way through; how will it help us if he does so after some years of "experience"? The really good man, the one who is going to benefit most from his experience, will sometimes pass, fairly, just after qualification; why keep him down artificially?

The system of an important examination (like the title and the volume numbering of a periodical) ought to be preserved unless change is really imperative. Continuity is precious. If your two correspondents of Sept. 4 had their way, there would soon be two things, the Old Membership and the New Membership. Some would be sure the Old was better, and others that the New was better. Disputes and confusion would be inevitable.

If the results of the membership depend more on chance than they ought, the reason is not the system but the excessive number of candidates, which has certainly introduced a most undesirable atmosphere of pressure and haste. I suggest the following remedies:

1. The examination should still be held every three months, but no individual should be allowed to take it oftener than once in six months.

2. Really bad candidates should be referred for more than six months, the period varying with their ignorance.

3. If these measures did not suffice, the entrance fee could be increased and a substantial sum refunded for passing at the first or second attempt.

These measures would deter sportsmen from putting a bit on the membership as if it were a horse. To disavow personal bias, let me add that I mean to specialise, and that it was neither very soon after qualification nor at the first attempt that I became

LETTER TO A NEPHEW

SIR,—The charming letter from an uncle to his nephew, published in your Students' Number is so very much out of date that I hasten to send you a more practical version :

MY DEAR CHARLES,

You are more fortunate than I, for when I thought to enter the profession of medicine I had no near senior relative with whom to discuss this important decision. None the less, I am flattered that today any of the young should consult an ageing relative about the future.

Forty years ago, when I became a student, no one had the faintest provision of the degeneration that was about to overtake not only the profession but the whole social life of the nation, during his working life. With the coming of Lloyd George's Panel Act certain wise men did predict a falling off in the status of the doctor and the standards of practice ; but their forecast was an anæmic dream of what has actually happened. For with the passing of the Bevan Act, the whole of a great profession has been wrapped in complete subservience to the State, from which there is little likelihood of immediate escape. If they had become Civil Servants under the Act, there might have been some minor hope. But doctors have been made something far inferior to Civil Servants, and without their protective armour.

What you have to consider firstly therefore is this. The profession that you propose entering is undergoing a major upheaval. It is changing, via interference from the State, its whole system of practice, and the relations between doctor and patient are bound to alter accordingly. How exactly they will alter is not known ; but the portents are bad. From your point of view you must, as a primary question, ask yourself whether you are prepared to take on your life work in what we will euphemistically call a "service." When the body of the profession were free men they gave service freely to their fellow men, following their own ideas of what was just and right. Yet there were always recognised services that could be entered by students after qualification, usually by further competitive examination. The Royal Navy, the Army, the Royal Air Force, the Colonial Service and its special branches like the West African ; but above all, the finest service of its kind that has ever existed—the Indian Medical Service. But these services never had any gross excess of candidates in their most flourishing periods. Indeed, the Colonial Medical Service always had some difficulty in attracting sufficient candidates. In other words, the practice of medicine in a "service" has never appealed to any but a very small minority of those qualifying as doctors, for the very good reasons that the restrictions of a "service" have always been incompatible with the freedom of thought and action essential to the most intimate of all the professions.

Bearing this in mind, that you are not entering a free profession as in the past, but a departmental service of the State, you may contemplate in the abstract the ethics of the life of a doctor. You will find this very admirably set forth in the letter on p. 358 of THE LANCET of Aug. 28. But the picture there presented dates from before July 5, 1948, and even before 1913 when the first steps were taken down the old rotten weedy slope of State control. You must remember that your patients are going to look upon you now not only as some sort of a "doctor" but mainly as a mechanism through which they can obtain money as sickness benefit, medicine, and many other material things. And you yourself, if a practitioner, are going to find that if you attend to all the regulations and fill in all the forms you will achieve an easier existence by the miserable technique of least resistance. You will hardly have time to enter into your patients' difficulties and gain their trust as in the old days. This is the curse of a "service" !

But do not misunderstand me. There are and always will be those among us who *must* be doctors because any other life is intolerable to them. Some of your background makes me think that you may be numbered amongst these happy few. They are not found in any special class or creed, though naturally more will be found to belong to medical families. At the present time there are large numbers of young men of wholly unsuitable type applying to be apprenticed to the profession, to gain a poor if reasonably certain livelihood, and under the delusion that it will give them some social status. If many of these are admitted, the status of the profession will become lower than it has ever been before, and its social position will be only in the annals of the past. The panel system of Lloyd George was mentally wrong, and has added less than nothing regard of the citizen for the profession. Now every a "panel doctor" there is every reason to think th position will be made immeasurably worse.

To help you to decide this vital question for yo and you alone can decide it—it will be useful to tell what I should do if I had a son in the same dilemma. boy were a fool, I should let him do medicine if he in the hope that he might acquire some sense and a though a poor one. But suppose he were a bright intelligent type, I would go to any lengths to stop him t himself away on the desultory treadmill of the State if I were ultimately convinced, because he defied me insisted on a medical career, that he was one of those *must* be a doctor—just as there are those who *must* priest or who *must* be a veterinary surgeon—I should p relent at the last.

So I can offer you no simple and easy way out of thorny problem. But I can point out that there is one star ahead in a miserable world. You may even live enough to see it, and if it comes to pass during your life you may even be glad if you should choose the prof of medicine. The bright star that I see ahead is this:

The curiously mixed race known as the English passion for freedom, for doing their job in their "own d tinker fashion." Whenever they have in their become oppressed by a vile doctrinaire, be he C Cromwell or James II, the English have thrown him off his works, and reverted to their free way of life. So they see the great light of freedom, and in some m they will rise up and throw off the present false claim State to direct their lives, and they will cast out their sors and their false gods, though they may starve an before they do it. Under such circumstances the pr of medicine will revert to its old system of a free life be carried on in the highly satisfactory manner tha obtained from Hippocrates to 1913. That light worth seeing.

Your affectionate uncle,

THOMAS NE

London, W.1.

IMPORTANCE OF FAT IN THE DIET

SIR,—The view has often been expressed tha vitality of the consumer is influenced by the le his daily fat intake. Thus, the high fat intake American people is considered by Cruickshank[1] one of the factors responsible for their display of dence. Conversely, the reduced fat intake of the people is now alleged to be the cause, or one of the of their present tiredness and proneness to fa Bicknell[2] has written of the present diet being " lessly deficient in fat," adding that "lack of fat is we are all worn out"; the same opinion has expressed by Leyton.[3] Lord Woolton[4] has spok his certainty that the diet is dangerously deficie fat, and Leitner[5] has discussed the diet's nutrit imbalance on that account. Others have written simi Since this belief has received considerable publicit might be profitable to examine how far it is sup by the evidence.

The average daily fat intake during the war years reported to be about 80–100 g.[6]: at present it is s to be about 60 g.[7] The first question is whether war-affected communities consuming a reasonably quate diet with a similar or lower fat intake disp the same symptoms. In the Channel Islands,[8] d the occupation, the daily fat intake was about 40 g., in Switzerland[9] during the war period it was 40–50 yet reports indicate that a high level of fitness preva particularly among the young. Next, it may be inq whether communities whose normal fat intake is are stigmatised by inferior vitality. The South Af

AND DEATH IN A CONCENTRATION CAMP

R,—I should like to comment on the report of Wolff-Eisner's book in your issue of Aug. 7. As a ner in the concentration camp at Auschwitz-enau and later in a camp in Friedland near Breslau, l opportunity to observe the consequences of famine.

disagree with the statement that raw potatoes ed diarrhœa. On the contrary, in our camp we erately and successfully combated diarrhœa with potatoes. The effect was similar to that of an e diet. Nocturia was not due to "irritable bladder" r. Wolff-Eisner thinks; nor could it have been the equence of incipient famine œdema, for nocturia polyuria started from the first day in prisoners ing from Slovakia in a good nutritional state. It simply the consequence of food being given in the of great quantities of soups—4–6 litres daily. lently such quantities of fluid could not be wholly eted in the day-time, and the evening soup especially to be excreted during the night as it would have e by every healthy subject. In the later stages, of se, the elimination of œdema fluid in the horizontal tion from the lower parts of the body contributed he nocturia in a smaller degree.

were vitamin deficiencies were not observed, because toes, which are rich in vitamin C, and various other tables containing carotene and vitamins B and C tituted in most camps the bulk of the food (kohlrabi, e and yellow turnips, and red beet). It is not surng, therefore, that in Dr. Wolff-Eisner's experience addition of yeast had no remarkable effect.

octors coming to our camp from Theresienstadt rved, as did Dr. Wolff-Eisner, that deficiency of was an important cause of famine œdema, for tion of bacon to the diet caused the œdema to disear. Perhaps a more plausible explanation is that addition of fat calories saved body and blood protein n destruction and enabled the very small amount rotein in the food to be utilised. In all cases of ine œdema in our camp I found the chief cause to ack of calories, although the protein intake (in the n of horse meat) during most of our imprisonment ost covered minimum requirements. But, as the rie intake was always insufficient, body protein t have been destroyed to make up the required d of calories. The result was a fall in blood proteins, ch in turn was the chief cause of famine œdema.

HOMOLOGOUS SERUM HEPATITIS

SIR,—In the summary of his paper of June 19 (p. 941), Dr. Borensztejn claims that homologous serum hepatitis is transmissible to rabbits. This statement was based on an experiment in which the single rabbit inoculated intravenously with blood from a fatal case of jaundice died two months after inoculation and was found to have necrosis of the liver. The single control rabbit inoculated with distilled water remained well. In case it be thought that the problem of homologous serum jaundice has now been solved, I think it should be mentioned that blood from cases of infective hepatitis and homologous serum hepatitis have been inoculated into rabbits on numerous occasions by various workers in recent years with negative results. As an illustration, three experiments were carried out in 1942 at the Wellcome Institute in London. In the first, two rabbits were inoculated intravenously with blood from a patient with infective hepatitis; in the second, two rabbits were injected intravenously with blood from two cases of jaundice in soldiers of the U.S. Army who had received icterogenic yellow-fever vaccine: and the third pair received blood from two patients with jaundice following inoculation of an icterogenic pool of convalescent mumps serum. All these animals remained perfectly well over a period of a year.

Virus Reference Laboratory,
Central Public Health Laboratory,
London, N.W.9.

F. O. MACCALLUM.

SIR,—In view of Dr. Borensztejn's claim to have transmitted homologous serum hepatitis to a rabbit, some essentially negative work carried out in 1945 may be worth putting on record. Starting from the hypothesis that homologous serum jaundice was not caused by a virus, but was the result of sensitisation by some product of liver damage present in the injected serum, attempts were made to produce a similar disease in rabbits. Two rabbits were treated with carbon tetrachloride over a period of some days so as to produce progressive liver damage; when this was at its height serum was obtained from the animals and was inoculated into other rabbits. Blood samples were taken from these rabbits at weekly intervals and determinations of serum bilirubin were carried out. In all 16 rabbits were observed over a period of up to four months. The results were at first encouraging in that 10 animals showed a progressive rise of serum bilirubin up to a maximum of 1·67% in one instance, while one animal died of acute liver atrophy. As the work progressed, however, it became evident that the effects noted could not be attributed to the experimental processes but were most likely due to some extraneous factor such as a dietary insufficiency or the presence of some infective agent in the stock of rabbits, and the work was therefore discontinued.

While shedding no light on the ætiology of homologous serum hepatitis these results show that liver disturbance, progressing occasionally to acute necrosis, may occur in rabbits apparently spontaneously, and that claims to have transmitted the human disease to rabbits cannot be seriously entertained unless supported by observations on a much larger series of test and control animals.

D. J. BAUER.

Wellcome Laboratories of Tropical Medicine, London, N.W.1.

MAN INTO WOLF

SIR,—With regard to the annotation under this heading on July 10, I think it is of interest to quote Cervantes,[1] who, freely translated, wrote:

> "To suppose that these northern people become she or he wolves is a very great mistake," said Mauricio, "although many believe they do."
>
> "How is it, then," said Arnaldo, "that everybody says, and it is taken for certain, that in the fields of England are herds of wolves which are human beings so transformed?"
>
> "Such a thing," answered Mauricio, "is impossible in England, for in that mild and very fertile country neither wolves nor any other kind of harmful animals such as serpents, vipers, toads, spiders, or scorpions can grow; it is well known that if any sort of harmful animal is brought to England, on arrival there it dies; and if from that

---

[1] Los Trabajos de Persiles y Segismunda, book 1, chap. 18.

country any earth is taken to another country and a viper is encircled with it, the viper cannot escape from this imprisoning ring until it dies."

Spain's greatest writer of all time spoke here, as always, in friendly and sympathetic terms of England.

Santa Cruz de Tenerife. JOSE DURAN MOLINA.

POSTCRICOID PHARYNGO-ŒSOPHAGEAL PERFORATION DUE TO ENDOSCOPY

SIR,—In his article of June 26 (p. 985) Mr. Goligher discussed œsophageal and pharyngeal perforation during gastroscopy and œsophagoscopy. Most often perforation is the direct result of this operation, and takes place at the site of the pathological condition for which endoscopy has been undertaken. Occasionally, however, it is produced in the postcricoid region, at a point remote from the primary lesion. As only a few of these accidents have been reported, the following case may be of interest.

A man, aged 73, had for a year been vomiting and complained of difficulty in swallowing. X-ray examination of the œsophagus and stomach showed nothing abnormal. I attempted endoscopy 3 weeks before his admission to hospital, but I could not pass the œsophagoscope behind the cricoid cartilage. The day after his admission I tried again, and again had difficulty at the same place. After some time the instrument suddenly passed the cricoid cartilage, only to reveal loose connective-tissue instead of the œsophageal lumen. It was evident that I had perforated the posterosuperior part of the œsophagus, and shortly afterwards moderate subcutaneous emphysema appeared on both sides of the neck. Mouth feeding was stopped and nutrient enemas (250 g. daily) were given; subcutaneous saline (1 litre daily) and glucose saline (1 litre daily) were infused subcutaneously; and penicillin 25,000 units 3-hourly was started.

Except for slight tenderness on the right side of the neck there was no complaint, and 4 days later the subcutaneous emphysema had completely disappeared. The patient's temperature, however, immediately rose and remained between 100° and 102°F for the next week. The general condition was excellent; but despite complete absence of symptoms and signs a shadow at the base of the left lung was detected radiographically 6 days after the operation. Two days later the temperature rose to 102·8°F; tenderness at the right border of the larynx had increased a little, but there was no trace of infiltration or of air in the subcutaneous tissues, and laryngoscopy showed no abnormality. A mediastinal abscess was strongly suspected, and with local anæsthesia a collar mediastinotomy was done on the right side. The tissues were normal, but as my finger passed behind the cricoid cartilage into the mediastinum a large amount of pus and gas suddenly escaped. A rubber tube covered with gauze was introduced to the bottom of the cavity.

In 3 days the temperature fell to normal, but it soon rose again. Blood proteins and electrolytes, checked daily, were normal. During the ensuing days œdema appeared in the lower extremities and a hydrothorax developed on the left side; the chest was twice needled and 700 ml. of clear fluid evacuated. The patient died from heart-failure 24 days after the perforation.

Necropsy revealed a well-defined empty abscess cavity, 3·5–4 cm. in circumference, beginning behind and to the left of the œsophagus and reaching 15 cm. downwards, without any sign of communication with œsophagus, trachea, larynx, or plural cavities. In the œsophagus a carcinoma about 2 cm. in diameter was seen 3·5 cm. above the cardia. In the left pleural cavity 760 ml., and in the right 100 ml., of clear fluid was found; the lungs were œdematous. Between the layers of the pericardium adhesions, and in the coronary arteries arteriosclerosis, were noted; the valves were normal.

Goligher points out that "the anterior surface of the bony prominence provided by the cervical spine is seldom perfectly smooth, being marked by transverse ridges corresponding to the lower borders of the vertebral bodies, and in patients with spondylitis may be rendered extremely rough and irregular by the presence of pronounced osteophytes or spurs." In my case there was very pronounced spondylitis deformans with big exostoses along the borders of the cervical vertebræ; and these, together perhaps with not too skilful introduction, may have been responsible for the tear. I do not remember, 2½ years after the accident, the position of the head; but, though generally I pass the instrument neck flexed, I probably tried all positions to the difficulty encountered.

With our present knowledge it is obvious that case the amount of penicillin given (25,000 units 3- was insufficient; but even 100,000 units 3-hourly not prevent the formation of a mediastinal the fatal case reported by Goligher. He immediate suture of the tear, or, failing this, and drainage of the wound. Under similar I shall certainly follow his advice.

KARSTEN K

Frederiksborg County Hospital, Hillerød, Denmark.

Chief Surgeon, Ear, Throat Department.

ACCIDENTAL INTRA-ARTERIAL INJECTI DRUGS

SIR,—I was much interested in Mr. Cohen's on the danger of injections being given into ulnar arteries. Both my own ulnar arteries are ficial, and, when having injections, I have had to call attention to them. Perhaps an experienc clearing station in July, 1916, may be of interest:

> In a man with multiple injuries there were wounds forearms with hæmorrhage. The entry wound in the was in such a position that I remarked that time saved if the ulnar artery happened to be superficial: and so was the one in the right arm. The next p had a wound of the superficial ulnar, the abnormality one-sided. Then the anæsthetist looked at his own found he also had one.

Six superficial ulnars in four people at one in that rush the next patient was by the table his turn.

Liverpool. GEORGE C. E.

Obituary

SAMUEL WALTON WHEATON

M.D. LOND., F.R.C.P.

Dr. Samuel Wheaton, who died on Sept. 5 at of 86, was one of the few remaining medical of the old Local Government Board who had Simon and other founders of English State me

Wheaton qualified from St. Thomas's 1886, taking his M.B. Lond. with honours the year, and in 1888 his M.D. After holding an app as resident accoucheur at St. Thomas's H became physician to the Surrey Dispensary and Royal Hospital for Children and Women in the W Road. But in the midst of consulting practice interest was aroused in the new specialty of public —he had taken the D.P.H. in 1889—and in the '90s he became a full-time medical inspector of Local Government Board.

At first he was largely concerned with the epidemics and the improvement of sanitary tion, and to this period belong his notable enteric fever at Atherton, diphtheria at Hinckley, cholera at Ilkeston. Later under Sir Arthur N he was responsible for the administration of the new maternity and child-welfare service, and this included investigations into the incidence and of measles and pneumonia. Dr. Wheaton was also assessor to the Miners' Welfare Committee.

Sir Arthur MacNalty, who was associated Dr. Wheaton in his work at the board and lat the Ministry of Health, writes: "Samuel Wheaton a wise physician, and he brought clinical exper the service of public health. Though a little re in disposition, he was always courteous and consid With his bushy moustache and his broad-brimmed Wheaton looked rather like the conventional idea of artist, and in fact a large portion of his leisure spent in painting in oils. His pictures were often bited, and purple, blue, yellow, and green spla boldly on his canvas showed his mastery of vivid arresting colours. Even in the coldest of winters refused to have a fire in his room: for he maint is spartan way of life prevented the catching ."

06 Dr. Wheaton was elected to the fellowship of al College of Physicians. and from 1926 to 1928 he n their council.

THE LATE PROFESSOR JAMIESON

I add (M. J. S. writes) to the excellent pen of Jamieson drawn by two of his former colleagues columns something more about his life and work s. where for so many years he was an outstanding lity within and without the university? When to Leeds in 1910 Jamieson was still a demon- but that modest title gave no inkling of his g in the school. and that year, on Wardrop 's translation to the chair of medicine, he became full-time professor of anatomy in Leeds.

g his 15 years' apprenticeship as demonstrator he ked in close association not only with a physician- ist who was himself a brilliant teacher. but also succession of budding surgeons—Moynihan. J. F. , and William Gough—all of whom had been demonstrators in the department. It is not ng, therefore, that Jamieson's anatomical teaching loured by practical clinical considerations which reatly to its value, particularly in a school which ainly a training-ground for general practitioners geons. As a teacher he was supreme. His lectures tractive, lucid. and stimulating, but he was at t in the dissecting-room, where, even after he professor, he spent much of his time. Anatomy to attract or to breed good draughtsmen and good s, and his blackboard sketches were masterpieces racy and clarity.

ieson had a long and varied experience as an strator. His own department was exceedingly anaged and that without extravagance. In the years of his professoriate he was also warden of Hall. a hostel for men students. But it was the 1914–18 war that he had his first real tunity to show his capabilities. Professor de Burgh the dean of the medical faculty, was mobilised colonel of Territorials on the outbreak of war. son stepped into the breach. and for the next years deputised for him. In March. 1915, he was f commissioned as major and appointed registrar e East Leeds War Hospital, a big organisation began in part of the Township Infirmary in Beckett and later extended to other institutions inside tside the city. Later he was promoted lieut.- l and became administrator of the hospital. hile he continued to give part of his time to graduate teaching. These strenuous days brought nto closer contact with clinical colleagues and n other walks of life than ever before. He took a ular interest in the welfare of the non-commissioned s and men under his command—many of these me associates who turned to him for help in the ar period are grateful for what he did for them. of Jamieson's greatest pleasures was to take the at the annual reunion dinners of the hospital and rd the first round of drinks. He rarely missed a until he left Leeds in 1936.

1918, while still very fully occupied with his military . he was elected dean of the faculty of medicine airman of its board, complementary offices which d with distinction for 18 years of notable expansion. hool of dentistry (opened 1928), the extensions to partment of physiology (opened 1930), and the on Firth Institute of Pathology (opened 1933) all much to his energy and drive. From 1923 to 1925 s also pro-vice-chancellor of the university, and as eriod coincided with a long interregnum in the hancellorship Jamieson filled this office for the of the 1923–24 session.

received degrees from both the institutions which d served so well, the honorary LL.D. from Leeds 37, and later the M.A. and CH.M., jure officii. from College, Dublin. His portrait by Mr. Leo Whelan iblin. painted in 1937, is now in the medical school at Leeds.

mieson had his own, sometimes unorthodox, methods rking. He was much given to writing memoranda on problems of the hour. These were never typed. except when duplication was essential, but were written in his own clear firm hand. Many of his colleagues have had reason to be grateful for these admirable documents. setting forth in lucid sentences the opinions of a man of vision and sound common sense. He never had a private secretary. The secretary of the school. or dean's clerk, as he was then called, had his own particular duties assigned to him—with a typewriter but no stenographer. Most of Jamieson's memoranda were written, not in the dean's office. which was much too public a place. but either in his own little sanctum with its private stair in the anatomy department or at home during the midnight hours.

In private life, despite certain appearances to the contrary, Jamieson was a sociable and friendly man. Like most people he had his antipathies. but fundamentally he was fair and tolerant, if given at times to the free and forcible expression of critical opinions. No teacher ever held a more assured place in the affection of his students. and his colleagues mourn the passing of a great teacher, a capable administrator and a loyal. warm-hearted. and courageous friend.

A memorial service for the late Mr. J. E. H. Roberts. consulting surgeon to St. Bartholomew's Hospital, will be held in the Church of St. Bartholomew-the-Less. West Smithfield, E.C.1. on Tuesday. Sept. 21. at 1 P.M.

Births, Marriages, and Deaths

BIRTHS

Adkins.—On Sept. 6, the wife of Mr. E. W. O. Adkins, F.R.C.S.—a daughter.
Hardwick.—On Sept. 3, in London, the wife of Dr. S. W. Hardwick—a daughter.
Henegan.—On Sept. 5, the wife of Dr. Donald Henegan—a son.
Kelly.—On Aug. 30, at Boscombe, the wife of Dr. Reginald Kelly—a son.
Leeson.—On Sept. 12, to Dr. Jean Leeson (née Mackay), wife of Dr. C. A. Leeson—a daughter.
McCall.—On Sept. 9, at Tunbridge Wells. the wife of Dr. Michael McCall—a daughter.
Pearse.—On Sept. 4, in London, the wife of Dr. A. E. Pearse—a son.
Punt.—On Sept. 14, in London, the wife of Dr. Norman A. Punt, F.R.C.S.E., D.L.O.—a son.
Ross.—On Sept. 5, in Edinburgh. the wife of Mr. James A. Ross. M.B.E., F.R.C.S.E.—a daughter.
Taylor.—On Sept. 6, in London, the wife of Dr. G. R. Taylor—a daughter.
White.—On Sept. 7, the wife of Dr. A. A. White—a son.
Wilson.—On Sept. 5, at Ludham, Norfolk, the wife of Dr. Peter Wilson—a daughter.

MARRIAGES

Brown—Hardy.—On Aug. 27, at Great Sampford. Essex, Wilfred Stuart Brown, M.R.C.S., to Betty Stella Hardy.
Livingston—McDonagh.—On Sept. 9, in Jamaica, Sir Noel Brooks Livingston, to Josephine Olga McDonagh. M.R.C.S.
Mathewson—Tierney.—On Sept. 4, in London, John Gray Mathewson, M.B., to Jane Tierney.

DEATHS

Banks.—On Sept. 9, at Hadlow Down. Sussex, Alfred Banks, F.R.C.S., D.P.H., aged 86.
Kempster.—On Sept. 7, in London, Christopher Richard Kempster, M.R.C.S.
Pulling.—On Sept. 9, at Brighton, Herbert John Pulling. M.R.C.S., aged 88.
Soni.—On Sept. 7, in Manchester, Mul Raj Soni, B.A. Punjab. M.B. Edin., D.P.H.
Willis.—On Sept. 12, at Cheadle, Cheshire, Eugenie Leeson Willis. M.A., M.B. Camb., F.R.C.S.

country any earth is taken to another country and a viper is encircled with it, the viper cannot escape from this imprisoning ring until it dies."

Spain's greatest writer of all time spoke here, as always, in friendly and sympathetic terms of England.

Santa Cruz de Tenerife. JOSE DURAN MOLINA.

POSTCRICOID PHARYNGO-ŒSOPHAGEAL PERFORATION DUE TO ENDOSCOPY

SIR,—*In his article of June 26 (p. 985) Mr. Goligher* discussed œsophageal and pharyngeal perforation during gastroscopy and œsophagoscopy. Most often perforation is the direct result of this operation, and takes place at the site of the pathological condition for which endoscopy has been undertaken. Occasionally, however, it is produced in the postcricoid region, at a point remote from the primary lesion. As only a few of these accidents have been reported, the following case may be of interest.

A man, aged 73, had for a year been vomiting and complained of difficulty in swallowing. X-ray examination of the œsophagus and stomach showed nothing abnormal. I attempted endoscopy 3 weeks before his admission to hospital, but I could not pass the œsophagoscope behind the cricoid cartilage. The day after his admission I tried again, and again had difficulty at the same place. After some time the instrument suddenly passed the cricoid cartilage, only to reveal loose connective-tissue instead of the œsophageal lumen. It was evident that I had perforated the posterosuperior part of the œsophagus, and shortly afterwards moderate subcutaneous emphysema appeared on both sides of the neck. Mouth feeding was stopped and nutrient enemas (250 g. daily) were given; subcutaneous saline (1 litre daily) and glucose saline (1 litre daily) were infused subcutaneously; and penicillin 25,000 units 3-hourly was started.

Except for slight tenderness on the right side of the neck there was no complaint, and 4 days later the subcutaneous emphysema had completely disappeared. The patient's temperature, however, immediately rose and remained between 100° and 102°F for the next week. The general condition was excellent; but despite complete absence of symptoms and signs a shadow at the base of the left lung was detected radiographically 6 days after the operation. Two days later the temperature rose to 102·8°F; tenderness at the right border of the larynx had increased a little, but there was no trace of infiltration or of air in the subcutaneous tissues, and laryngoscopy showed no abnormality. A mediastinal abscess was strongly suspected, and with local anæsthesia a collar *mediastinotomy was done on the right side. The tissues* were normal, but as my finger passed behind the cricoid cartilage into the mediastinum a large amount of pus and gas suddenly escaped. A rubber tube covered with gauze was introduced to the bottom of the cavity.

In 3 days the temperature fell to normal, but it soon rose again. Blood proteins and electrolytes, checked daily, were normal. During the ensuing days œdema appeared in the lower extremities and a hydrothorax developed on the left side; the chest was twice needled and 700 ml.. of clear fluid evacuated. The patient died from heart-failure 24 days after the perforation.

Necropsy revealed a well-defined empty abscess cavity, 3·5–4 cm. in circumference, beginning behind and to the left of the œsophagus and reaching 15 cm. downwards, without *any sign of communication with œsophagus, trachea, larynx,* or plural cavities. In the œsophagus a carcinoma about 2 cm. in diameter was seen 3·5 cm. above the cardia. In the left pleural cavity 760 ml., and in the right 100 ml., of *clear* fluid was found; the lungs were œdematous. Between the layers of the pericardium adhesions, and in the coronary arteries arteriosclerosis, were noted; the valves were normal.

Goligher points out that "the anterior surface of the bony prominence provided by the cervical spine is seldom perfectly smooth, being marked by transverse ridges corresponding to the lower borders of the vertebral bodies, and in patients with spondylitis may be rendered extremely rough and irregular by the presence of pronounced osteophytes or spurs." In my case there was very pronounced spondylitis deformans with big exostoses along the borders of the cervical vertebræ; and these, together perhaps with not too skilful introduction, may have been responsible for the tear. I do not remember, 2½ years after the accident, the position of the head; but, though generally I pass the instrument neck flexed, I probably tried all positions to ov the difficulty encountered.

With our present knowledge it is obvious that case the amount of penicillin given (25,000 units 3 h was insufficient; but even 100,000 units 3-hourly not prevent the formation of a mediastinal a the fatal case reported by Goligher. He s immediate suture of the tear, or, failing this, and drainage of the wound. Under similar con *I shall certainly follow his advice.*

ACCIDENTAL INTRA-ARTERIAL INJECTIO DRUGS

SIR,—I was much interested in Mr. Cohen's re on the danger of injections being given into ab ulnar arteries. Both my own ulnar arteries are ficial, and, when having injections, I have had oc to call attention to them. Perhaps an experience clearing station in July, 1916, may be of interest:

In a man with multiple injuries there were wounds forearms with hæmorrhage. The entry wound in the le was in such a position that I remarked that time w saved if the ulnar artery happened to be superficial: and so was the one in the right arm. The next pati had a wound of the superficial ulnar, the abnormality one-sided. Then the anæsthetist looked at his own found he also had one.

Six superficial ulnars in four people at one tim in that rush the next patient was by the table read his turn.

Obituary

SAMUEL WALTON WHEATON

M.D. LOND., F.R.C.P.

Dr. Samuel Wheaton, who died on Sept. 5 at t of 86, was one of the few remaining medical ins of the old Local Government Board who had Simon and other founders of English State medic

Wheaton qualified from St. Thomas's Hospit 1886, taking his M.B. Lond. with honours the fo year, and in 1888 his M.D. After holding an appoin as resident accoucheur at St. Thomas's Hospi became physician to the Surrey Dispensary and t Royal Hospital for Children and Women in the Wat Road. But in the midst of consulting practice interest was aroused in the new specialty of public h —he had taken the D.P.H. in 1889—and in the '90s he became a full-time medical inspector of Local Government Board.

At first he was largely concerned with the control epidemics and the improvement of sanitary admi tion, and to this period belong his notable repo enteric fever at Atherton, diphtheria at Hinckley, cholera at Ilkeston. Later under Sir Arthur Newsh he was responsible for the administration of the b new maternity and child-welfare service, and this included investigations into the incidence and mort of measles and pneumonia. Dr. Wheaton was also assessor to the Miners' Welfare Committee.

Sir Arthur MacNalty, who was associated Dr. Wheaton in his work at the board and late the Ministry of Health, writes: "Samuel Wheaton a wise physician, and he brought clinical experience the service of public health. Though a little r in disposition, he was always courteous and conside With his bushy moustache and his broad-brimmed Wheaton looked rather like the conventional idea of artist, and in fact a large portion of his leisure spent in painting in oils. His pictures were often e bited, and purple, blue, yellow, and green splas boldly on his canvas showed his mastery of vivid arresting colours. Even in the coldest of winter refused to have a fire in his room: for he maintai

CUTE BACTERIAL ENDOCARDITIS *

CRIGHTON BRAMWELL
M.A. Camb., M.D. Manc., F.R.C.P.
OR OF CARDIOLOGY IN THE MANCHESTER UNIVERSITY

successful treatment of subacute bacterial endo- with penicillin is one of the most remarkable es in therapeutics in recent years. Five years ago s an incurable disease; no known drug, not even phonamides, could influence its course. though it ed that spontaneous recovery took place occa- . Now we may expect to control the infection in ases, provided diagnosis is not unduly delayed.

cute bacterial endocarditis is a common cause of in patients with chronic rheumatic heart disease ngenital heart disease. Laws and Levine (1933) that it was responsible for death in 29% in their of cases of rheumatic heart disease, and Abbott stated that it was the cause of death in 33% of ts with congenital heart disease.

1944 the Medical Research Council initiated, at centres in Britain, an investigation of the treat- of this disease with penicillin, and Christie (1948) ported the results obtained in 269 cases so treated. partment in Manchester participated in this investi- , and the present paper is based on the first 50 re treated. These may be divided into two groups:

t Series.—33 cases treated before June, 1946, and ed by my colleagues Jones et al. (1947). This may be ed as a fair average sample of the disease. All 33 cases ow been followed up for not less than two years.

nd Series.—17 cases treated since July, 1946. These a rather different category, for many of them had sly failed to respond to treatment elsewhere, and must re be regarded as less favourable from the therapeutic

DIAGNOSIS

is convenient to subdivide bacterial endocarditis acute and subacute. Some cases may be regarded onic, but these do not appear to differ ætiologically those classed as subacute, and clinically there is no dividing line between the two.

ate endocarditis does not concern us here—it ther to be regarded as a complication of some disease. In pneumonia, for example, Luxton and (1943) have shown that bacterial endocarditis is less rare than is generally supposed. It may be portant cause of death, but it generally escapes nition during life, its manifestations being over- wed by those of the more obvious pulmonary lesion. acute cases, in which the infecting organism is only a hæmolytic streptococcus, a staphylococcus, umococcus, or a gonococcus, run a rapid course and ally prove fatal within two months.

subacute bacterial endocarditis, on the other hand, ite of primary infection is in the heart itself, the disease a more chronic course, and, in the great majority of the organism concerned is *Strep. viridans.*

e principal clinical features on which we are accus- d to base a diagnosis of subacute bacterial endo- tis are a valvular lesion or congenital defect, pyrexia, lic phenomena, splenomegaly, and a positive l-culture.

e Pre-existing Lesion.—The orthodox view, in the has been that subacute bacterial endocarditis y attacks a heart which has not previously been ged by rheumatic infection or is the seat of some nital abnormality, but it is remarkable that the xisting heart disease is almost always trivial, and patients with advanced heart disease appear to be une. For example, auricular fibrillation was present in only one of the 33 patients in our first series and in only 5 of Christie's (1948) 269 cases. Likewise none of our patients gave a history of heart-failure before infection. and in only 3 had there been any considerable impairment of capacity for effort; even these 3 carried on their normal activities. Of the remainder, 17 were in employment, and 11 women looked after their homes and families. The other 2 patients were still at school or college. In 13 of our patients there was a complaint of dyspnœa on unusual exertion but not during ordinary activity, while in 17 there had been no impairment of exercise tolerance and 8 of these did not even know that they had heart disease.

Of our 33 patients, 29 had rheumatic heart disease, but in 11 of them systolic murmurs only were present on admission. So rarely does one hear a typical crescendo presystolic murmur in bacterial endocarditis that its presence is sufficient to make one question the correctness of the diagnosis. Of our 12 rheumatic cases that came to necropsy in 2 only had the mitral disease produced stenosis. Aortic incompetence, on the other hand. was common, being diagnosed clinically in 16 of the 29 rheumatic cases. Coombs (1922–23) and Starling (1922–23). in their papers on chronic bacterial endocarditis amongst ex-Servicemen from the 1914–18 war, both remark on the rarity of a history of rheumatism and on the fact that often there was no evidence of previous cardiac damage.

Pyrexia.—Unexplained pyrexia in a patient with chronic heart disease is a pointer, and may be the only pointer, to the diagnosis of subacute bacterial endocarditis. It calls for immediate blood-culture. On the other hand, the absence of pyrexia does not exclude the possibility of infection, for in the more chronic type of case there may be long apyrexial periods. In one patient who was under my care in hospital some years ago, and in whom the diagnosis of subacute bacterial endocarditis was confirmed at necropsy, the temperature never rose above normal during the last nine weeks of life. The possible absence of pyrexia has been emphasised by both Coombs (1922–23) and Starling (1922–23).

Embolic Phenomena.—Major embolic phenomena may involve either the arteries of the limbs or those of the internal organs. In our series cerebral, splenic, renal, and coronary arteries were involved. Minute emboli lodging in the skin or subcutaneous tissues produce petechial hæmorrhages and Osler's nodes, whereas those lodging in the glomeruli of the kidney are one of the causes of hæmaturia in this disease.

Splenomegaly may be due either to infarction or to toxæmia. In the past most clinicians have taught that in congestive heart-failure the spleen is rarely palpable, and that in chronic valvular disease clinical enlargement of the spleen indicates infection. Fowler (1947), however, has brought forward evidence based on necropsy findings that the spleen may be considerably enlarged in heart-failure associated with rheumatic valvular disease. Taking 200 g. as the upper limit of normal and 300 g. as the lower limit of palpability, in 15% of his cases of congestive failure the spleen should theoretically have been palpable. though in only one case had it actually been felt during life.

Blood-culture.—Libman (1913), Osler (1908–09). Horder (1908–09), and the earlier workers generally were of opinion that in this condition blood-culture often proved negative. With the improved modern technique it is our experience that a positive blood-culture is obtained on the first attempt in the great majority of cases. In the 50 cases in our combined series the organism was isolated in the first blood-culture in 43, in the second in 5, in the fourth in one, and in the remaining case a positive culture had previously been obtained in another hospital. The technique is important and has been described by Penfold et al. (1940). In 5 cases in which, before the

ed on a paper read at the Derby Medical Society on March 16, 918, with further follow-up of cases to June, 1948.

Notes and News

PROF. JÖRGEN SCHAUMANN

ONE of the kindliest possible gestures has lately been made in honour of Professor Schaumann; a committee of fifteen clinicians has published a golden book [1] in his honour, and has persuaded Prof. Henri Gougerot, of Paris, to contribute a foreword setting Schaumann's work in its correct perspective. The work was to have been issued to celebrate Schaumann's 60th birthday, "mais les événements de l'époque ne permettaient pas de donner une suite immédiate à ce projet." The book contains over sixty reprints of articles which have appeared either in *Acta Dermato-Venereologica* or in *Acta Medica Scandinavica*; it is, of course, chiefly concerned with benign lymphogranuloma (Schaumann's disease) and with kindred topics. While Schaumann must feel pleasure in this well-merited distinction, others can be grateful for such a useful compilation of the writings of many eminent authorities now republished to honour one of the most progressive thinkers in modern European medicine.

REPRODUCTION EXPLAINED TO CHILDREN

Dr. Edward F. Griffith's *The Truth about the Stork* [2] is a good idea which does not quite come off. It was a useful inspiration that made him set out to describe human reproduction in clear, open, and easy terms to children; but he seems to be in some doubt about the age of the child he is enlightening. The book begins with anatomy and physiology explained in words suitable for a child of seven, but accompanied by pictures and diagrams which would be better understood by a ten-year-old. Again, these more or less scientific diagrams and photographs are interspersed with comic drawings of rabbits, germs, and Noah's ark only suitable for tiny children. Mating is simply described, and so is normal birth, but it seems unnecessary to go on, in a book of this kind, to breech birth, cæsarean section, abortion and miscarriage, venereal disease, sterility, and birth-control. These are subjects for the adolescent, not the young child—unless for some reason he asks questions, or has been frightened by something he does not understand, such as a miscarriage in his own family. Dr. Griffith, on thinking things over, may be inclined in future editions to turn his one book into two.

University of London

Prof. J. R. Learmonth has been appointed Heath Clark lecturer for 1949. He has chosen as his subject the Contribution of Surgery to Preventive Medicine.

University of Sheffield

On Wednesday, Oct. 13, Lord Horder will deliver the opening sessional address of the faculty of medicine, in the Firth Hall of the university at 3 P.M. His subject will be the Vocation of Medicine.

University of Glasgow

Prof. Geoffrey Jefferson, F.R.S., will deliver the Macewen lecture in the chemistry building of the university on Friday, Oct. 1, at 3 P.M. He has chosen as his subject the Contribution of Sir William Macewen to Neurosurgery and Its Sequels.

University of Aberdeen

Dr. H. W. Fullerton has been appointed to the regius chair of medicine in succession to Prof. R. S. Aitken who has been appointed vice-chancellor of the University of Otago.

Dr. Fullerton took his M.A. at Aberdeen in 1925 and his M.B. in 1931. In 1937 he obtained his M.D. with honours and four years later took the M.R.C.P. After holding a house-appointment at Aberdeen Royal Infirmary he was awarded successively Rockefeller and Beit fellowships. He is at present lecturer in medicine at Aberdeen and an assistant physician at the Royal Infirmary. He has published papers on the nutritional anæmias.

Royal College of Physicians of London

On Tuesday and Thursday, Oct. 12 and 14, at 5 P.M. at the college, Pall Mall East, S.W.1, Dr. Desmond Curran will deliver the Croonian lectures. He is to speak on Prefrontal Leucotomy.

Royal Faculty of Physicians and Surgeons of

At a meeting of the faculty held on Sept. 6, with G. B. Fleming, the president, in the chair, the following admitted to the fellowship:

John Bell Cochran, John Ernest Awelrydd David, Mohanlal Desai, Thomas Jack, Patrick MacArthur, Ronald MacGillivray, William Greer Manderson, Ralph Adair Brown, Nathan Sher (qua physicians); John Thomson Buchan, Reginald Wheeler Busschau, Thomas Lightbody George Logan Clark, James Ross Hutchinson, Jacob Daniel Anandlal B. Kothari, William Sommerville Mack, Fred Inglis MacLeod, Aaron Meyer Porter, William Rankin, C Slight, William Barr Stirling, Alfred Edward Wilkinson, Brash Wright (qua surgeons).

King's College Hospital

Prof. Henry Cohen will deliver the inaugural the session at the medical school on Friday, Oct. 1, at

Westminster Hospital

The old students' annual dinner will be held this the Savoy Hotel on Saturday, Oct. 2, at 7.45 P.M. Arnold Stott will be in the chair.

Middlesex County Medical Society

At a meeting of this society to be held at 4 P.M. Friday, Sept. 17, at the North Middlesex County Silver Street, Edmonton, N.18, Mr. Ivor Lewis will address on Diagnosis.

International Scientific Film Congress

In connexion with this congress an exhibition of ill and photographs from teaching hospitals is to be 1, Wimpole Street, London, W.1, from Oct. 6 to 11 exhibition is designed to interest medical teachers.

West London Medico-Chirurgical Society

A dinner of this society will be held on Friday, Oct. the South Kensington Hotel, 41, Queen's Gate Terrace, at 7.30 P.M. At 8.30 P.M. Dr. W. S. C. Copeman wi presidential address on West London Worthies, a

British Hospitals Contributory Schemes

The final conference and annual general meeting association will be held at the Majestic Hotel, F from Sept. 30 to Oct. 3. Mr. Aneurin Bevan will be the of honour at the dinner on Oct. 1, and the concluding of the meeting will be to receive a report for the new which it is proposed to establish.

Chadwick Lectures

The autumn programme of the Chadwick Trust lectures by Sir Arthur MacNalty on Advances in F Medicine during the War of 1939–45 (Nottingham College, Oct. 28, 4 P.M.), by Dr. Wyndham Lloyd Prevention of Tuberculosis with special reference to ment (Westminster Hospital medical school, S.W.1, 2.30 P.M.), and by Dr. Charles Seeley on Preventive and Clinical Medicine in relation to the Public He Mary's Hospital medical school, W.2, Dec. 2, 4.30 Further particulars may be had from the secretary of 204, Abbey House, Westminster, S.W.1.

CORRIGENDA.—*Industrial-health Courses at M* The reference to these courses in the Students' Guide was incomplete. Courses for the D.I.H. are held each Manchester University, which was the first to offer a course for this diploma.

In the list of centres for the distribution of strept (*Lancet*, Sept. 11, p. 428) the telephone number of Park Hospital should be Lee Green 1077.

vious occupations without any evidence that acity for exertion has deteriorated; one is not since there is no economic necessity for her to ne is receiving treatment for a reinfection; and ıbjectively deteriorated and are unfit for work. st 3 are the only patients in whom cardiac ent was progressive after the end of treatment. f them, in whom only an aortic lesion had been signs of mitral stenosis developed, and in the the cardiogram showed an increased tendency axis deviation. These changes suggest that in es, even after the infection has been controlled in the process of healing—a stenotic valvular ay develop or increase in severity; thereby an additional and progressively increasing n the heart.

PROGNOSIS

on of Infection.—The most important factor in s appears to be the duration of infection before it. In our first series, when symptoms had been for less than ten weeks before treatment was o patient died, whereas none with symptoms or thirty weeks or more recovered. A similar is apparent in the combined series (Christie ough the contrast is less striking. From these he importance of early diagnosis is obvious. The reatment is started, the greater is the prospect of

tunately at this stage of the disease diagnosis extremely difficult, for the initial symptoms of l endocarditis give little indication of the nature ıfection; in our cases the commonest presenting were lassitude, generalised "rheumatic" pains, developing in patients already under observation, ue illness resembling influenza. In 3 cases major accidents marked the onset of symptoms: f them a subarachnoid hæmorrhage was presum- e to rupture of a mycotic cerebral aneurysm; cond hæmoptysis from a pulmonary infarct led staken diagnosis of pulmonary tuberculosis; and hird visible hæmaturia and loin pain from a large ıfarct suggested a urinary calculus. Persistent g or pallor were the presenting symptoms in In the more chronic type of bacterial endocarditis d by Starling (1922–33) anæmia was a much more nt symptom, the average hæmoglobin value in s being only 55%, but in these cases infection bably been present for a longer time when the s first came under observation.

ralised "rheumatic" pains were a common symp- our patients. They were of sudden onset but , and were rarely confined to the joints but often l muscle masses in the limbs or trunk. Such pains to lead to a mistaken diagnosis of "rheumatism" of rheumatic fever.

—Christie (1948) states that "age was of doubtful stic significance, except in the group over 50." In mbined series there were 9 patients over 50, 3 m are still living. The higher mortality among er patients may be partly due to the fact that in he condition is more apt to escape recognition, the infection remains untreated for a longer time.

t-failure.—As I have already remarked, the sting heart lesion, whether rheumatic or con- , is usually trivial, and it is not until infection en present for a considerable time that heart- appears. When it is present it adds greatly to vity of the prognosis (see below).

ition.—Christie (1948) emphasises the importance state of nutrition as a factor in prognosis, and the r a high-calorie diet, as in other protracted fevers. gnificance of nutrition appears to be independent duration of infection or of the incidence of failure.

CAUSE OF DEATH

Of the 33 patients in our first series 15 died, 8 during or within a few days of the end of treatment, the other 7 between four and thirteen weeks after treatment. In the whole series of 269 cases (Christie 1948) there were 131 deaths.

In those who died during treatment infection was considered to be wholly responsible for death in one case and partly responsible in 4. In no case in which death took place after treatment was there any evidence that infection played a part in the fatal issue.

Heart-failure was directly responsible for death in 5 of our 15 fatal cases and was a contributory cause in 5 others. Heart-failure usually developed when considerable cardiac enlargement was present, and there was a definite relation between (1) heart size and death-rate, and (2) heart size and duration of infection before treatment. Patients with large hearts generally gave a history of symptoms of infection lasting over many weeks whereas those without cardiac enlargement had been ill a shorter time. This direct relation between the duration of the bacterial endocarditis and the heart size suggests that cardiac damage due to the infection plays an important part in producing cardiac enlargement and heart-failure

Admittedly, various degrees of cardiac enlargement were present before infection, but the high degree of cardiac efficiency in most of our patients before infection suggests that their cardiac lesions were comparatively trivial, and that most of the cardiac damage was due to the subsequent infection.

Recovery was the exception in those who developed failure and the rule in those who did not. At the onset the failure was usually left-sided. Both myocardial and valvular damage due to the infection were factors in producing failure, but the mechanical stress from valvular lesions probably played the more important part.

Major vascular accidents, cerebral hæmorrhage in 2 cases and pulmonary embolism in one, were the cause of death in 3 of our cases. In one of these the fatal hæmorrhage appeared to be attributable to cerebral embolism which had occurred twelve months earlier.

Renal complications were considered to be partly responsible for death in 4 of our patients, 3 of whom died before the end of treatment.

PREDISPOSITION

In our first series there were 11 men and 22 women, and it is remarkable that in 7 of the women infection developed during pregnancy. The first 2 of these, in whom infection had been present for a considerable period before treatment was begun, both died; the other 5 were treated early and did well in spite of major vascular accidents in 2 and heart-failure in one. In one case a macerated fœtus was expelled a few days before the beginning of treatment, the other six children are well. Thus, provided the infection is promptly detected and adequately treated, the prognosis is good for both mother and child; and since, owing to the association of heart disease with pregnancy, these patients are usually under supervision at the time infection occurs, there is every opportunity for early diagnosis.

This very high incidence of subacute bacterial endocarditis during pregnancy calls for explanation. It is true that, in my clinic, we are particularly interested in heart disease associated with pregnancy, and that the material passing through our maternity hospital is carefully screened from this point of view; but, even making allowance for this, we feel that some other predisposing factor must be involved, and that in this disease, as Coombs (1922–23) suggested, the soil may be even more important than the seed.

The high incidence in pregnant women recalls the high incidence of "endocarditis lenta" among Army patients came under our care, repeated blood-cultures had been negative we were able to isolate the organism.

To observe the response to penicillin it was important that only proved cases of subacute bacterial endocarditis should be treated. Hence, for this investigation, cases in which we failed to obtain a positive blood-culture were excluded from the series. While these observations were in progress, 4 such cases, which clinically were regarded as subacute bacterial endocarditis, were admitted to my wards. In 2 of these, in view of the gravity of the patient's condition, treatment with penicillin was started after only one blood-culture had been taken. Of these 4 patients 2 died, and in them the diagnosis of bacterial endocarditis was confirmed at necropsy; the other 2 recovered.

To sum up, therefore, in 52 proved cases of bacterial endocarditis, a positive blood-culture was obtained on the first attempt in 44, on the second in 5, and on the fourth in one, while in 2 cases blood-culture proved negative. There remain 2 cases in which the diagnosis seemed highly probable on clinical grounds but in which blood-culture was negative. If we accept these 2 as bacterial endocarditis, blood-culture was positive in 50 and negative in 4, in 2 of which only a single culture was taken.

Patent Ductus.—I cannot leave this aspect of the subject without referring to a group of cases of special interest, in which the underlying lesion is a patent ductus. In such cases, of which there were 2 in our series, both children, the embolic phenomena involve the pulmonary instead of the systemic circuit, producing recurrent pulmonary emboli. The importance of this group, as Gilchrist (1948) has shown, is that the infection can often be controlled by ligature of the ductus without penicillin, though in patients who are gravely ill a course of penicillin may diminish the surgical risk.

TREATMENT

Early in this investigation it became evident that the duration of treatment was of great importance. Of 52 patients (Christie 1948), all given 5 mega-units of penicillin, 83% relapsed or died infected when the treatment lasted only five days, compared with 50% of those who were given the same total quantity of penicillin in ten days, and 22% of those in whom the period of treatment was twenty days. Later it was found that a dose of 0·5 mega-unit daily for twenty-eight days was sufficient to control the infection in 90% of patients. This was the dose given in all but 3 of the patients in our first series who lived to complete treatment.

We have usually given penicillin by three-hourly intramuscular injection, and this has been well tolerated for long periods. In 5 cases we used a continuous intramuscular drip, changing the site every twenty-four hours; but in each case, after a few days, we were obliged to resort to injection owing to severe pain at the site of the drip and the development of pyrexia. In all these cases the penicillin was of the less purified type, and we have not tried this method with the more highly purified preparations now obtainable.

The progress during treatment in a typical successful case may be summarised as follows:

> The temperature falls to normal within a few days, but the pulse-rate takes much longer to settle. The patient should be confined to bed for three weeks after the end of treatment, though the temperature and pulse-rate are normal. Carefully graduated and cautiously applied bed exercises are then started, and about ten days later the patient is allowed up for a short time. Great care is necessary during the early period of rehabilitation following successful treatment, however well the patient may appear to be when resting in bed. In fact we regard gradual rehabilitation in this disease as no less important than in myocardial infarction, undue haste being likely to lead to heart-failure.

Though infection can usually be controlled by a single course of treatment lasting only twenty-eight days, it takes much longer for the erythrocyte-sedime rate (E.S.R.), the anæmia, and the weight to ret normal. In our successful cases the E.S.R. did not normal until about five weeks after the end of treat There was often little rise in the hæmoglobin pe during treatment, but subsequently steady improv took place and a normal level was attained, transfusion, about three months after the end of ment; a gain in weight continued up to nine after treatment. In 8 of our successful cases th in weight averaged 23 lb.

Convalescence in these patients is slow and careful management. In our cases the average hospital was fourteen weeks; full activity wa resumed sooner than six months after the e treatment.

In cases in which the infecting organism is resistant to penicillin, Christie (1948) has suggested 2 mega-units daily should be given for six or eight of only four weeks, but we have not yet made observations to assess the efficacy of this dosage.

In one of the patients in our second series in the organism was known to be highly resistant larger doses were given; but, though these tem controlled the infection, a relapse occurred on occasion when the penicillin was discontinued.

> This patient had been treated elsewhere with the routine course of 0·5 mega-unit for twenty-eight day had not responded. In his second course of treatment, lasted eighty days, we started with 1 mega-unit dai subsequently increased this to 3 and later to 8 mega It was only on 8 mega-units that blood-culture negative. After relapse, a third course was given, of 12 mega-units daily for twenty-nine days. This c the infection, but four days after the completion of thi the patient again relapsed, and died two months late man received a total of 720 mega-units in six months.

In several of our cases, though the temperature h normal after treatment had begun, it rose again a beginning of the second week, and an inte pyrexia persisted until the penicillin therapy wa continued, when, in every case, the temperature normal. At first we were inclined to suspect t pyrexia indicated failure to control the infection, therefore doubled the dose of penicillin, but, ins falling, the temperature then rose higher. These o tions led us to conclude that, when the temperatu to normal in the first week, a subsequent rise i second week is a drug fever.

The only other toxic manifestations of penicilli our series were urticarial rashes in 2 cases and thr cytopenia in 2 others.

RESULTS

Of the 33 patients in our first series 15 died and 18 alive. Of those alive 15 are free from infection two or more after the end of treatment; one is at work has not been re-examined; one has recently recei course of treatment in a London hospital after rein with a different organism; and one has been read with a reinfection following a dental extraction perf without penicillin cover.

We feel hopeful therefore that most of these case prove to be permanently cured, for Christie's (figures show that 90% of relapses occur within a of the end of treatment. In our first series, in treated with a full course of 0·5 mega-unit for tw eight days there were 2 reinfections (see above) b relapses. In our second series, 3 patients did not re to penicillin, and there have been 2 relapses. Of patients who relapsed one died infected; and in other blood-cultures were negative for fifteen before death from heart-failure.

The degree of recovery can be gauged from the that, of our 18 patients who survived, 13 have res

MOPHILUS INFLUENZÆ MENINGITIS TREATED WITH STREPTOMYCIN

P. M. SMYTHE
M.B. Camb., M.R.C.P.
ST ASSISTANT AND REGISTRAR TO THE CHILDREN'S
DEPARTMENT, THE LONDON HOSPITAL

TIL recently *Hæmophilus influenzæ* meningitis was ly fatal. Duncan and Webb (1934) found only 27 eries reported, 70% of them being in patients over ge of 2 years. A slight improvement followed the duction of sulphonamides and Fothergill's horse n, but results remained unsatisfactory. The first advance was Alexander's combined therapy with adiazine and specific anti-influenza-B rabbit serum. g this method she reported 68 recoveries out of ases (Alexander 1944), Smith et al. (1946) 24 eries out of 27, Beck and Janney (1947) 19 out , and Turner (1945) 10 out of 20.

e introduction of streptomycin was a further nce. The National Research Council (1946) reported ecoveries out of 100 cases, but some of these had ived combined therapy; Weinstein (1946) 7 out of 9; Alexander et al. (1946) 18 out of 21, 3 of whom not controlled by streptomycin and were given it serum and sulphonamides as well.

enicillin in conjunction with sulphonamides has also used, particularly in this country. The largest s so treated is that of Zinnemann (1946) who reported coveries out of 15 cases. I record here the results 2 cases transferred to the London Hospital for treatit with streptomycin. In 10 of them penicillin or honamides had been administered before admission; these drugs had not controlled the infection and *nfluenzæ* was still present in the cerebrospinal fluid F.) or blood.

osage and Treatment.—A routine of treatment was owed in conformity with the recommendations of Medical Research Council committee for streptocin trials in non-tuberculous conditions. All the ients received about 20 mg. of streptomycin per body-weight daily, divided into six intramuscular injections, together with a daily intrathecal injection of 25–100 mg. in 5 ml. of saline, the dose varying with the age of the patient and the severity of the disease. Treatment by both routes was continued until the C.S.F had been sterile for at least a week. No other specific treatment was given unless there was no response to streptomycin. Blood-transfusions were given when indicated for anæmia. Feeding was by œsophageal tube if there was any disturbance of consciousness.

Streptomycin Levels.—The methods of titration of streptomycin in blood-serum and C.S.F. were in accordance with Medical Research Council's instructions (M.R.C. 47/241, May 8, 1947). In 2 cases the serum-streptomycin level was estimated. An hour after the intramuscular injection of 80 mg. the concentration was 8–16 units per ml., and four hours after injection 2–4 units. The C.S.F.-streptomycin levels estimated twenty-four hours after intrathecal injection are shown in table I. After the injection of 25–50 mg. the level was usually 8–16 units per ml., and after 100 mg. it was 32–64 units per ml.

Toxicity.—Streptomycin caused no toxic effects, and there were no reactions from intrathecal instillation. One child (case 8) appears to be moderately deaf after a nine-day course of streptomycin, but whether this resulted from the drug or the meningitis, or both, it is impossible to say.

Bacterial Sensitivity.—In estimating sensitivity of *H. influenzæ* to streptomycin two methods were used. At first the minimal inhibiting concentration of the drug in Fildes's broth was estimated. This was 1 unit per ml. in 2 cases, and 2 units in 1 case. It was soon recognised that the results obtained by this method varied considerably with the size of the inoculum and the constitution of the medium. Latterly two drops of a solution containing 100 units of streptomycin per ml. was placed in a cup in the agar plate, and the diameter of the surrounding zone of inhibition was measured. This was done in the remaining 8 cases from which an organism was grown, and the zone of inhibition in these was 15–23 mm. in diameter.

Sensitivity tests were repeated whenever organisms reappeared in the C.S.F. In 3 cases that relapsed the

pensioners after the 1914–18 war. When I was medical registrar at the Manchester Royal Infirmary in 1920–23, this disease was so common among ex-Servicemen that I nicknamed it "pensioners' heart." I can recall on two occasions seeing three necropsies on a single morning.

In 1923 Coombs (1922–23) reported 30 cases of "endocarditis lenta" seen since the end of the first world war. He distinguishes "endocarditis lenta" from the more acute type of bacterial endocarditis by the fact that it runs a course of months or years (one of his patients lived for over three years), that there is little or no fever, and that necropsy reveals anatomical evidence of stubborn opposition to the infection.

Of his patients 29 were males. A few acute cases in women, running a course not exceeding three months, were seen at the same time, but there was only one woman in the more chronic group. Of the 29 males 22 had served in the army, and 80% of these had been infantrymen or gunners with an average period of service of more than three years, mostly in France. Coombs says they were "men of fine physique and morale, men who joined the army early, served with all their might, and exerted themselves to the utmost limit of their physical powers." By contrast he did not encounter a single case among men of indifferent physique, whose service had been at the base and elsewhere, at home or overseas. He concludes that "so constant is the relation between physical fitness and strenuous exertion on the one hand, and proneness to endocardial infection on the other that a belief in the causal relation between the two can hardly be avoided." He suggests that excessive fatigue from the strenuous exertion to which these men had been subjected may have predisposed the body to infection. Possibly some similar predisposing factor may explain the high incidence of the disease during pregnancy. If this be so, it may provide a clue to the line of investigation we should pursue in searching for prophylactic measures.

The increased incidence and the more chronic nature of the disease among ex-Servicemen is emphasised by Wauchope (1925), who reviewed 125 cases of subacute and chronic bacterial endocarditis which came to necropsy at the London Hospital in 1907–24, and 70 cases, in 37 of which a positive blood-culture was obtained, admitted to hospital in 1911–23 in which no necropsy was performed. The number of male patients seen in 1922 was greatly in excess of that in previous years, whereas there was no corresponding increase in female cases. The increased incidence was due entirely to ex-Service cases. The sudden increase in 1921–22 is explained by the fact that before 1921 many Service patients were still in the army and treated in military hospitals. The reversion to the pre-war incidence in 1923 was sudden. Neither Coombs (1922–23), Starling (1922–23), nor Wauchope (1925) offers any explanation of the fact that the disease in ex-Servicemen generally runs a more chronic course than in civilians.

The same was true in Germany. Curschmann (1922) reported that at the Rostock Clinic the average number of fatal cases of subacute bacterial endocarditis in the three five-year periods between 1900 and 1915 was 8. In 1916–20 it rose to 15, and in 1921 there were 12 cases, an increase of more than 700% over the peace-time incidence. It is significant that after the 1939–45 war there was no corresponding exacerbation of "endocarditis lenta." This was a war of movement as contrasted with the static conditions of trench warfare in 1914–18. Chronic infections such as "trench foot" were less prevalent, and verminous infestation had been largely eliminated.

"Endocarditis lenta," as seen in ex-Servicemen of the 1914–18 war, presents some interesting points of contrast to the type of subacute bacterial endocarditis we see today. Its course was more chronic, the febrile disturbance was less pronounced, and often there was no rheumatic history nor evidence of any pre valvular or congenital lesion. These features suggest the infection had attacked a previously healthy and was not superimposed on a pre-existing lesion. makes one wonder whether, in view of the trivial n of the pre-existing heart disease in some, at least, of subacute cases, the supposedly "rheumatic" lesion not in reality have been produced by *Strep.* v rather than by previous rheumatic infection. hypothesis is supported by the fact that the infection of the mitral valve generally leads to but mitral stenosis is rare in subacute bacterial carditis, being present in only 2 of our 12 sup "rheumatic" cases which came to necropsy.

SUMMARY

A favourable response to penicillin may b expected in about half the patients with su bacterial endocarditis; but by earlier diagnosis we be able to improve on that figure.

Early diagnosis is often difficult, and I suggest that every patient with unexplained pyrexia, especially there be an associated heart lesion, a blood-culture be taken without delay.

The longer the infection is allowed to run on, greater the damage to the heart, and consequen greater the risk of heart-failure, which is the p cause of death.

There is a second reason why early diagnosis important. The pre-existing heart lesion is trivial and, if only we can bring these patients treatment before the infection has had time to p further damage, we may reasonably hope to render of them fit to resume their former occupations.

Unfortunately, in some cases, a progressive stenosis develops, in the course of healing; in cure of the infection appears to be directly r for the aggravation of the valvular lesion. At we have no means of dealing with this complication, perhaps our surgical colleagues may be able to help.

The high incidence of bacterial endocarditis pregnancy may prove to be a clue to the line of in tion we should pursue in searching for pre measures to combat this disease.

The discovery of penicillin has opened a new ch the story of bacterial endocarditis. There are chapters waiting to be written.

I am indebted to Dr. Morgan Jones, Dr. R. W. Fair and my other colleagues who have participated in investigation.

g. per 100 ml. On May 29 the pupils were normal. une 7 there was no neck rigidity and the patient was ng normally. When last seen, on July 28, 1948, she ared to be normal.

is was a moderately severe case probably cured streptomycin. The course of treatment was pro- ed and combined therapy was instituted, because a -negative bacillus was persistently found in the ed deposit of the C.S.F., though the culture was le. This organism subsequently proved to be a contaminant.

se 4.—A girl, aged 1 year, had become feverish and ll on Dec. 20, 1947, and had been admitted to hospital Dec. 23, with temperature 100·6°F, pulse-rate 160, rations 20 per min., injected fauces, and neck rigidity. C.S.F. had contained 480 cells per c.mm. and protein ng. per 100 ml., and on culture had grown *H. influenzæ*. ad been given sulphadiazine 1·5 g. daily for seven days penicillin 20,000 units three-hourly intramuscularly for days, 100,000 units three-hourly for another two days, 20,000 units intrathecally twice.

Dec. 30 she was transferred to the London Hospital, temperature 101°F, pulse-rate 160 and respirations r min., throat injected, nasal catarrh, well-marked neck ity. A throat swab and a blood-culture showed *H. enzæ* present. Hb 58%, white-cell count 16,400 per . (polymorphs 56%). C.S.F. contained 600 cells per . and protein 50 mg. per 100 ml., and on culture grew *fluenzæ* (1) sensitive to streptomycin.

atment.—Streptomycin 400 mg. intramuscularly daily 50 mg. intrathecally daily from Dec. 30, 1947, to Jan. 6, . The average range of the C.S.F.-streptomycin level 2–4 units per ml.

gress.—On Dec. 31, 1947, there was a remarkable ovement, the patient crawling about her cot. She had t neck rigidity, was afebrile after four days, and made eventful recovery. On Jan. 7, 1948, the C.S.F. contained mphocytes per c.mm. and protein 120 mg. per 100 ml. llow-up examination in August, 1948, showed her to be nal.

his was a moderately severe early case which vered after a single course of streptomycin.

ase 5.—A girl, aged 1 year, had been vomiting and able, but without convulsions, on Feb. 1, 1948. On 5 she had been unable to move her legs, and had been n sulphamerazine to a total dosage of 2·25 g. On Feb. 8 had been admitted to hospital with her C.S.F. containing cells per c.mm. and gram-negative bacilli. She had given sulphathiazole 1·5 g. On Feb. 9 she had been sferred to the London Hospital, with temperature 101°F, e-rate 150 and respirations 40 per min. She did not ar very ill and was mentally alert. She had slight rigidity, swelling of the right leg, especially over the le-joint; limitation of movement of the left hip, with lling in the inguinal region; and pitting œdema of both A throat swab and blood-culture both showed *H. uenzæ* present. Hb 67%, white-cell count 25,000 per m. (polymorphs 50%). Radiography of chest, pelvis, ankle showed no abnormality. Lumbar puncture duced purulent C.S.F. containing protein 80 mg. and ar 30 mg. per 100 ml. Culture produced *H. influenzæ* sensitive to a ring 15 mm. in diameter.

reatment.—Streptomycin 500 mg. intramuscularly daily n Feb. 9 to 23, and 50 mg. intrathecally daily from . 9 to 19. Both legs were immobilised in extension. average C.S.F.-streptomycin level was 8 units per ml.

rogress.—On Feb. 10, aspiration of the right ankle-joint duced a few drops of very thick pus containing gram- ative bacteria. A culture proved sterile. By Feb. 18 re was steady slow improvement, the patient being afebrile having no neck rigidity. On Feb. 25 there was an cess of the left thigh at the site of an intramuscular ction. *Staph. pyogenes* was grown from the pus. The F. was repeatedly sterile. On Feb. 19 the C.S.F. con- ned 41 cells per c.mm., protein 50 mg. and sugar mg. per 100 ml. Otherwise recovery was uneventful, l at follow-up in August the child was normal.

This was a moderately severe case, with purulent hritis of the left hip and right ankle, which recovered er a single course of streptomycin.

Case 6.—A girl, aged 1 year, had developed nasal catarrh and become drowsy and listless on Dec. 16, 1947, and had been admitted to hospital on Dec. 21 with left basal pneumonia. She had been given sulphamezathine, to a total dosage of 16 g. Her temperature had subsided at first but had risen again on Dec. 25. Chemotherapy had been discontinued on Dec. 26. On Dec. 27 she had had neck rigidity. From Dec. 28 penicillin 30,000 units four-hourly to a total of 520,000 units was given intramuscularly. On Dec. 29 her C.S.F. had contained 279 cells per c.mm. and protein 40 mg. per 100 ml., and on culture had produced *H. influenzæ*. She had then been given sulphadiazine 3 g. On Dec. 31 she was transferred to the London Hospital.

On admission her temperature was 103°F, pulse-rate 140 and respirations 30 per min. She was drowsy, with some clouding of consciousness, but was easily roused. Both ear drums were injected. The liver and spleen were just palpable. Neck rigidity was well marked. Abdominal reflexes were absent. Hb 60%, white-cell count 20,500 per c.mm. (polymorphs 48%). Blood-culture gave *H. influenzæ*, sensitive to a ring 23 mm. in diameter. C.S.F. contained 245 cells per c.mm. and protein 40 mg. per 100 ml., and on culture grew *H. influenzæ* (1).

Treatment.—Streptomycin 400 mg. intramuscularly daily and 50 mg. intrathecally daily from Dec. 31 to Jan. 8, 1948. The C.S.F.-streptomycin level was 8 units per ml.

Progress.—There was steady clinical improvement, but fever (100–102°F) persisted until Jan. 7, 1948, after which it fell to 99°F. On Jan. 8 the C.S.F. contained 60 cells per c.mm. and protein 90 mg. per 100 ml. Neck rigidity was still present on Jan. 10. On Jan. 12 the temperature was 103°F and the patient was restless and fretful, with more neck rigidity. C.S.F. contained 580 cells per c.mm. and protein 70 mg. per 100 ml., and on culture grew *H. influenzæ* (1), sensitive to a ring 15 mm. in diameter. Blood-culture proved sterile.

Further Treatment.—Streptomycin 400 mg. intramuscularly daily from Jan. 12 to 22, 100 mg. intrathecally daily from Jan. 12 to 16, and 50 mg. intrathecally daily from Jan. 17 to 22. The C.S.F.-streptomycin level was 32–64 units per ml.

Further Progress.—Steady improvement followed, temperature falling to 99°F by next day and remaining at this level, except for occasional spikes to 100°F, until Jan. 23, when it returned to normal. On Jan. 22 there was no neck rigidity, and the C.S.F. contained 72 cells per c.mm. and protein 120 mg. per 100 ml. The patient made an uneventful recovery, and at follow-up in August, 1948, appeared normal.

This was a moderately severe case, which relapsed after a full course of streptomycin, but recovered after a second course.
